ENCYCLOPÆDIA BRITANNICA.

A

DICTIONARY

OF

ARTS, SCIENCES, AND GENERAL LITERATURE.

NINTH EDITION.

(AMERICAN REPRINT.)

WITH A COMPLETE INDEX.

VOLUME XXIV.

PHILADELPHIA:
J. M. STODDART CO., Limited.
1889.

Entered, according to Act of Congress, in the year 1889, by the
EXECUTOR OF THE ESTATE OF ROGER SHERMAN, DECEASED,
In the Office of the Librarian of Congress, at Washington.

Sherman & Co.,
Printers, Philada.

Wm. Rutter & Co.,
Bookbinders, Philada.

ENCYCLOPÆDIA BRITANNICA.—VOL. XXIV.

PRINCIPAL CONTENTS.

URAL-ALTAIC LANGUAGES. Prof. A. H. Keane.
URUGUAY. Joseph Green.
USURY. Prof. J. S. Nicholson, D.Sc.
UTAH. Henry Gannett.
VACCINATION. Chas. Creighton, M.D.
VALENTINUS. Prof. A. Harnack, D.D.
VALUE. Prof. J. S. Nicholson.
VAMPIRE. Surgeon-Major G. E. Dobson.
VANDALS. Thomas Hodgkin, D.C.L.
VAN DYCK. Henri Hymans.
VARIABLE. Prof. B. Williamson.
VARIATION AND SELECTION. Prof. Patrick Geddes.
VARIATIONS, CALCULUS OF. Prof. B. Williamson.
VARRO. J. S. Reid, Litt.D.
VASCULAR SYSTEM. Prof. J. G. M'Kendrick, M.D.
VATICAN COUNCIL. Rev. Dr. R. F. Littledale.
VEDANTA. Principal A. E. Gough.
VEGA. Alfred Morel-Fatio.
VEGETABLE KINGDOM. Prof. Sydney H. Vines, D.Sc.
VELAZQUEZ. J. F. White, LL.D.
VENICE. Charles Yriarte and Prof. J. H. Middleton.
VENTILATION. Prof. J. A. Ewing.
VERMONT. Profs. G. H. Perkins and J. E. Goodrich.
VERONESE. W. M. Rossetti.
VERTEBRATA. Prof. E. Ray Lankester, LL.D.
VESICAL DISEASES. Prof. Chiene.
VESUVIUS. Archibald Geikie, LL.D.
VETERINARY SCIENCE. George Fleming, C.B., LL.D.
VETO. Prof. A. v. Orelli.
VICO. Prof. P. Villari.
VICTORIA. Alex. Sutherland.
VILLANI. Il Conte Ugo Balzani.
VINE. M. T. Masters, M. D.
  Vine Diseases. A. E. Shipley.
VIOLIN. E. J. Payne.
VIPER. St. George Mivart, Ph.D., M.D.
VIRGIL. Prof. W. Y. Sellar, LL.D.
VIRGINIA. Major J. Hotchkiss.
VITRIFIED FORTS. Rev. R. Munro.
VLACHS. A. J. Evans.
VOICE. Prof. J. G. M'Kendrick.
VOLGA. P. A. Kropotkine.
VOLTAIRE. George Saintsbury.
VOLUNTEERS. General Sir W. M. M'Murdo.
VOW. W. Robertson Smith, LL.D.
VULTURE. Prof. Alfred Newton.
WAGES. Prof. J. Shield Nicholson.
WAGNER. W. S. Rockstro.
WALDENSES. Rev. Prof. M. Creighton.
WALLACE. A. F. Hutchison.
WALLENSTEIN. James Sime.
WALPOLE. W. P. Courtney.
WAR. Col. J. F. Maurice, R.A.
  Naval Strategy. Capt. C. C. Penrose FitzGerald, R.N.
WARBURTON. R. Garnett, LL.D.
WASHINGTON, GEORGE. Prof. Alex. Johnston.
WASPS. Arthur E. Shipley.
WATCH. Lord Grimthorpe, LL.D.
WATER-SUPPLY. Prof. L. F. Vernon-Harcourt.
WATT. Prof. J. A. Ewing.
WAVE. Prof. P. G. Tait.
WAVE THEORY. Lord Rayleigh, D.C.L.
WEAVING. James Paton.
WEBER. W. S. Rockstro.
WEBSTER, DANIEL. Prof. Alex. Johnston.
WEBSTER, JOHN. A. C. Swinburne.
WEIGHTS AND MEASURES. W. M. Flinders Petrie.
WELLINGTON. C. A. Fyffe.
WESTERN AUSTRALIA. J. Bonwick.
WEST INDIES. John Gunn.
WEST VIRGINIA. John E. Kenna.
WHALE. Prof. W. H. Flower, C.B.
  Whale Fisheries. Robert Gray.
WHEAT. M. T. Masters, M.D.
  Wheat Pests. Arthur E. Shipley.
WHIST. Henry Jones.
WIELAND. James Sime.
WILKIE. J. M. Gray.
WILL. James Williams.
WILLIAM I.-IV. G. W. Prothero.
WILSON, JOHN. George Saintsbury.
WINDMILL. Prof. W. C. Unwin.
WINE. Prof. W. Dittmar and H. J. Newman.
WISCONSIN. President T. C. Chamberlin and Prof. F. J. Turner.
WITCHCRAFT. James Williams.
WOLSEY. T. W. Cameron.
WOMEN, LAW RELATING TO. James Williams.
WOOD-CARVING. Prof. Middleton.
WOOL. James Paton.
WORDSWORTH. Prof. W. Minto.
WORM. F. E. Beddard.
WRESTLING AND BOXING. E. D. Brickwood.
WRIT. James Williams.
WÜRTEMBERG. Findlay Muirhead.
WYCHERLEY. Theodore Watts.
WYCLIFFE. R. Lane Poole, Ph.D.
WYOMING. Henry Gannett.
XAVIER. Rev. Dr. Littledale.
XENOPHON. Rev. W. J. Brodribb.
YACHTING. E. D. Brickwood.
YELLOW FEVER. C. Creighton, M.D.
YEMEN. Prof. D. H. Müller.
YUCATAN. Prof. A. H. Keane.
ZACHARIAE. John Macdonell.
ZAMBESI. Prof. Henry Drummond.
ZANZIBAR. Prof. A. H. Keane.
ZEBRA. Prof. W. H. Flower.
ZECHARIAH. Prof. J. Wellhausen.
ZEND-AVESTA. Prof. K. Geldner.
ZENO. Henry Jackson, Litt.D.
ZEPHANIAH. W. R. Smith, LL.D.
ZEUS. Andrew Lang, LL.D.
ZINC. Prof. W. Dittmar.
ZODIAC. Miss A. M. Clerke.
ZODIACAL LIGHT. Prof. C. M. Smith.
ZOOLOGY. Prof. E. Ray Lankester.
ZOROASTER. Prof. K. Geldner.
ZULULAND. Francis C. Colenso and Prof. A. H. Keane.
ZURICH. Rev. W. A. B. Coolidge.
ZWINGLI. Prof. T. M. Lindsay, D.D.

AMERICAN APPENDIXES.

WENTWORTH FAMILY. F. M. Bird.
WEST POINT. N. B. Webster.
WHIG PARTY. D. O. Kellogg.

WOMEN IN THE UNITED STATES. Kate Stephens.
WORKMEN IN THE UNITED STATES. E. W. Bemis.
ZOOLOGY OF THE UNITED STATES. N. B. Webster.

ENCYCLOPÆDIA BRITANNICA.

URAL-ALTAIC LANGUAGES.

URAL-ALTAIC LANGUAGES. The Ural-Altaic, Finno-Tatar, or "Turanian" languages constitute one of the primary linguistic families (see PHILOLOGY, vol. xviii. p. 792) of the eastern hemisphere, occupying a vast domain, which extends with few interruptions from the Balkan Peninsula, Hungary, and Lapland eastward to the Pacific Ocean, and from the Arctic Ocean southwards to China proper, Tibet, and the Mediterranean. It thus comprises nearly the whole of Asiatic and a considerable section of European Russia, the northern half of the Chinese empire, a large part of north Persia, by far the greater part of Asia Minor, and extensive tracts in European Turkey, Austria, and Scandinavia, with an area of not less than 10,000,000 square miles, and a total population of over 40,000,000. Philologists recognize six well-marked branches, which, with their main subdivisions and four outlying doubtful or extinct members of the family, may be tabulated as under:

I. SAMOYEDIC.	*Yurak* and *Yenisei*, White Sea to the Yenisei. *Tavghi*, between lower Yenisei and Khatanga rivers. *Kamasin*, upper Yenisei.
II. FINNIC.	*Finnish*, Finland, part of Norway, Lakes Onega and Ladoga. *Lapp*, Russian and Scandinavian Lapland. *Esthonian* and *Livonian*, south side of Gulf of Finland. *Mordvinian* and *Tcheremissian*, middle Volga. *Permian*, *Votyak*, and *Siryenian*, between the Vyatka and Petchora rivers.
III. UGRIC.	*Ostiak*, middle and upper Obi and its eastern affluents. *Vogul*, east slopes of the Ural Mountains. *Magyar*, central and southeastern Hungary.
IV. TURKIC.	*Uigur* or *East Turki*, including *Uigur proper* of Kashgar, Kulja, and Yarkand; *Jagatai* of Bokhara, Ferghana, Khiva; *Kara-Kalpak*, southeastern side of Aral Sea; *Turkoman* (*Turkmenian*), west Turkestan, north Persia, and Asia Minor. *Seljuk* or *West Turki* or *Osmanli*, Asia Minor and the Balkan Peninsula; *Tchuvash*, southwest of Kazan and about Simbirsk. *Kipchak* (*Kapchak*): *Coman*, extinct, formerly current throughout the Kipchak empire from the Altai Mountains to the Black Sea; *Kazan Tatar*, middle Volga; *Kirghiz*, West Siberian steppes, lower Volga, the Pamir, and west slopes of the Altai, Thian-Shan, and Kuen-Lun Mountains; *Nogai* with *Kumuk*, Bessarabia, Crimea, Volga delta, Daghestan, Terek valley. *Yakut*, middle and lower Lena and northern slopes of the Sayan Mountains.
IV. TURKIC—*continued.*	*Siberian Tatar*; *Teleut*, *Koibal*, *Soyot*, *Kotta*, *Bashkir*, *Mescheryak*, and other corrupt Turki dialects spoken by Tatarized Finn populations from the Altai to the Urals.
V. MONGOLIC.	*Sharra* or *East Mongolian*, Mongolia; *Kalmuck*, Dzungaria and lower Volga, thence to lower Don; *Buriat* or *Siberian Mongolian*, east and west of Lake Baikal.
VI. TUNGUSIC.	*Tungus proper*, from the middle Yenisei to the Pacific; *Lamut*, western coast of the sea of Okhotsk; *Manchu*, Manchuria.
VII.	JAPANESE, Japan and Riu-Kiu (Lew-Chew) Islands; doubtful.
VIII.	COREAN, Corea; doubtful.
IX and X.	ACCAD and ETRUSCAN; both doubtful and extinct.

In its morphology Ural-Altaic belongs to the agglutinating order of speech, differing from other languages of this order chiefly in the exclusive use of suffixes attached to the unmodified root, and partly blended with it by the principle of progressive vowel harmony, in virtue of which the vowels of all the suffixes are assimilated to that of the root. Thus the typical formula is $R + r + r + r$, etc., where R is the root, always placed first, and r, r, r . . . the successive postfixed relational elements, whose vowels conform by certain subtle laws of euphony to that of the root, which never changes. These suffixes differ also from the case and verbal endings of true inflecting languages (Aryan, Semitic) in their slighter fusion with the root, with which they are rather mechanically united (agglutinated) than chemically fused into a term in which root and relational element are no longer separable. Hence it is that the roots, which in Aryan are generally obscured, blurred, often even changed past the possibility of identification, in Ural-Altaic are always in evidence, unaffected by the addition of any number of formative particles, and controlling the whole formation of the word. For instance, the infinitive element *mak* of the Osmanli *yaz-mak* = to write becomes *mek* in *sev-mek* = to love (vowel harmony), and shifts its place in *sev-il-mek* = to be loved (imperfect fusion with the root), while the root itself remains unchanged as to form and position in *sev-ish-il-mek* = to be impelled to love, or in any other possible combination with suffixed elements. The facility with which particles are in this way tacked on produces an exuberance, especially of verbal forms, which in Osmanli, Finnish, Magyar, Tungus, and Mordvinian may be said to run riot. This is particularly the case when the numerous modal forms become further complicated by incorporating the direct pronominal object, as in the Magyar *varjak* = they await him, and the Mordvinian *palasa* = I embrace him. Thus arise endless verbal combinations, reckoned in Turki at nearly 30,000 and past counting in the Ugrian group.

Another marked peculiarity of the Ural-Altaic, at least as compared with the inflecting orders of speech, is weak subjectivity, the subject or agent being slightly, the object of the action strongly accentuated, so that "it was done by him" becomes "it was done with him, through him, or in his place" (*apud eum*). From this feature, which seems to be characteristic of all the branches, there follow some important consequences, such as a great preponderance of locative forms in the declension,—the nominative, and often even the possessive, being expressed by no special suffix. Hence also the object normally precedes the subject, while the idea of possession (to have) is almost everywhere replaced by that of being (to be), so that, even in the highly developed Osmanli, "I have no money" becomes "money-to-me not-is" (*Akchehím yokdür*). In fact the verb is not clearly differentiated from the noun, so that the conjugation is mainly participial, being effected by agglutinating pronominal, modal, temporal, negative, passive, causative, reciprocal, reflexive, and other suffixes to nominal roots or gerunds; I write = writing-to-me-is. Owing to this confusion of noun and verb, the same suffixes are readily attached indifferently to both, as in the Osmanli *ján* = soul, *ján-ler* = souls, and *yázár* = he will write, *yázár-ler* = they will write. So also, by assimilation, the Yakut *kötördör kötöllör* = the birds fly (from root *köt* = flying), where *kötöl* stands for *kötör*, and *dör* for *lör*, the Osmanli *ler*, or suffix of plurality.

But, notwithstanding this wealth of nominal or verbal forms, there is a great dearth of general relational elements, such as the relative pronoun, grammatical gender, degrees of comparison, conjunctions, and even postpositions. Byrne's remark, made in reference to Tungus, that "there is a great scarcity of elements of relation, very few conjunctions, and no true postpositions, except those which are given in the declension of the noun,"[1] is mainly true of the whole family, in which nouns constantly do duty for formative suffixes. Thus nearly all the Ostiak postpositions are nouns which take the possessive suffix and govern other nouns in the genitive, precisely as in the Hindi: *ādmī-kī-ṭărăf* (*meṇ*) *găyā* = man-of-direction (in) I went = I went towards the man, where the so-called postposition *ṭărăf*, being a feminine noun = direction, requires the preceding possessive particle to be also feminine (*kī* for *kē*).

As there are thus only two classes of words,—the roots, which always remain roots, and the suffixes, which always remain suffixes,—it follows that there can be no true composition or word-building, but only derivation. Even the numerous Magyar nominal and adjectival compounds are not true compounds, but merely two words in juxtaposition, unconnected by vowel harmony and liable to be separated in construction by intervening particles. Thus in *aran-sinü* = gold-color = golden, the first part *aran* receives the particle of comparison, the second remaining unchanged, as if we were to say "gold-er-color" for "more golden"; and *ata-fi* = relative becomes *ata-m-fi-a* = my relative, with intrusion of the pronominal *m* = my.

But, while these salient features are common, or nearly common to all, it is not to be supposed that the various groups otherwise present any very close uniformity of structure or vocabulary. Excluding the doubtful members, the relationship between the several branches is far less intimate than between the various divisions of the Semitic and even of the Aryan family, so that, great as is, for instance, the gap between English and Sanskrit, that between Lapp and Manchu is still greater.

After the labors of Castrén, Csink, Gabelentz, Schmidt, Böhtlingk, Zenker, Almqvist, Radloff, Munkacsi-Berat, and especially Winkler, their genetic affinity can no longer be seriously doubted. But the order of their genetic descent from a presumed common organic Ural-Altaic language is a question presenting even greater difficulties than the analogous Aryan problem. The reason is, not only because these groups are spread over a far wider range, but because the dispersion from a common centre took place at a time when the organic speech was still in a very low state of development. Hence the various groups, starting with little more than a common first germ, sufficient, however, to give a uniform direction to their subsequent evolution, have largely diverged from each other during their independent development since the remotest prehistoric times. Hence also, while the Aryan as now known to us represents a descending line of evolution from the synthetic to the analytic state, the Ural-Altaic represents on the contrary an upward growth, ranging from the crudest syntactical arrangements in Manchu to a highly agglutinating but not true inflecting state in Finnish.[2] No doubt Manchu also, like its congeners, had formerly possessive affixes and personal elements, lost probably through Chinese influences; but it can never have possessed the surprisingly rich and even superabundant relational forms so characteristic of Magyar, Finn, Osmanli, and other western branches. As regards the mutual relations of all the groups, little more can now be said than that they fall naturally into two main divisions—Mongolo-Turkic and Finno-Ugro-Samoyedo-Tungusic—according to the several methods of employing the auxiliary elements. Certainly Turkic lies much closer to Mongolic than it does to Samoyedic and Tungusic, while Finno-Ugric seems to occupy an intermediate position between Turkic and Samoyedic, agreeing chiefly in its roots with the former, in its suffixes with the latter. Finno-Ugric must have separated much earlier, Mongolic much later, from the common connection, and the latter, which has still more than half its roots and numerous forms in common with Turkic, appears on the whole to be the most typical member of the family. Hence many Turkic forms and words can be explained only by reference to Mongolic, which has at the same time numerous relations to Finno-Ugric and Samoyedic that have been lost in Turkic and Tungusic. It may therefore be concluded that the Finno-Ugric migrations to the north and west and the Tungusic to the east had been completed while the Turkic and Mongolic tribes were still dwelling side by side on the Altai steppes, the probable cradle of the Ural-Altaic peoples.

How profoundly the several groups differ one from the other even in their structure is evident from the fact that such assumed universal features as unchangeable roots and vowel harmony are subject to numerous exceptions, often spread over wide areas. Not only is assimilation of final consonants very common, as in the Osmanli *bulun-mak* for the Uigur *bulul-mak*, but the root vowel itself is frequently subject to *umlaut* through the influence of suffixed vowels, as in the Aryan family. Thus in the Surgut dialect of Ostiak the long vowels of nominal stems become modified before the possessive suffix, *ā* and *ē* to *ī* and *ō* to *ū* (Castrén). It is still more remarkable to find that the eastern (Yenisei) Ostiak has even developed verbal forms analogous to the Teutonic strong conjugation, the presents *tabāq‘*, *abbatag‘an*, and *datpaq‘* becoming in the past *tobāq‘*, *abbatog‘an*, and *datpiyaq‘* respectively; so also *taig*, *tōrg*, and *tārg*, present, past, and imperative, are highly suggestive of Teutonic inflection, but more probably are due to Tibetan influences. In the same dialects, many nouns form their plurals either by modifying the root vowel, in combination with a suffixed element, or by modification alone, the suffix having disappeared, as in the English *foot—feet*, *goose—geese*. So also vowel harmony, highly developed in Finnish, Magyar, and Osmanli, and of which two distinct forms occur in Yakutic, scarcely exists at all in Tcheremissian, Votyak, and the Revel dialect of Esthonian, while in Mordvinian and Siryenian, not the whole word, but the final vowels alone are harmonized. The unassimilated Uiguric *kilur-im* answers to the Osmanli *kilur-um*, while in Manchu the concordance is neglected, especially when two consonants intervene between the root and the suffixed vowels. But too much weight should not be attached to the phenomenon of vowel harmony, which is of comparatively recent origin, as shown in the oldest Magyar texts of the 12th century, which abound in such discordances as *halál-nek*, *tiszta-seg*, for the modern *halál-nak*, *tiszta-sag*. It clearly did not exist in the organic Ural-Altaic speech, but was independently developed by the different branches on different lines after the dispersion, its origin being due to the natural tendency to merge root and suffix in one harmonious whole. The principle being thus of a purely psychological character, and necessarily an after-growth, it is not surprising to find no traces of it in the oldest and even in the later Accad texts, as seen by comparing the old *idi bar-mun-sib* with the more recent *igi mun-sib-bar*.

---

[1] *Gen. Prin. of Struct. of Lang.*, i. p. 391, London, 1885.

[2] "Meine Ansichten werden sich im Fortgange ergeben, so namentlich dass ich nicht entfernt die finnischen Sprachen für flexivische halten kann" (H. Winkler, *Uralaltaische Völker*, i. p. 54). Yet even true inflection can scarcely be denied at least to some of the so-called Yenisei Ostiak dialects, such as Kotta and others still surviving about the middle Yenisei and on its affluents, the Agul and Kan (Castrén, *Yen., Ostjak., und Kott. Sprachlehre*, 1858, Preface, pp. v-viii). These, however, may be regarded as aberrant members of the family, and on the whole it is true that the Ural-Altaic system nowhere quite reaches the stage of true inflection.

This progressive vocalic harmony has been compared to a sort of progressive *umlaut*, in which the suffixed vowels are brought by assimilation into harmony with those of the root. All vowels are broadly divided into two categories, the guttural or hard and the palatal or weak, the principle requiring that, if the root vowel be hard, the suffixed must also be hard, and *vice versa*. But in some of the groups there is an intermediate class of "neutral" vowels, which do not require to be harmonized, being indifferent to either category. In accordance with these general principles the vowels in some of the leading members of the Altaic family are thus classified by L. Adam—[1]

	Gutturals.	Palatals.	Neutrals.
Finnish	u, o, a	ü, ö, ä	e, i
Magyar	u, o, a	ü, ö	e, i
Mordvinian	u, o, a	ä, i	..
Siryenian	ô, a	ä, i, e	..
Osmanli	u, o, a, e	ü, ö, e, i	..
Mongolian	u, o, a	ṻ, ȫ, ǟ	i
Buriat	u, o, a	ü, ŏ, ǟ	e, i
Manchu	ô, o, a	e	u, i

A close analogy to this law is presented by the Irish rule of "broad to broad" and "slender to slender," according to which under certain conditions a broad (*a*, *o*, *u*) must be followed in the next syllable by a broad, and a slender (*e*, *i*) by a slender. Obvious parallelisms are also such forms in Latin as *annus*, *perennis*, *ars*, *iners*, *lego*, *diligo*, where, however, the root vowel is modified by the affix, not the affix by the root. But such instances suffice to show that the harmonic principle is not peculiar to the Ural-Altaic, but only more systematically developed in that than in most other linguistic families.

This is not the place to discuss the vexed question of the relation of the Babylonian Accad and Sumirian, or of the Etruscan, with the Ural-Altaic linguistic stock. It must therefore suffice to state in a general way that, according to the latest views, both of those long extinct languages were really branches either of the Finno-Ugric or of the Turko-Mongolic division of that family. In reply to the objection that Sumirian was a prefix language, it is pointed out that Neo-Sumirian, extinct some 1600 years before the Christian era, had already become postfixing, so that the *nin-gar* of the oldest answers to the *garra-bi* of the later texts, from root *gar* = to make. Nevertheless the point is far from settled, as may be judged from the fact that such specialists as Dr. Zimmern and Dr. Hommel are still at issue on the fundamental question of the Ural-Altaic affinities of Accad and Sumirian. The position of Etruscan is much the same, the main outcome of recent controversy being that this primitive Italian language can scarcely have been a member of the Aryan, whatever its relationship to the Finno-Tataric family.

Regarding the Japanese and Corean languages, it may be remarked that Winkler agrees with Boller in unhesitatingly including the former, while doubtfully excluding the latter from this connection. On the other hand, W. G. Aston (*Journ. Roy. Asiat. Soc.*, August, 1879) considers that both are as nearly related to one another as English and Sanskrit. The probability therefore is that Japanese and Corean are aberrant branches of the Ural-Altaic family, and that they separated at long intervals from the parent stock and at such remote periods that their affinities can no longer be clearly traced.

Bibliography.—Besides the references given above, the chief general treatises on Ural-Altaic philology are—Kellgren, *Die Grundzüge der finnischen Sprachen mit Rücksicht auf die Ural-Altaischen Sprachstämme*, Berlin, 1847; Castrén, *Ueber die Ursitze des finnischen Volkes*, Helsingfors, 1849; Id., *Syrjaen. Gram.*, *Samojed. Gram.*, and numerous other comparative grammars, dictionaries, and general treatises, chiefly on the Finno-Ugric and Samoyedic groups; W. Thomsen, *Ueber den Einfluss der germanischen Sprachen auf die Finnisch-Lappischen* (Germ. trans. by Sievers, Halle, 1870—a classical work); Abel Rémusat, *Recherches sur les Langues Tartares*, Paris, 1820; L. Adam, *Gram. de la Langue Mandchoue*, Paris, 1872, and *Gram. de la L. Tongouse*, Paris, 1874; Böhtlingk, *Die Sprache der Jakuten*, St. Petersburg, 1851; Radloff, *Volksliteratur der türkischen Stämme Sud-Sibiriens*, St. Petersburg, 1872, and "Remarks on the Codex Comanicus," *Bull. St. Petersb. Acad. Sc.*, xxxi., No. 1; Zenker, *Gram. der türkischen-tatarischen Sprachen*; Schmidt, *Mongol. Gram.*; Gabelentz, *Gram. Mandchoue*, Altenburg, 1833; Csink, *Hung. Gram.*, London, 1853; and Vambéry, *Das Türkenvolk*, Leipsic, 1885, and *Uigurische Sprach-Monumente u. das Kudatkü Bilik*, Innsbruck, 1870. For further particulars relating to the affinities and characteristics of the various branches, and of their associated members, see the articles FINLAND (vol. ix. p. 190), HUNGARY (vol. xii. p. 389), RUSSIA (vol. xxi. p. 118), TURKS (vol. xxiii. p. 703), MONGOLS (vol. xvi. p. 776), and SIBERIA (vol. xxii. p. 13). (A. H. K.)

URAL MOUNTAINS. The girdle of mountains which extends from the Arctic Ocean southwards nearly to the Caspian Sea, and is now regarded as separating Europe from Asia, was anciently the subject of various myths. Even the Slavonians, who in the 11th century frequently visited the region of the Urals for trade with the Ugrians (which people at that time lived there), described them as mountains reaching to the sky, intersected by terrible precipices, and as being inhabited by a population of cave-dwellers. Although crossed by a continuous stream of Russian colonizers from the 16th century onwards, the Ural Mountains still retained something of their mythical character in Western literature, and in the 18th century they received from geographers the high-sounding designation of *montes dicti angulus terræ*. The Russians describe them either as Kameñ (stone) merely or by the appropriate name of Poyas (girdle), while the name of Urals (*Uraly*)—derived either from the Ostiak *urr* (chain of mountains) or from the Turkish *aral-tau* or *ural-tau*—has with them become a generic name for extensive mountain chains. (See plate II. vol. xxi. and plate I. vol. xxii.)

Notwithstanding numerous scientific expeditions by which the exploration of various parts of the range began to be undertaken from the earlier portion of the 19th century, and notwithstanding partial accurate surveys and levellings and numerous geological researches made within the last thirty years, the real structure of the Urals, both orographical and geological, remains still imperfectly known. Even on maps otherwise good they are still very often represented as an unbroken chain, at least 1200 miles in length, running north and south from the Arctic Ocean to the sources of the river Ural. But every fresh addition to our knowledge has made it increasingly apparent that their real structure is much more complicated; and in view of recent explorations it becomes plain that the Urals consist of a series of several separate upheavals, some having a northwestern direction and some a northeastern, which reach their maximum heights along a zone which lies nearly north and south. They have thus some resemblance to the mountain-chains of Central Asia and Siberia,—which also have northeastern and northwestern directions, but are grouped in zones which, roughly speaking, lie west and east,—although in both cases chains running either along meridians or along parallels are, wherever they exist at all, only rare exceptions.

The composite nature of the Urals is best seen at the northern and southern extremities of the system, where the upheavals assume the character of distinct chains of mountains. The Pai-hoi Mountains are a ridge which, beginning at the head of Kara Bay, runs northwest, and is continued in the island of Vaigatch and the southern island of Nova Zembla; and the Northern Urals, which join the Pai-hoi chain at the head of Kara Bay, run northeast and southwest as far south as 64° N. lat. In their middle portion the architecture of the Urals is complicated by the plateaus of middle Russia. The southern parts do not consist, as Humboldt supposed, of ramifications from main meridional chain, but of a series of parallel ranges running distinctly from northeast to southwest, as is plainly seen in the excellent maps recently published by the Russian Geological Committee.[1] The structure of the separate parts of the Ural complexus is explained in some detail below.

---

[1] *De l'Harmonie des Voyelles dans les Langues Ouralo-Altaïques*, Paris, 1874.

I. The Pai-hoi or coast ridge (Samoyedic "stony ridge") is quite independent of the Urals proper, from which it is separated by a marshy *tundra*, some 30 miles wide. It has a distinct north-northwesterly and northwesterly trend along the shores of the Kara Sea; and, although it is cut by the Ugrian Strait, there is no doubt that it is continued in Vaigatch Island and Nova Zembla (*q.v.*). Its dome-shaped summits, which attain a height of about 1000 feet above the *tundra* (Vozaipai, 1312 feet), are completely bare of trees, and its stony crags are separated by broad marshy tundras. It is uninhabited.

II. The Obdorsk or Northern Urals, which begin within a few miles of the head of Kara Bay (Konstantinoff Kameñ, in 68° 30′ N. lat., 1490 feet), and extend in a southwestern direction as far as the 64th parallel, form a distinct ridge of mountains, stony and craggy, sloping steeply towards the southeast and gently towards the marshes of Russia. Its highest elevations are on the 66th and 67th parallels (3600 to 4370 feet). Sometimes the main chain has on the west two or three secondary ones, formed by the upheaval of sedimentary rocks, and it is towards the southern extremity of one of those that the highest peaks of the Urals occur (Sablya 5407 feet, in 64° 47′ N. lat., and Teplos-iz, 5540 feet, in 63° 55′). Dense coniferous forests, consisting chiefly of fir, pine, and larch, cover the slopes of the mountains and the narrow valleys; but, as the less hospitable latitudes are approached, every species except the larch gradually disappears and the upper limit of vegetation (2400 feet in the south) rapidly descends till it reaches the very base of the mountains towards the Arctic Circle, and forest vegetation disappears altogether about 65° lat. (67° in the plains of Russia and Siberia). These inhospitable hill-tracts, rising from the wide tundras which stretch for hundreds of miles to the west and east of the Urals, are quite uninhabited, save for a few hunters, who visit them in the summer in pursuit of the reindeer which here seek refuge from the mosquitoes of the lowlands.

III. Although usually reckoned to the Northern Urals, the section between the 64th and 61st parallels has again a wholly distinct character. It is represented on the maps as a girdle of chains, 20 to 35 miles in width, running north and south, and separated by long valleys. From the broad plateaus, or *parmas*, which stretch towards the northwest, it might be conjectured, however, that the structure is more complicated; and the recent researches by MM. Fedoroff and Ivanoff have, in fact, shown that what is described as the main chain (or, more correctly, the main water-parting) of the Urals is a succession of plateaus stretching in a northwesterly direction,[2] with broad, flat, marshy valleys, and rising here and there into isolated dome-shaped flat summits, mostly under 3000 feet (Yangtuny, 62° 43′ N. lat., 4166 feet). The whole region, except the mountain summits, is densely clothed with coniferous forests, birch appearing only occasionally in the south, and even the Scotch pine only in a few valleys. This part of the range is also uninhabited.

IV. The Middle Urals, between 61° and 55° 30′ N. lat., and about 80 miles in breadth, are the best known, as they contain the richest iron, copper, and gold mines (Bogosłovsk, Gorobłagodatsk, and Ekaterinburg Urals). The Deneshkin Kameñ in the north (4238 feet) and the Tara-tash in the south (2800 feet) may be considered as marking the limits of this section. Here the orographical structure is still more complicated, and the necessity of distinguishing the separate upheavals becomes still more apparent. In the north (61st to 60th parallel) there is a succession of chains with a distinct northeastern trend; and it still remains an open question whether, for two degrees farther south, the whole of the Bogosłovsk Urals (5135 feet in the Konjakoff Kameñ, and from 3000 to 4000 feet in several other summits) do not consist of chains having the same direction. Farther south a broad swelling, which crosses northern Russia from the Kanin peninsula in the north to the sources of the river Petchora in the southeast, joins the Urals, and is continued into Asia by the plateau of the Tura and Isset rivers. To the south of the Katchkanar (2891 feet), *i.e.*, from the 58th to the 56th parallel, therefore, the Urals assume the appearance of broad swellings from 1000 to 2000 feet in height, deeply ravined and with gentle slopes. These low and ravine-broken plateaus, the higher parts of which can be reached from Russia on a very gentle gradient, have been utilized for centuries as the chief highway to Siberia. They have none of the aspects of an alpine tract; and the traveller to Siberia cannot but experience a feeling of disappointment as his horses, still running at full speed, reach the marble column, inscribed "Europe" on one side and "Asia" on the other, which marks the water-parting (1180 feet) between the Russian and Siberian rivers. The eastern slope is steeper, but even there Ekaterinburg is only 350 feet below the water-parting. The valleys have a decidedly southeastern direction, and such is also the course of the railway from Perm to Tyumeñ, as soon as it reaches the Siberian slope. The plateau-like swellings of this division terminate farther south in a depression, about 70 miles broad, stretching from northwest to southeast, where the water-parting has a height of only a few hundred feet. The Middle Urals are still densely forested, notwithstanding the immense quantities of timber and fuel which are constantly being taken from them. The vegetation is much more varied than in the north (birch, oak, lime, and maple), a rich undergrowth of bushes growing together with the conifers, and the banks of the rivers being adorned with the wild cherry (*Prunus padus*), poplar, willow, and alder. The valleys and lower slopes are covered with a thick sheet of rich humus and have become the site of large and wealthy villages. The mines also have given rise to a considerable population. The southern parts of the Middle Urals may be estimated to have a total agricultural and mining population of nearly 1,500,000.

V. The Southern Urals (from 55° 30′ to 51° N. lat.) are now well known both orographically and geologically;[3] and it appears that, instead of consisting of three chains of mountains radiating from Mount Yurma, as was formerly supposed, they consist of a series of three parallel chains running northeast and southwest, and therefore constitute a quite independent part of the Ural complexus. The Ural-tau proper is a low sinuous chain extending due southwest and hardly exceeding 2200 to 2800 feet in height. It slopes gently towards the northwest and abruptly towards the southeast, where several short and low chains (Ilmeñ, Irenły, etc.) rise in the basins of the Mias and the Ui. In the west a chain separated from the Ural-tau by a longitudinal valley accompanies it throughout its entire length. This, although pierced by the rivers which rise in the longitudinal valley just mentioned (Ai, upper Byełaya), nevertheless rises to a much greater height than the Ural-tau. Its wild stony ridge has an altitude of 3375 feet in the Yurma, and 3950 feet in the Taganai; while the Urenga and Iremel Mountains exceed 3500 feet, and the peaks bearing these names reach 4013 and 5040 feet respectively. Farther west, another series of chains, parallel to the above, is described under various names (Zurat-kul, Zigałga, Nary); they reach nearly the same altitudes (Zigałga and Yaman-tau, 4880 and 5400 feet respectively). A number of other chains, also parallel and ranging from 2000 to 3000 feet, accompany them in the west. The whole system has thus the character of a swelling nearly 65 miles wide, intersected by a series of parallel chains, the results of as many foldings of the sedimentary rocks, which have undergone extensive denudation. Some of the chains are exceedingly craggy, and most of them are covered with masses of angular *débris*, sometimes concealed under thick sheets of marshy mosses. The gorges by which the rivers pierce the Devonian limestones on their way towards the lower terraces are most picturesque in the west, where the Urals assume an alpine character. The forests are no longer continuous; the gentle slopes of the hilly tracts are dotted with woods, mostly of deciduous trees, while the hollows contain rich pasture grounds. The thick layers of sedimentary rock which are lifted *en masse* on the western slope cover a wide area farther to the west in the shape of a plateau which already assumes the features of a steppe (see Ufa). The whole region, formerly the abode of Bashkirs, is rapidly being colonized by Russians.

Farther south, between the 53d and 51st parallels, the Ural-tau, still composed of crystalline rocks (diorite, serpentine, granite), continues in the same direction, but is covered as we advance by horizontal Cretaceous deposits and, except when deeply trenched by rivers, assumes the appearance of a plateau which hardly reaches 1500 feet. It is continued farther southwest (towards the Volga) under the name of Obschiy Syrt. A narrow longitudinal valley watered by the Sakmara (right-hand tributary of the Ural) separates the Ural-tau and the Guberlinsk Mountains (as the preceding tract is called) from the Irendyk chain, about 20 miles in width, which reaches 2300 feet in its higher parts. It is cut by the Ural river at Orsk and extends farther southwest towards the sources of the Ilek; while in the east a wide granitic plateau, with only a few remainders of its former Devonian and Carboniferous covering, some 130 miles broad and nearly 1000 feet high, lies about the sources of the Siberian rivers, and is known by such local names as Kara-Edyr-tau, Djabik-Karagai, and the like.

VI. As a rule the Urals are not shown on maps to the south of the great bend of the Ural river, where quite independent ranges of hills, or flat swellings, are represented (Jaman-tau, Mugojar Hills). It appears, however, from recent exploration[1] that the Mugojar Hills may safely be regarded as a farther continuation of the upheavals which constitute the Urals. The Cretaceous plateau north of the Ural river is continued to the south of it; it again assumes a mountainous character in the Jaman-tau (50° N. lat.) and joins the Mugojar Hills, which consist of diorites and crystalline slates and reach their maximum in the Airuk Mountain (about 1000 feet). A range of heights connects the Mugojar Hills with the Ust-Urt plateau (see TRANSCASPIAN REGION). It is hardly necessary to say that these plateaus and flat hills to the south of the river Ural have all the characters of the Ciscaspian and Transcaspian steppes.

Geology.—Whatever the variety of the orographically independent systems of mountains and plateaus embodied under the general name of Urals, a certain "geotectonic" similarity may be observed in all of them. Denudation has been active on so grand a scale that entire strata of sedimentary deposits have been removed from their original positions and scattered in the form of *débris* to distances of more than 100 miles on both sides of the Urals, so as considerably to reduce their former height. But, if this agency be taken into account, the Urals seem to come under the category of what the Germans call asymmetric *Faltengebirge*, and thus exhibit a great resemblance to the western Alps. A broad strip of granites, syenites, diorites, and porphyries, with their subordinate gneisses and crystalline slates, belonging to the Laurentian and Huronian systems, constitutes the main axis of upheaval, and this axis is invariably situated in the eastern part of the mountain region. The asymmetry thus resulting is the more pronounced as the Azoic rocks are mostly covered directly by Tertiary and Quaternary deposits on their Siberian slope; while towards the west they are covered with vast layers of Silurian, Devonian, Carboniferous, Permian, and Triassic rocks, which are manifoldly folded so as to constitute a series of chains parallel to the main axis and mostly lifted to much greater heights than the older Azoic rocks.

The crystalline rocks which must have constituted the primary ridges mostly appear in the shape of plateaus, water and glacier-worn, with undulating surfaces; and the hills which rise above the plateaus are mostly dome-shaped and are seldom marked by the craggy characters which are met with in the limestone and sandstone mountains of the subsequent formations. Masses of angular *débris* and great blocks cover both the plateaus and the mountains; and only a very few traces of the sediments which may have partially covered the Azoic crystalline rocks are sporadically met with. But, as a rule, they have remained a continent since the Huronian epoch. As for the Primary and Secondary deposits of the western slope, they are represented by Silurian, Devonian, Carboniferous, Permio-Carboniferous, Permian, and Triassic deposits, attaining great thicknesses and following one another in succession so as to appear on the surface as strips lying parallel to the Urals. The strip occupied by the Silurian quartzites, limestones, and slates is narrow, even in its northern portion. Farther south it disappears, and the deposits which formerly were assigned to the Silurian period are now considered to be mostly Devonian. These latter, mostly littoral in character and much resembling those of the Eifel and Belgium, occupy wide areas to the west of the main axis of the Urals. Their lower parts are much metamorphosed. The Carboniferous deposits,—coal-bearing in the Middle and Southern Urals,—although appearing at the surface only as a narrow strip in the west Urals, occupy an extensive area, but are concealed by the largely developed Permian deposits, and that series of sediments which must be considered as intermediate between the Carboniferous and the Permian. These latter, described as "Permo-Carbon" by Russian and German geologists, are largely developed in the west Urals. Their fossils belong to a fauna intermediate between the Carboniferous and the Permian, which was formerly known as that of Artinsk; but since two more series of the same intermediate character have been described the whole has been brought under the general name of Permio-Carboniferous deposits. The Permian deposits cover a wide zone all along the western slope of the Urals from north to south, and are most important on account of their copper ores, salt-beds, and salt-springs. They are also covered with variegated marls which are almost quite destitute of fossil organisms, so that their age is not yet quite settled. Some Russian geologists continue to consider them as Permian, while the majority of recent explorers assign them to the Triassic age.

The glaciation of the Urals is still a debated question. Even those geologists who now acknowledge that the Scandinavian ice-sheet covered middle Russia hesitate to admit the existence of an ice-cap covering the Middle and Southern Urals,—the want of polished and striated rocks being the chief argument for the negative. But, if the disintegrated state of the rocks which are best fitted to maintain glacial polishing and striation, their thick coverings of *débris*, and the action of lichens and mosses in obliterating the traces of glaciation be taken into account, as also the prevalence of erratic blocks, and the character of the deposits filling up the valleys, it must be regarded as most probable that the Urals, too, must soon be included within the limits of former glaciation (as has been already done by a few explorers, such as Polyakoff). The Lacustrine (Post-Glacial) deposits are widely spread all over the slopes of the Urals. Immense marshes, which have recently emerged, in the north, and numberless lakes in the south, which are but small in comparison with their size at a recent period, as also Lacustrine deposits in the valleys, all go to show that during the Lacustrine period the Urals were as much dotted with lakes as Finland is at the present time.

Climatic, Geo-Botanical, and Geo-Zoological Importance.—The importance of the Urals as a climatic and geo-botanical boundary can no longer be regarded as very great. Most European species of plants freely cross the Urals into Siberia, and several Siberian species travel across them into northern Russia. But, being a zone of hilly tracts extending from north to south in a meridional direction, the Ural Mountains necessarily exercise a powerful influence in driving a colder northern climate, as well as a northern flora and fauna, farther towards the south along their axis. The harshness of the climate at the meteorological stations of Bogosłovsk, Złatoust, and Ekaterinburg is not owing merely to their elevation a few hundred feet above sea-level. Even if reduced to sea-level, the average temperatures of the Ural meteorological stations are such as to produce a local deflection of the isotherms towards the south. The same is true with regard to the limits of distribution of vegetable and animal species. It has been already stated that the northern limits of tree-vegetation descend towards more southern latitudes on the Northern Urals and in the vicinity of the chain. The same is true with regard to many other species of plants. In like manner several Arctic species of animals come much farther south than they might otherwise have done: the reindeer, for instance, is met with as far south as the 52d parallel. The Southern Urals introduce amidst the Ciscaspian steppes the forest vegetation, flora, and fauna of middle Russia.

In the distribution of the races of mankind the Urals have also played an important part. To the present day the Northern Urals are the abodes of Finnish stems (Samoyedes, Zyrians, Voguls, and Permians) who have been driven from their former homes by Slavonian colonization, while the steppes on the slopes of the Southern Urals have continued to be inhabited by the Turkish stems of the Bashkirs. The Middle Urals were also in the 9th century the abode of the Ugrians, and their land, Biarmia (now Perm), was well known to the Byzantine historians for its mineral wealth,—there being at that time a lively intercourse between the Ugrians and the Greeks. Compelled to abandon their abodes, they moved south on the Ural slopes towards the land of the Khazars, and through the prairies of southeastern and southern Russia (the *Λεβεδία* of Constantine Porphyrogenitus) towards the Danube and to their present seat—Hungary,—leaving but a very few memorials in the Northern and Middle Urals.[2] At present the Urals, especially the Middle and the Southern, are being more and more colonized by Great Russian immigrants, while the Finnish stems are rapidly melting away.

Metallurgy and Mining.—The mineral wealth of the Urals was known to the Greeks in the 9th century, and afterwards to the Novgorodians, who penetrated there in the 11th century for trade with the Ugrians. When the colonies of Novgorod (Vyatka, Perm) fell under the rule of Moscow, the Russian czars soon understood the importance of the Ural mines, and Ivan III. sent out German engineers to explore that region. In 1558 the whole of the present government of Perm was given by the rulers of Moscow to the brothers Strogonoff, who began to establish salt-works and mines for iron and copper. Peter I. gave a new impulse to the mining industry by founding several iron-works, and from 1745, when gold was first discovered, the Russian colonization of the Urals took a new departure. The colonization was, however, of a double character, being partly free—chiefly by Nonconformists in search of religious freedom in the wildernesses of the Urals—and partly compulsory,—the Government sending peasant settlers who became serfs to the iron and copper works, and were bound to supply them with ores and wood for fuel. Until 1861 all work at the mines was done by serfs belonging either to private persons (the Strogonoffs, Demidoffs, and others) or to the crown. At present (1888) only a few works, maintained for supplying the army, belong to the crown.

Gold is found both in veins and in alluvial or diluvial deposits, and is extracted from both; but the former yield only a moderate quantity annually (2180 to 2780 ℔ in 1882–84). The gold from the Ural mines constitutes nearly one-fifth of the total amount obtained throughout the Russian empire. Platinum is found either in connection with gold dust or separately, the platinum mines of the Urals being the only ones worked in Russia. Osmium, iridium, and nickel are found at several places, but their industrial importance is small. Silver is also met with at several places, but only 2383 ℔ were extracted during the years 1875 to 1884. The copper mines, chiefly in Perm, but partly also in Ufa, are very important, nearly two-thirds of the total amount of the metal mined in Russia being obtained from eight works in the Urals. The average amount of gold, platinum, and copper annually yielded by the Ural mines is given in the following table:

	Gold.	Platinum.	Copper.
	℔.	℔.	cwts.
1860-64	11,296	...	78,500
1865-69	13,997	3666	60,880
1870-74	13,845	3890	45,310
1875-79	16,114	4048	30,508
1880-84	18,042	6949	48,004

Iron is widely diffused and is extracted in the governments of Perm, Ufa, and Orenburg, the chief works being in Perm. Of the 198 blast furnaces in the Russian empire 103 are in the Urals, and they supply nearly two-thirds of all the pig-iron produced in Russia. One-half of the iron and one-sixth of the steel obtained both from home and foreign pig-iron in the empire are prepared in the Urals; and, while the St. Petersburg and Polish steel works, which prepare steel (chiefly for rails) from imported iron, show great fluctuations in their production, the Ural works have a steady increase. The average yearly production of iron in the Urals is best seen from the following:

	Pig-Iron.	Iron.	Steel.
	cwts.	cwts.	cwts.
1875–80	6,623,000	3,406,000	259,600
1881–83	6,378,000	3,517,000	612,800
1884	6,740,000	3,874,000	763,340

Owing to the immense extent of forest, the coal mining industry is but of recent origin in the Urals. Only six pits were at work in Perm in 1884; and of recent years from 3,000,000 to 4,000,000 cwts. have been annually extracted (about 5 per cent. of the coal raised in the Russian empire). Finally, salt was raised in Perm, Orenburg, and Uralsk to the amount of 9,422,000 cwts. in 1884.

The precious (amethyst, topaz, emerald, tourmaline, etc.) and ornamental (malachite, carsovite, etc.) stones of the Urals are familiar in all European museums, and are found in most beautiful varieties. The crown works at Ekaterinburg supply admirable works of art, while a numerous population at Ekaterinburg and in the neighboring villages support themselves by searching for precious and ornamental stones and preparing them for export. Of the 330,750 workmen engaged in 1884 in mining and metallurgical industries throughout the Russian empire 183,914 were employed in the Urals, as well as nearly one-half of the motive power (steam-engines and water-wheels) used at the mining and metallurgical works of Russia, Poland, and Finland. The exports from the Urals are made chiefly by means of the rivers, which are navigable in their upper parts only during the spring. There is not as yet any railway connecting the Urals with Russia. The line of Siberian railway which now connects the iron-works of the eastern slope with the Kama at Perm has certainly increased the exports; but they are still so small in comparison with the expense of the line that the railway is worked at a loss, the deficiency being made good from the imperial budget, and the whole mining and metallurgical industry of the Urals is still maintained by means of high protective duties imposed on foreign metals and metallic wares.

Several wealthy towns have grown up in the Ural valleys in connection with mining industry and administration. **Ekaterinburg** (*q.v.*) and **Nijne-Taghilsk** (*q.v.*) both had more than 30,000 inhabitants in 1885, while **Zlatoust** (*q.v.*), Neviansk, Neivinsk, and Kyshtym in Perm, Votkinsk and Izhevsk in Vyatka, had from 21,000 to 12,500 inhabitants. The Revdinsk, Bogosłovsk, Turinsk, Shaitanovsk, Gorobłagodat, Artinsk, Nijne-Saldinsk, Usolie, and Sysertsk mining towns in Perm, Katav-Ivanovsk, Kusinsk, and Satkinsk in Ufa, Byełoryetsk, Tirlansk, and Avzyano-Petrovsk have populations from 5000 to 10,000.

Mezhoff and those of the Kieff Society of Naturalists.

(P. A. K.)

URALSK, a province of southeastern Russia, lying to the north of the Caspian Sea, with an area of 141,174 square miles. It is bounded by Astrakhan on the west, Samara and Orenburg on the north, Turgai and the Sea of Aral on the east, and the Transcaspian Region on the south. It is geographically situated mostly within the boundaries of Asia, *i.e.*, to the east of the Ural river, and both its physical features and its inhabitants are, to a very large extent, Asiatic. Administratively, it belongs to the "Kirghiz provinces," or governor-generalship of the steppes. Apart from a narrow strip of land in the north, where the slopes of the Obschiy Syrt, covered with a fertile black earth and stretches of forest, descend towards the Ural river, and the gentle slopes of the Mugojar Hills in the northeast, Uralsk consists of dry steppes and deserts, which fall with an imperceptible gradient towards the Caspian. Most of the province is below sea-level, the zero-altitude line running from Kamyshin on the Volga to the south of the town of Uralsk. The steppe-land consists for the most part of sandy clay, sands containing shells of molluscs now living in the Caspian, salt clay, and shifting sands. It is also dotted with numerous salt lakes, partly remains of old lagoons of the Caspian. To the southeast Uralsk extends over the northern part of the Ust-Urt plateau. Red sandstones (Permian?) and chalk are met with only in the north, the remainder of the province being covered with Post-Pliocene Caspian deposits, which conceal the underlying rocks.

Uralsk is watered by the Ural, which rises in Orenburg at a height of 2100 feet above sea-level, but soon descends to the lowlands, where it flows south, west, and south, entering the Caspian after a course of 800 miles. Its chief tributaries, the Sakmara, the Or, and the Ilek, are in the north; along its lower course the Great and Little Uzeñs and many small streams on the left bank fail to join the main river, being lost in lakes before reaching it. The Emba, which has its course in the north of the Ust-Urt plateau, reaches the Caspian by a series of shallow lagoons which were navigable in the 18th century.

The climate is influenced by the Central Asian steppes. A cold and dry winter is succeeded by a hot and still drier summer, during which the grass, and sometimes all the crops, are destroyed by the burning heat. Uralsk, although lying wholly to the south of 51° 30′ N. lat., has the same average yearly temperature as Moscow and south Finland (39.5°); its January is colder than that of north Finland (3°), while July averages 73°.

The character of the vegetation can be easily inferred from the above. The prairies and forest tracts of the north soon disappear, their place being taken by the vegetation of the south Russian steppes. This has, however, to struggle with the much poorer vegetation, Central Asian in character, of the sandy regions to the west of the lower Ural, and the saliniferous vegetation of the clayey deserts of the Emba. The Ust-Urt has herbaceous steppes, where the want of irrigation and rain destroys all vegetation by the end of summer. Wide belts of rushes grow along the banks of the rivers and on the shores of the Caspian.

The population of the province, 525,330 in 1883, is made up of three different elements,—Ural Cossacks, who constitute about one-fifth, and numbered nearly 90,000 in 1879, some 15,000 Russian peasants, and Kirghiz. Of these 405,000 are still nomads. The Kirghiz are almost entirely dependent on cattle-breeding, and before the outbreak of the murrain of 1879 were reckoned to have 429,500 horses, 221,800 head of cattle, 1,411,000 sheep, and 175,000 camels. From that epidemic the Russians lost two-thirds of their horses and one-third of their other stock, whilst the Kirghiz lost more than three-fourths of both horses and cattle. The Ural Cossacks, descendants of those independent communities of free settlers and Raskolniks who are so often mentioned in Russian history under the name of Yaik Cossacks, owing to their unwillingness to submit to the rule of the czars, are fine representatives of the Great Russian race, though not without some admixture of Tartar and Kalmuck blood. Their chief occupations are cattle-breeding and fishing, the latter a most important source of income. The rich fisheries in the Ural and the Caspian are the property of the community as a whole (the *voisko*), and are subdivided according to the needs and working powers of the separate villages.[1] They give employment to about 7000 Cossacks and 2000 hired laborers. There are also fisheries in the Emba. Walrus-hunting is also engaged in. Agriculture was first introduced between 1830 and 1840; but now more than 300,000 cwts. of wheat are exported annually. Nearly 130,000 cwts. of salt are obtained from the lakes every year. The manufactures of the province, which possesses a few steam flour-mills and a number of tanneries and tallow-melting works, are unimportant. Trade by barter is extensively carried on with the Kirghiz. Fish, corn, cattle, hides, tallow, and the like are exported, while manufactured wares are imported to the value of about £1,500,000 [$7,290,000] per annum.

Uralsk is divided into four districts, the chief towns of which are—Uralsk (20,680 inhabitants in 1879), Kalmykoff (1510), Gurieff at the mouth of the Ural (4380), and Temirsk, a small port, now the administrative centre of the district of Embinsk. Several villages have populations of from 2000 to 5000 each.

History.—In the first half of the 16th century Uralsk was occupied by the Nogai horde, a remnant of the Golden Horde, which retired there after the fall of Astrakhan and Kazan; the khans resided at Saraitchik on the Ural. At the same time the lower parts of the Ural were occupied by Russian runaway serfs and free Cossacks who did not recognize the authority of Moscow. They took Saraitchik in 1560 and formed an independent community, like the *sitch* of the Zaporog Cossacks. The Moscow princes, recognizing the importance of these military settlements, tried to win their allegiance by the grant of various privileges. But, when they attempted to bring them under the centralized rule of the empire and prosecuted them for nonconformity, the Cossacks revolted, first under Razin, and afterwards under Pugatcheff. After the latter rising, the name of Ural was officially given to the Yaik river and the Yaik Cossacks. The disbanding of their artillery, the planting of Russian garrisons within the domains of the *voisko*, and the interference of Russian officials in their interior organization during the 19th century occasioned a series of smaller outbreaks, the latest of which, in 1874, against the new law of military service, resulted in the deportation of 2500 Cossacks, with their families, to Turkestan.

URALSK, capital of the above province, is situated on the upper Ural, at its confluence with the Tchagan, 1095 miles southeast from Moscow. The town is well built, with regular streets; among its prominent buildings are the theatre, the club, and two gymnasiums; and it is beautified by numerous gardens. The scientific society issues publications of great value. There is a very brisk trade in fish, cattle, hides, tallow, grain (exported), and in manufactured goods (imported). The population in 1879 was 20,680.

URANIUM, the name of a rather rare metallic element, already briefly referred to under CHEMISTRY (vol. v. p. 469). The credit of its discovery as an element must be assigned to Klaproth, who in 1789 isolated from pitch-blende a yellow oxide which, while obviously metallic, was foreign to all the known metals. He accordingly viewed it as the oxide of a new metal, which he named uranium, after the newly discovered planet of Herschel. From the yellow oxide he obtained, by reduction with charcoal at a high temperature, what he took to be metallic uranium. Berzelius about 1823 found that the yellow oxide, when treated with excess of sulphuric acid, united with it into a sulphate, not unlike the ferric salt $Fe_2O_3.3SO_3$ in its character. Hence he concluded that the uranium salt is $Ur_2O_3.3SO_3$, where Ur_2O_3, according to his analysis, represents 864 parts of yellow oxide, if $Fe_2O_3 = 160$ or $O = 16$. Like Fe_2O_3, the yellow oxide lost 48 parts of oxygen per $Ur_2O_3 = 864$ parts as water, while $Ur_2 = 816$ parts of metal remained.[2] These results were universally adopted until Péligot in 1840 discovered that Berzelius's (and Klaproth's) metal contains oxygen, and that his $(Ur_2)O_3$ really is $(U_6O_6).O_3 = 3U_2O_3$, where $U = 120$ is one atomic weight of real uranium. Péligot's results, though called in question by Berzelius, have been amply confirmed by all subsequent investigators; only now, on theoretical grounds, first set forth by Mendeljeff, we have come to double Péligot's atomic weight, so that throughout this article U signifies 240 parts of uranium, while UO_3 stands as the formula of the yellow oxide, and UO_2 as that of Berzelius's metal.

The only practically available raw material for the extraction of uranium is pitch-blende (Germ. and Fr. *Uranpecherz*), which occurs associated with lead and silver ores, chiefly in Joachimsthal and at Przibram in Bohemia, at Schneeberg in Saxony, and at Redruth in Cornwall, forming greenish or brownish black masses clustering together like grapes. Its hardness is 5.5. The specific gravity varies from 6.4 to 8, the mineral almost invariably presenting itself in intimate intermixture with a host of foreign metallic compounds, such as sulphides, arsenides, etc. Pure pitch-blende is U_3O_8, which in relatively good specimens forms some 80 per cent. or more of the whole.

In the chemical treatment of the ore, it is expedient to begin by removing at least part of the arsenic and sulphur of the admixtures by roasting, and then to wash away the light oxides with water or dissolve them away with hydrochloric acid. In one of the many processes proposed the purified ore is disintegrated with hot nitric acid, to produce nitrates, which are then converted into sulphates by evaporation with oil of vitriol. The sulphates are treated with water, which dissolves the uranium and other soluble salts, while silica, sulphate of lead, etc., remain; these are removed by filtration. From the solution the arsenic, copper, etc., are precipitated by sulphuretted hydrogen as sulphides, which are filtered off. The filtrate contains the uranium as uranous and the iron as ferrous salt. These are oxidized by means of chlorine or some other oxidizing agent, and precipitated conjointly by excess of ammonia. The precipitate, after having been collected and washed, is digested with a warm concentrated solution of carbonate of ammonia, which dissolves the uranium as a yellow solution of uranate of ammonia, while the hydrated oxide of iron, the alumina, etc., remain. These are filtered off hot, and the filtrate is allowed to cool, when crystals of the uranate separate out. The mother liquor includes generally more or less of nickel, cobalt, zinc, and other heavy metals, which, as Wöhler showed, can be removed as insoluble sulphides by the addition of sulphide of ammonium; uranium, under the circumstances, is not precipitated by sulphide of ammonium. The filtrate, on being boiled down, yields a second crop of uranate of ammonia. This uranate when ignited in a platinum crucible leaves a green oxide of the composition U_3O_8, *i.e.*, artificial pitch-blende, which serves as a starting point for the preparation of uranium compounds. The green oxide, as a rule, requires to be further purified. One method for this purpose is to convert it into a solution of the nitrate $UO_2(NO_3)_2$, and from it to precipitate the metal as oxalate by the addition of oxalic acid (Péligot). The latter ($UO_2.C_2O_4$) yields a purer oxide, UO_2, or, in the presence of air, U_3O_8, on ignition.

---

[1] See Haxthausen's *Russia* for a description of the Cossack community; comp. also the more recent works of Ryabinin and Khoroshkhin and many separate monographs in Russian periodicals; also Baer's *Kaspische Studien* and Danilevsky on the fishing.

[2] We substitute for Berzelius's actual numbers the corresponding values calculated from our present constants.

Metallic uranium, as shown by Péligot, can be obtained by the reduction of a mixture of dry chloride of potassium and dry uranous chloride, UCl_4, with sodium at a red heat (for details see handbooks of chemistry). The metal, which is easily separated from the slag by treatment with water, remains as a dark heavy powder or in white compact globules, according to the temperature at which it was produced. According to Zimmermann, to whom we owe a recent investigation on the matter, pure compact uranium is a white malleable metal, which is pretty hard, though "softer than steel." Its specific gravity has the high value 18.7; its specific heat is 0.02765, corresponding to $U = 240$. The fusing point, from Zimmermann's statements on its preparation, seems to lie at bright redness. The compact metal when exposed to the air tarnishes only very slowly. The powdery metal when heated in air to 150° or 170° C. catches fire and burns brilliantly into U_3O_8. Dilute sulphuric acid attacks it but slowly; hydrochloric acid, especially if strong, dissolves it readily, with the formation, more immediately, of a hyacinth-colored solution of U_2Cl_6, which, however, readily absorbs oxygen from the air, with the formation of a green solution of UCl_4, which in its turn gradually passes into one of yellow uranyl salt, $UO_2.Cl_2$.

Uranous Compounds.—The oxide UO_2 (Berzelius's metal) is prepared by heating the green oxide U_3O_8 in hydrogen. It dissolves in hot oil of vitriol; the mass, when treated with water, dissolves; from the solution green crystals, $U(SO_4)_2 + 8H_2O$, are obtainable. The anhydrous chloride UCl_4 was prepared for the first time by Péligot by heating an intimate mixture of the green oxide and charcoal to redness in a current of dry chlorine; it is obtained as sublimate of black-green metallic-looking octahedra. The chloride is very hygroscopic. Uranous salts pass into uranic (uranyl) compounds under the same circumstances under which ferrous salts become ferric, only they do so far more readily.

Uranic Compounds.—By keeping the nitrate $UO_2(NO_3)_2$ at a temperature of 250° for a sufficient time the oxide UO_3 is obtained as a chamois-yellow solid, insoluble in water, but soluble in acids, with the formation of uranyl salts, $UO_2.Cl_2$, etc. The oxide, in other words, behaves to acids as if it were the monoxide of a radical (UO_2) uranyl. This sulphate $(UO_2)SO_4 + 3$ or $3.5H_2O$ is deposited from a syrupy solution in yellow crystals. The nitrate $(UO_2)(NO_3)_2 + 6H_2O$ forms large yellow crystals easily soluble in water. The salt is used in photography, also in analysis as a characteristic precipitant for phosphoric acid. If a solution of a uranyl salt is mixed with one of ammonia, or potash, or soda, the uranium is precipitated in the form of a uranate, $U_2O_6R_2O$, of the respective alkali. Uranate of soda, forming yellow crystals of the composition $Na_2U_2O_7 + 6H_2O$, is made industrially, being used for the production of yellow uranium glass in porcelain painting. The Joachimsthal works in 1875 produced 70 cwts. of this "oxide," representing a value of £8500 [$41,310].

Analysis.—A borax bead dissolves uranium oxides in the reducing flame with a green, in the oxidizing flame with a yellow, color. Solutions of uranyl salts (nitrate, etc.) behave to reagents as follows: sulphuretted hydrogen produces green uranous salt with precipitation of sulphur; sulphide of ammonium in neutral solutions gives a black precipitate of UO_2S, which settles slowly and, while being washed in the filter, breaks up partially into hydrated UO_2 and sulphur; ammonia gives a yellow precipitate of uranate of ammonia, characteristically soluble in hot carbonate of ammonia solution; prussiate of potash gives a brown precipitate which in appearance is not unlike the precipitate produced by the same reagent in cupric salts. (W. D.)

URANUS (*i.e.*, Heaven) is in Greek mythology the husband of Gæa (Earth) and father of Cronus (Saturn) and other deities. See MYTHOLOGY, vol. xvii. p. 161, and SATURN.

URBAN, St., first pope of that name, was bishop of Rome from 222 to 230. He had been preceded by Calixtus and was followed by Pontianus. He is mentioned by Eusebius (*H. E.*, vi. 23), and is named in an inscription in the cœmeterium Callisti, but of his life nothing is known. The Roman *Breviary* (25th May) speaks of his numerous converts, among whom were Valerianus, husband of St. Cecilia, and his brother Tiburtius, and states that he suffered martyrdom, and was buried in the cœmeterium Prætextati.

URBAN II. (Eudes or Odo), pope from 1088 to 1099, was born of knightly rank, at Lagery (near Châtillon-sur-Marne), and was educated for the church. He had already become archdeacon of Rheims when, under the influence of St. Bruno, his teacher, he resigned his preferment and entered the cloister at Cluny, where he rose to be prior. In 1078 Gregory VII. summoned him to Italy, and made him cardinal-bishop of Ostia. He was one of the most prominent and energetic supporters of Hildebrandism, especially as legate in Germany in 1084, and was among the few whom Gregory nominated as possible successors. Desiderius of Monte Casino (Victor III.) was chosen in the first instance to the difficult post, but at the next vacancy Odo was elected by acclamation (March, 1088) at a small meeting of cardinals and other prelates held in Terracina. He frankly took up the policy of his great predecessor, but while pursuing it with equal determination showed greater flexibility and diplomatic finesse. At the outset he had to reckon with the presence of the powerful antipope Clement III. in Rome; but a series of well-attended synods held in Rome, Amalfi, Benevento, and Troia supported him in renewed declarations against simony, lay investiture, and clerical marriages, and a continued policy of opposition to Henry IV. In accordance with this last policy, the marriage of the countess Matilda with Guelph of Bavaria was promoted, Prince Conrad was helped in his rebellion against his father and crowned king of the Romans at Milan in 1093, and the empress (Adelaide or Praxedes) encouraged in her disgraceful charges against her husband. In a protracted struggle also with Philip I. of France, whom he had excommunicated, Urban II. finally proved victorious. But the most prominent feature in his pontificate, a feature indeed which marks an epoch in the history of Latin Christianity, is his connection with the first crusade (see CRUSADES, vol. vi. pp. 550), which united Christendom under the headship of the pope into one vast warlike confederacy (comp. POPEDOM, vol. xix. p. 513). The crusading movement first took shape at Piacenza, where in March, 1095, Urban received an embassy from the emperor Alexius I., asking help against the infidel, and where a great council met, attended by numerous Italian, Burgundian, and French bishops and by so vast a concourse of monks and laymen that the public meetings had to be held in the open air outside the city. The still more enthusiastic council of Clermont was held in November of the same year. Urban II. died on 29th July, 1099, fourteen days after the fall of Jerusalem, but before the tidings of that great event had reached Italy; his successor was Paschal II.

URBAN III. (Uberto Crivelli), pope from 1185 to 1187, was by birth a Milanese, and was made cardinal and archbishop of Milan by Lucius III., whom he succeeded (25th November, 1185). He vigorously took up his prodecessor's quarrels with the emperor Frederick I., including the standing dispute about the succession to the territories of the countess Matilda. Even after his elevation to the popedom he continued to hold the archbishopric of Milan, and in this capacity refused to crown as king of Italy Frederick's son Henry, who had married Constantia, the heiress of the kingdom of Sicily. While Henry in the south cooperated with the rebel senate of Rome, Frederick in the north blocked the passes of the Alps and cut off all communication between the pope, then living in Verona, and his German adherents. Urban now resolved on excommunicating Frederick, but the

Veronese protested against such a proceeding being resorted to within their walls; he accordingly withdrew to Ferrara, but died (19th October) before he could give effect to his intention. His successor was Gregory VIII.

URBAN IV. (Jacques Pantaléon), pope from 1261 to 1264, was the son of a cobbler in Troyes, studied theology and common law in Paris, became bishop of Verdun, was employed in various missions by Innocent IV., and was made patriarch of Jerusalem by Alexander IV. He was at Viterbo seeking help for the oppressed Christians in the East when the last-named pope died, and after a three months' vacancy he was chosen to succeed him (29th August, 1261). As pope he endeavored, but without success, to stir up a new crusade on behalf of his former diocese of Jerusalem. In domestic matters the chief problems of his pontificate arose out of the competing claims for the crown of the Two Sicilies. Before the arrival of Charles of Anjou, the candidate whom he favored, Urban died at Perugia on 2d October, 1264. His successor was Clement IV. The festival of Corpus Christi was instituted by Urban IV. in 1264.

URBAN V. (Guillaume de Grimoard), pope from 1362 to 1370, was a native of Grisac in Languedoc. He became a Benedictine and a doctor in canon law, teaching at Montpellier and Avignon. He held the office of abbot of St. Victor in Marseilles; and at Avignon, on his way back from Naples, whither he had been sent as papal legate, he was elected pope (28th October, 1362) in succession to Innocent VI. As pope he was a severe disciplinarian, discountenanced the pomp and luxury of the cardinals, introduced considerable reforms in the administration of justice, and liberally patronized learning. His pontificate witnessed one of the last flickers of crusading zeal in the expedition of Peter of Lusignan, king of Cyprus, who took Alexandria (11th October, 1365), but soon afterwards abandoned it. The great feature of Urban V.'s reign was the effort to restore the papacy to Italy, and to suppress its powerful rivals for the temporal sovereignty there. In 1363 he excommunicated Bernabo Visconti, and ordered a crusade to be preached throughout Italy against him and his kindred, the robbers of the church's estate; but in the following year he found it necessary to purchase peace by removing his ban and making other humiliating concessions. Continued troubles in Italy caused him to set out for Rome, which he reached on 16th October, 1367; but, though he was greeted by the clergy and people with joy, and had the satisfaction of being attended by the emperor in St. Peter's and of placing the crown upon the head of the empress, it soon became clear that by changing the seat of his government he had not increased its power. Unable any longer to resist the urgency of the French cardinals, he took ship again at Corneto on 5th September, 1370, and, arriving at Avignon on the 24th of the same month, died on 19th December. He was succeeded by Gregory XI.

URBAN VI. (Bartolommeo Prignani), pope from 1378 to 1389, was a native of Naples, born in 1318. A devout monk and learned casuist, he became archbishop of Bari in 1377, and, on the death of Gregory XI., the Roman populace clamorously demanding an Italian pope, was unanimously chosen (8th April, 1378) by the French cardinals under this pressure to be his successor. The arrogant and imperious temper of the new pope, intoxicated by his unexpected fortune, showed itself in ways so intolerable that five months afterwards the majority of the cardinals met at Fondi, and, repudiating their previous action, proceeded to elect Robert of Geneva (20th September), who assumed the title of Clement VII. Thus began the great schism which divided Christendom for nearly forty years (see POPEDOM, vol. xix. p. 516). The measures of Urban were not without vigor, but at the same time were characterized by such a want of prudence and self-control as has given rise to the not improbable assertion that he actually was, at times at least, a lunatic. Clement VII. was, of course, excommunicated, and designated the Antichrist; twenty-six new cardinals were created in a single day, and, by an arbitrary alienation of the estates and property of the church, funds were raised for open war. The castle of St. Angelo was besieged and taken, and the antipope put to flight, while Charles of Durazzo was invested in the sovereignty of Naples, forfeited by Queen Joanna. In 1384, however, Charles began to resist the papal pretensions, and Urban was shut up in Nocera, from the walls of which he daily fulminated his anathemas against his besiegers; he afterwards succeeded in making his escape to Genoa, and, on the death of Charles, set himself at the head of his troops, apparently with the intention of seizing Naples for his nephew if not for himself. To raise funds he proclaimed a jubilee, though only thirty-three years had elapsed since that celebrated under Clement VI., but before the celebration he died at Rome of injuries caused by a fall from his mule, on 15th October, 1389. His successor was Boniface IX.

URBAN VII. (Giovanni Battista Castagna), pope for twelve days in September, 1590, was of Genoese origin, and was born in Rome in 1521. He was chosen successor of Sixtus V. on 15th September, 1590, but died (27th September) before consecration. He was succeeded by Gregory XIV.

URBAN VIII. (Maffeo Barberini), pope from 1623 to 1644, belonged to a Florentine family which had been greatly enriched by commerce, and was born in 1568. Through the influence of an uncle, who had become apostolic, protonotary, he, while still a young man, received various promotions from Sixtus V. and Gregory XIV. By Clement VIII. he was himself made protonotary and nuncio to the French court; Paul V. also employed him in a similar capacity, afterwards raising him to the cardinalate, and giving him the legation of Bologna. On 6th August, 1623, he was chosen successor to Gregory XV. The period of his pontificate, covering as it did twenty-one years of the Thirty Years' War, was an eventful one, and the ultimate result of that great struggle was largely determined by Urban's policy, which was aimed less at the restoration of Catholicism in Europe than at such an adjustment of the balance of parties as might best favor his own independence and strength as a temporal power in Italy (see POPEDOM, vol. xix. p. 520). In 1626 the duchy of Urbino was incorporated into the papal dominions, and in 1627, when the direct male line of the Gonzagas in Mantua became extinct, he favored the succession of the duke of Nevers against the claims of the Hapsburgs, whose preponderance he dreaded. He was the last pope to extend the papal territory, and Castelfranco on the Mantuan frontier was fortified by him. In Rome he greatly strengthened the castle of St. Angelo, removing, for the purpose of making cannons, the massive tubular girders of bronze from the portico of the Pantheon ("quod non fecerunt barbari, fecerunt Barberini"), establishing also an arsenal in the Vatican, as well as a manufactory of arms at Tivoli, and fortifying the harbor of Civita Vecchia. It was during the pontificate of Urban that Galileo was summoned to Rome to make his great recantation in 1633; on the other hand, the Poussins and Claude Lorraine were patronized by him, and it was he who brought Athanasius Kircher to Rome, and who employed Bernini to build the Palazzo Barberini, the college of the Propaganda, the Fontana del Tritone, and other prominent structures in the city. He was the last to practice nepotism on a grand scale; various members of his house were enormously enriched by him, so that it seemed to contemporaries as if he aimed at establishing a Barberini dynasty. He canonized many saints, among whom the most conspicuous are Ignatius Loyola, Francis Xavier, Al. Gonzaga, and Filippo Neri. Urban VIII. was a clever writer of Latin verse, and a collection of Scriptural para-phrases as well as original hymns of his composition has been frequently reprinted. His death (29th July, 1644) is said to have been hastened by chagrin at the result of a war he had undertaken against the duke of Parma. He was succeeded by Innocent X.

URBANA, a city of the United States, the county seat of Champaign county, Ohio. It lies 95 miles nearly N. N.E. of Cincinnati, in the midst of a rich agricultural region. It has railroad communication by means of three lines, the New York, Lake Erie, and Western, the Pittsburgh, Cincinnati, and St. Louis, and the Indiana, Bloomington, and Western. It has some manufactures, particularly of agricultural tools, machines, and railway rolling stock, and is the site of a Swedenborgian or New Church college. The population in 1880 was 6252, an increase of 46 per cent. since 1870. Urbana was laid out in 1805, when the county was organized.

URBINO, a mediæval walled city of Italy, on the site of the Roman *Urbinum Hortense*, in the Marches of Ancona, stands in a commanding position on a spur of the Tuscan Apennines, near the valley of the Metaurus, about 20 miles from the Adriatic. It grew up, chiefly in the 14th century, around the stronghold of the Montefeltro family. Federigo da Montefeltro, lord of Urbino from 1444 to 1482, was one of the most successful condottieri chiefs of his time, and not only a man of great military and political ability, but also an enthusiastic patron of art and literature, on which he lavished immense sums of money. Federigo much strengthened his position, first by his own marriage with Battista, one of the powerful Sforza family, and secondly by marrying his daughter to Giovanni della Rovere, the favorite nephew of Pope Sixtus IV., who in return conferred upon Federigo the title of duke. Federigo's only son Guidubaldo, who succeeded his father, married in 1489 a very gifted lady, Elizabeth Gonzaga, of the ruling family in Mantua. In 1497 he was expelled from Urbino by Cæsar Borgia, son of Alexander VI., but regained his dukedom in 1503, after Cæsar's death. Guidubaldo was the last duke of the Montefeltro line; at his death in 1508 he bequeathed his coronet to Francesco Maria della Rovere, nephew of Julius II., and for about a century Urbino was ruled by its second dynasty of the Della Rovere family. In 1626 the last descendant of Francesco, called Francesco Maria II., when old and childless abdicated in favor of Pope Urban VIII., after which time Urbino, with its subject towns of Pesaro, Fano, Fossombrone, Gubbio, Castel Durante, Cagli, and about 300 small villages, became part of the Papal States until the suppression of the temporal power in 1860.

During the reigns of Federigo and Guidubaldo, Urbino was one of the foremost centres of activity in art and literature in Italy, and was known as the Italian Athens. In 1468 Federigo gave orders to a Dalmatian architect, Luciano da Laurana, to build him a magnificent fortified palace; it was finished and enlarged by the Florentine Baccio Pintelli during Guidubaldo's reign. Rich friezes, sculptured architraves of doors and windows, and other decorations in marble, painting, and wood-work were executed by the sculptor Ambrogino di Milano, and by Francesco di Giorgio Martini of Siena (1439–1506), whom Vasari wrongly states to have been the principal architect of the palace. Federigo adorned his palace with fine series of paintings by Piero della Francesca, Melozzo da Forli, Paolo Uccello, and Raphael's father, Giovanni Santi; and, in addition to the crowd of able Italian artists whom he invited to his court, Flemish painters, such as Justus of Ghent, visited and worked in this hospitable city.[1] The rich wood-work in the palace, decorated with *tarsia*, or wood mosaic, was executed by Gondolo Tedesco; the rooms were filled with magnificent furniture, costly gold and silver plate, and works of art of all kinds. Literature was no less encouraged under the patronage of Federigo: it was at his court that Piero della Francesca wrote his celebrated work on the science of perspective, Francesco di Giorgio his *Trattato d' Architettura* (published by Saluzzo, Turin, 1841), and Giovanni Santi his poetical account of the chief artists of his time, among whom, probably from jealousy, he has omitted to mention either Justus of Ghent or Francesco di Giorgio, the latter a man of extraordinarily versatile talents, who was much employed by the duke to design fortifications and military engines, to paint wall decorations, and to carve sculptured ornaments.[2] Though stripped of its art treasures and dismantled of its decorations, the ducal palace still exists in a good state of preservation: it is a very picturesque, massive building of irregular plan, suited to its uneven site, and stands up very nobly on the hill, dominating all the rest of the city.[3] The refined magnificence of Guidubaldo's court is eloquently described by Baldassare CASTIGLIONE (*q.v.*) in his *Cortegiano*. When Henry VII. of England conferred the order of the Garter on Guidubaldo, Count Castiglione was sent to England with a letter of thanks and with the small picture, now in the Louvre, of St. George and the Dragon, painted by Raphael[4] in 1504, as a present to the English king.[5] This painting was among Charles I.'s collection which was sold by order of the Commonwealth in 1649.

Throughout the whole of the 16th century the state of Urbino was one of the chief centres for the production of majolica (see POTTERY, vol. xix. p. 646 *sq.*), especially the towns of Gubbio and Castel Durante. Most of the finest pieces of Urbino ware were made specially for the dukes, who covered their sideboards with the rich storied *piatti di pompa*, of which fine specimens have recently sold for from £2000 [$9720] to £3000 [$14,580].[6] Among the distinguished names which have been associated with Urbino are those of the Ferrarese painter and friend of Raphael, Timoteo della Vite, who spent most of his life there, and Bramante, the greatest architect of his age.[7] The Milanese sculptor, Ambrogino, who worked so much for Federigo, married a lady of Urbino, and was the progenitor of the Baroccio family, among whom were many able mathematicians and painters. Federigo Baroccio, Ambrogino's grandson, was a very popular painter, some of whose works still exist in the cathedral and elsewhere in Urbino. This city was also the birthplace of Pope Clement XI., of several cardinals of the Albano family, and of Bernardino Baldi, Fabretti, and other able scholars.

The modern city of Urbino, with a population of 5087 in 1880, is the seat of an archbishop, and still possesses a small university, but is not a thriving place. The cathedral, a building of no special interest, stands in the great piazza opposite the ducal palace, which is now used for municipal purposes and contains the city archives. In the sacristy there is a very beautiful miniature-like painting of the Scourging of Christ, by Piero della Francesca. One of the finest paintings by this artist is a large altar-piece of the Madonna enthroned between angels and saints, now in the Brera at Milan; it contains a very noble kneeling figure of Federigo in full armor, showing his strange profile disfigured by a bullet, which carried away part of the bridge of his nose. It was originally a votive retable given by the duke to the monastic church of San Bernardino, about a mile outside the walls of Urbino, where Federigo and Guidubaldo were buried. The modest house where Raphael was born and spent his boyhood is still preserved. It is now the property of a society of artists, and so is safe from destruction. Its rooms form a sort of museum of engravings and other records of Raphael's works, together with a picture of the Madonna by his father, Giovanni Santi, formerly thought to be by Raphael himself. The Institute of the Fine Arts in the Marches contains a small but interesting collection of pictures, including works by Giovanni Santi, Justus of Ghent, Timoteo della Vite, and other 15th-century artists. The picture of the Holy Communion by Justus is specially valuable from its containing fine portraits of the Montefeltro family and members of the ducal court. On the walls of the chapel of the guild or confraternity of San Giovanni are some valuable early frescos, painted by Lorenzo da San Severino and his brother, of the Florentine school, about 1416. An interesting collection of Roman inscriptions, arranged by the palæographer Fabretti, is still preserved on the upper walls of a court in the ducal palace. In the church of S. Spirito are two paintings by Luca Signorelli, the Crucifixion and the Day of Pentecost, originally intended for a processional banner. The theatre, decorated by Girolamo Genga, is one of the earliest in Italy; in it was performed the first Italian comedy,[1] the *Calandria* of Cardinal Bibbiena, the friend of Leo X. and Raphael. The magnificent library formed by the Montefeltro and Della Rovere dukes has been removed to Rome.

---

[1] The works of art from the palace of Urbino were scattered in the 17th century. Two paintings of the Sciences, part of a series executed for Federigo, are now in the National Gallery, London, where they are doubtfully attributed to Melozzo da Forli. Another by Justus of Ghent is in the royal collection at Windsor.

[2] The very high esteem felt for Francesco's personal character and genius by the duke is shown in a letter which Federigo wrote to the commune of Siena . see Ricci, *Storia d' Architettura*, vol. ii. p. 538. His life is given by Vasari, part i.

[3] See Arnold, *Der herzogliche Palast von Urbino*, Leipsic, 1857; and Baldi, *Descrizione del Palazzo Ducale di Urbino*, Rome, 1724.

[4] For Raphael's birth in Urbino, and his subsequent connection with that town, see RAPHAEL.

[5] [The Raphael of 1506 is the one referred to and is in L'Ermitage, St. Petersburg. The one in the Louvre is 1504 in date.—AM. ED.]

[6] The Bargello at Florence and the South Kensington Museum possess the finest collections of Urbino ware.

[7] Much information about Urbino and its crowd of artists is given by Pungileoni, *Elogio Storico di Giov. Santi*, Urbino, 1822.

In addition to works quoted above, see Dennistoun, *Memoirs of the Dukes of Urbino*, London, 1851; Card. di San Clemente, *Memorie concernenti la Città di Urbino*, Rome, 1724; and Sismondi, *Histoire des Républiques Italiennes*, Paris, 1807-8. An interesting view of Urbino, in the first half of the 16th century, occurs among the pen drawings in the MSS. *Arte del Vasajo*, by the potter Piccolpasso, now in the South Kensington Museum. (J. H. M.)

UREA is known chiefly as a component of urine. Referring to the article NUTRITION (vol. xvii. pp. 686–706) for its physiological relations, we consider it here only as a chemical substance. Urea, $CO(NH_2)_2$, was discovered by H. M. Rouelle in 1773; Fourcroy and Vauquelin in 1799 published the first exact investigation on it. In 1828 Wöhler showed that it can be obtained by the union in aqueous solutions of cyanic acid with ammonia, and thus for the first time effected what was then considered an impossibility, namely, the artificial preparation of an organic compound from mineral matter. For the extraction of urea from urine the latter is concentrated by evaporation (more or less, according to its original strength), and then, after cooling, mixed with a large excess of pure[2] nitric acid of 1.4 specific gravity. On standing in the cold most of the urea separates out as a crystalline nitrate, $CO . N_2H_4 . HNO_3$, which is collected over glass wool and washed with nitric acid. To convert it into urea it is treated with water and carbonate of baryta, which acts upon the HNO_3 as if it were present as such, the urea being liberated. The mixed solution of urea and the nitrate is evaporated to a small volume and allowed to stand, when the bulk of the barytic nitrate crystallizes out. The rest is removed by evaporating the mother liquor to dryness over a water-bath and extracting the urea with strong alcohol. To obtain fine crystals, the filtered alcoholic solution is evaporated to dryness, the residual urea dissolved in a very little hot water, and the solution allowed to cool slowly, when part of the urea crystallizes out in long colorless columns, not unlike those of nitrate of potash.

Wöhler's synthetical method for preparative purposes usually assumes the following form. Powdered prussiate of potash (see PRUSSIC ACID) is dehydrated by heating, the anhydrous salt mixed with half its weight of anhydrous binoxide of manganese, and the mixture heated in a flat iron pan until the deflagration, which soon sets in, is completed. The residue now consists of oxides of iron and manganese and of cyanate of potash, $NCO . K$, formed from the cyanide of potassium of the prussiate by oxidation. The cyanate of potash is extracted by means of the least sufficient quantity of cold water (hot water decomposes the salt, with the formation of ammonia and carbonate of potash), and the solution is mixed at once with the calculated weight of sulphate of ammonia, $1(NH_4)_2SO_4$ for $2NCO . K$. The two salts decompose each other into sulphate of potash and cyanate of ammonia; the latter, however, passes spontaneously and almost instantaneously into urea:

$$\underset{\text{Cyanate of ammonia.}}{NCO . NH_4} = \underset{\text{Urea.}}{CO(NH_2)_2}.$$

The sulphate of potash is eliminated exactly as the nitrate of baryta is in the urine method. That urea is not cyanate of ammonia itself is proved, first by the fact that real cyanate of ammonia (preparable by the union of anhydrous cyanic acid with ammonia gas) is a different substance, and secondly by its not yielding any ammonia when dissolved in cold caustic potash. Urea behaves to certain strong acids like a feeble basis, uniting (CON_2H_4 parts) with HNO_3 parts of nitric, $\frac{1}{2}H_2SO_4$ of sulphuric, and $\frac{1}{2}C_2O_4H_2$ of oxalic acid into crystalline salts. As shown by its formula, urea is the amide of carbonic acid: *i.e.*, it is $CO(OH)_2 - 2OH + 2NH_2$, and consequently an anhydride of carbonate of ammonia, $CO(O . NH_4)_2$. An aqueous solution of urea, when heated to 200° in a sealed-up tube, breaks up into carbonic acid and ammonia; and dry carbonate of ammonia, when kept at a certain temperature, suffers partial conversion into urea and water.

Of the many methods for the quantitative determination of the urea in urine, the simplest is to treat a measured volume with excess of solution of hypobromite of soda (a solution of bromine in caustic soda) and to measure the volume of nitrogen evolved. By theory $CON_2H_4 + 3NaBrO = 3NaBr + CO_2 + 2H_2O$ (the CO_2 is absorbed by the excess of alkali); but in practice, according to Dupré, through unknown causes only 91 per cent. of the nitrogen is actually evolved, which must be remembered in the calculation of the result.

URGA, a city of Mongolia and the administrative centre of the Northern and Eastern Khalkha tribes, is situated in 48° 20′ N. lat. and 107° 30′ E. long., on the Tola river. The Chinese and Mongolian towns which make up Huræ, as the Mongols call Urga, stand on the high road from Peking to Kiachta (Kiakhta), about 700 miles from the Chinese capital and 165 from Kiachta, and are separated from each other by an interval of 2 or 3 miles. The Chinese town is the great trading quarter, and there the wealth of the district is collected. The houses in this part are more substantially built than in the Mongol town, and the streets have a well-to-do appearance. The population is estimated at about 5000, and the law which prohibits Chinamen from bringing their wives and families into the place tends to check increase. The population of the Mongol quarter is reckoned at about 10,000, though on the occasions of the religious festivals the numbers are much larger. Although trade is not altogether excluded, the *raison d'être* of the town is that it is the residence of the metropolitan of the Khalkha tribes, who ranks third in degree of veneration among the dignitaries of the Lamaist Church. This "resplendently divine lama" resides in a sacred quarter on the western side of the town, and acts as the spiritual colleague of the Chinese lieutenant-general, who controls all mundane matters at Urga itself, and who is also especially charged with the control of the frontier town of Kiachta and the trade conducted there with the Russians. Until quite lately bricks of tea formed the only circulating medium for the retail trade at Urga, but Chinese brass cash are now beginning to pass current in the markets. The temples in the Mongol quarter are numerous and imposing in appearance, and in one is a gilt image of Maitreya Bodhisattva, 33 feet in height and weighing 125 tons. By the Chinese Urga is called K'ulun.

URI,[3] one of the Forest Cantons of Switzerland, ranks as fourth in the Confederation. It comprises

---

[1] [For first comedy played in Italy see vol. vii. p. 361.—AM. ED.]

[2] This word points chiefly to the absence of nitrous acid, which, if present, decomposes its equivalent of urea into nitrogen, water, and carbonic acid, thus:

$$\underset{\text{Urea.}}{CO(NH_2)_2} + \underset{\text{Nitrous acid.}}{2HO . NO} = \underset{\text{Carbonic acid.}}{CO(OH)_2} + \underset{\text{Nitrogen.}}{2N_2} + \underset{\text{Water.}}{2H_2O}.$$

[3] The name is probably connected with the same obscure root as Urseren and Reuss, and is popularly derived from *Urochs*, "wild bull," a bull's head having been for ages borne on the cantonal shield.

the upper basin of the Reuss from its source to the Lake of Lucerne, the southern arm of which is also within the canton. Its total area is 415.4 square miles; of these 184.4 are classed as productive, 40.3 are covered with forests, 44.3 consist of glaciers, and 7.7 of the lake. The highest point in the canton is the Galenstock (11,802 feet). The population in 1880 amounted to 23,694 (men having a majority of 3000 over women), showing an increase of 7649, or 39.4 per cent., since 1870, owing to the St. Gotthard Railway. German is the native tongue of 18,024 persons, Italian of 5313. The canton has always been very strongly Roman Catholic (23,149 in 1880). It was included up to 1814 in the diocese of Constance (except the valley of Urseren, which was in that of Chur), and since then has formed part of no diocese, but is provisionally administered by the bishop of Chur. In Uri the limits of the ecclesiastical parishes are the same as those of the civil communes. The capital is Altdorf (2901 inhabitants). Göschenen (2990) and Wasen (2744) have increased since the opening of the St. Gotthard Railway (1880), which runs through the greater part of the canton. The inhabitants are occupied in agricultural and pastoral pursuits, and are very saving and industrious. The main valley is fertile, but the side glens are very wild. Education is still very backward and largely in the hands of the priests; but an improvement was made in 1885. The main characteristics of the people are extreme conservatism and a passionate attachment to their religion.

Uri is first mentioned in history in 732 as the place to which Eto, abbot of Reichenau, was banished. For the early history of the canton, see SWITZERLAND, vol. xxii. pp. 820–4. In 1410 a perpetual alliance was made with the upper valley of Urseren or Val Orsera, the latter being allowed its own headman and assembly, and courts under those of Uri, with which it was not fully incorporated till 1803. In 1440 Uri alone won the Val Leventina for good, the title being confirmed by a treaty of 1466 with the duke of Milan and by the bloody fight of Giornico (1478). At the Reformation, Uri clung to the old faith (see SWITZERLAND, vol. xxii. pp. 830–1). In 1798 on the formation of the Helvetic republic Uri lost all its Italian possessions. In September, 1799, Suwaroff and the Russian army, having crossed the St. Gotthard to Altdorf, were forced by the French to pass over into Schwyz, instead of sailing down the lake to Lucerne. In 1803 Uri became an independent canton again, with Urseren, but without the Val Leventina. It tried hard to bring back the old state of things in 1814–15, and opposed all attempts at reform, joining the League of Sarnen in 1832 to maintain the pact of 1815, opposing the proposed revision of the pact, and being one of the members of the Sonderbund in 1843. Despite defeat in the war of 1847, Uri voted against the federal constitution of 1848, and by a crushing majority against that of 1874. The existing constitution of Uri is that framed in 1850 and amended in 1851, 1872, 1879, and 1881. The "landesgemeinde," composed of all male citizens of twenty years of age, meets annually on 1st Sunday in May, and is the supreme legislative assembly. There is a subordinate legislative assembly (landrath), consisting of the landammann or headman and his deputy, 4 of the members of the executive, and 70 elected members (1 for every 300 of the population), which drafts bills and passes laws provisionally in case of necessity. The executive consists of 9 members—the landammann, his deputy, and the treasurer, with 6 elected members. By an immemorial custom 7 men of 7 different families, bearing different names, can cause an extraordinary meeting of the assembly of their "gemeinde" to be summoned, or call on the landrath to do the same in the case of the "landesgemeinde."

See K. F. Lusser's *Gesch. des Kantons Uri* (1862).

URIC ACID, as explained fully in the article NUTRITION (vol. xvii. p. 702), is one of the penultimate products of the tissue waste in the human body. While the bulk of the nitrogen of the albuminoids passes off through the bladder as UREA (*q.v.*), a small portion of it stops at the uric acid stage. Human urine contains only a fraction of 1 per cent. of the acid, chiefly as soda salt; abundance of uric acid is met with in the excrement of serpents and birds, with whom it is the principal nitrogenous product of tissue waste. For the preparation of uric acid ($C_5H_4N_4O_3$), GUANO (*q.v.*) is boiled repeatedly with a solution of borax in 120 parts of water. The filtered solution is acidified with hydrochloric acid, when impure uric acid separates out as a brown precipitate, which is washed with cold water. For its purification it is dissolved in hot dilute caustic potash or soda lye, the solution filtered, and the filtrate saturated with carbonic acid. An almost insoluble acid urate of alkali separates out, which is collected on a filter, washed, and decomposed by adding it in instalments to hot dilute hydrochloric acid. Uric acid separates out as a white precipitate, which is filtered off, washed, and dried, to be re-purified by a repetition of the alkali process or otherwise. Pure uric acid forms a snow-white micro-crystalline powder, devoid of smell or taste, soluble in 1800 parts of boiling and in 14,000 parts of cold water, but insoluble in alcohol and in ether. When heated it suffers complete decomposition.

For its detection in urine, the urine is mixed with excess of hydrochloric acid, and allowed to stand, when the uric acid separates out, generally colored reddish by impurities. To identify the precipitate, it is dissolved in a few drops of nitric acid on a watch-glass, and the solution cautiously evaporated to dryness. The residue, if exposed to ammonia gas as it comes off from the stopper of a liquor ammoniæ bottle, assumes the intense purple color of "murexide."

Urates.—Uric acid dissolves in excess of caustic potash lye as dipotassic salt, $C_5H_2K_2N_4O_3$, soluble in 44 parts of cold water, with the formation of a strongly alkaline solution. On the saturation of the solution with carbonic acid one-half of the potash is eliminated as bicarbonate, and a neutral salt, $C_5H_3KN_4O_3$, comes down as a precipitate, soluble in 800 parts of cold water. Soda and the alkaline earths behave similarly. But more interesting than its salts are the numerous derivatives obtainable from it, chiefly by the action of oxidizing agents. Most of these were discovered and investigated by Liebig and Wöhler in a classical research published in 1838. From 1861 to 1863 Adolf Bäyer supplemented their work by important new discoveries. He showed that all those metamorphoses of uric acid fall in naturally with the assumption that the molecule of uric acid consists of two urea rests—(NH)(CO)(NH)—united each by its two nitrogen affinities with a tricarbon group, (C_3O), by carbon affinities of the latter. To give an example of the practical meaning of the theory,—if uric acid is oxidized cautiously with nitric acid, one of the urea rests by uniting with the 2H of an H_2O is split off as urea, while the rest unites with the oxygen of the H_2O and other $O + H_2O$ into alloxan,—

$$\underbrace{(HN)-(CO.C(OH)_2.CO)-(NH)}_{CO},$$

the ureid of mesoxalic acid, $HO-(CO.C(OH)_2.CO)-OH$. On the application of more energetic oxidizing agents, that one urea rest still survives, but the tricarbon nucleus burns down into C_2O_2, the radical of oxalic acid, with formation of parabanic acid,

$$\underbrace{(HN)-(C_2O_2)-(NH)}_{CO},$$

the ureid of oxalic acid, $HO(C_2O_2)OH$.

URINE. See UREA and URIC ACID; also NUTRITION, vol. xvii. p. 703.

URMIA, or URUMIAH, a town of Persia, in the province of Azerbijan (Adarbaijan), lies 112 miles southwest of Tabriz and 10 from the west side of Lake Urmia, in the midst of an extremely fertile, highly cultivated, and densely peopled plain. Within the enclosures, consisting of a wall and deep ditch that can be flooded, there is a mixed Mohammedan and Christian population of from 25,000 to 30,000, while the surrounding district is studded with over 300 populous villages. Some of the streets are broader than is usual in Oriental towns and several are traversed by running water; but, beyond a busy bazaar and two or three old mosques, there is nothing of any interest. The chief industries are weaving, dyeing, and especially tillage, abundant crops of rice, melons, cotton, and excellent tobacco being raised in the neighborhood. Urmia has for many years been the centre of an American mission, which has had considerable success, especially amongst the so-called "Chaldean" or Nestorian Christians. According to an old tradition, Urmia was the birthplace of Zoroaster.

The lake, which takes its name from the town, and which is also known as the Daria-cha, or "Little Sea," is a completely landlocked basin, filling a shallow depression at the east foot of the Kurdish Highlands, but still about 5000 feet above sea-level. It is 90 miles long north and south, 30 miles broad, and 250 round, with a total area of 1600 square miles, but a mean depth of not more than 10 or 12 feet (45 in the deepest part sounded by Monteith), so that the whole volume is at least six times less than that of the much smaller lake of Geneva. There are as many as fifty-six islands, grouped chiefly towards the south, the largest 5 miles by 2, the smallest mere rocks, and none permanently inhabited, although they are tilled or used for grazing horses and sheep in winter. Although fed by numerous streams, the lake is intensely saline, more so even than the Dead Sea, and is consequently inhabited by no fish or other aquatic fauna, except a peculiar species of small crustacean, which affords abundant food to numerous swans and other wild-fowl. The salt, which forms extensive incrustations some inches thick round about the shelving northeastern and southern shores, appears to be derived from Tertiary beds (Dr. E. Tietze), and the geological formation appears to resemble that of Lake Niris in southern Persia (Blanford). The whole lacustrine basin, including the farthest sources of its influents, has an area of about 20,000 square miles, and the flooded part stood formerly at a much higher level than at present, as is shown by the water marks on the encircling heights, and by the Shahi peninsula in the northeast, which at one time was certainly an island. In recent years the evaporation has on the whole balanced the inflow, although the lake is now said to be slightly rising, owing to the larger discharge from the Jaghatu and Tatau, which were formerly to a great extent absorbed in irrigating the southern Miandab plain. Near the Selmas river and at the village of Dihkergan in the southeast occur the famous "marble springs," yielding the pink, yellow, and white "marble of Tabriz," used for ornamenting many public buildings throughout western Asia.

URQUHART, or URCHARD,[1] SIR THOMAS (*c.* 1605-1660), one of the most original and raciest translators from any foreign language into English, was the son of Sir Thomas Urquhart of Cromarty, the representative of a very ancient family, and of Christian, daughter of the fourth Lord Elphinstone. His birth-year is uncertain, but it is guessed at 1605, and his birthplace was the old mansion-house of Cromarty. Not much is known of his youth, or indeed of any part of his life; but he was certainly well educated, travelled over Europe, succeeded to a considerable, though much embarrassed, inheritance, and got together a remarkable library, which, however, fell into the hands of his creditors. All his later life was disturbed by pecuniary and political difficulties. He was an enthusiastic Royalist; and, so far as religious matters went, his principles may be judged from his favorite signature, "C. P.," for Christianus Presbyteromastix. He took part in the "Trot of Turriff" in 1639, and was rewarded by being knighted on 7th April, 1641, by the king's own hand at Whitehall. He took occasion by this visit to London to see through the press his first work, a collection of *Epigrams* of no great merit. Four years later, in 1645, he produced a tract called *Trissotetras*, a treatise on logarithms adjusted to a kind of memoria technica, like that of the scholastic logic. In 1649 he was proclaimed a rebel and traitor at the Cross of Edinburgh; but this does not seem to have done him much harm, and, though he took part in the march to Worcester, and was there wounded and taken prisoner, his always embarrassed affairs do not seem to have been much worsened thereby. He published in rapid succession during 1652 and 1653 a series of tracts with quaint titles and quainter contents. *Pantochronochanon* (sic) is an almost unbelievable genealogy of the house of Urquhart up to Adam, with the names extemporized for the earlier ages in a kind of gibberish, which seems to be after the pattern of the giants and heathens in the *Amadis*. *Ecskubalauron*, supposed to be a treatise on the virtues of a jewel found in the streets of Worcester, is in reality a rather elaborate treatise on the virtues of the Scottish character, as shown in the Admirable Crichton and others. Finally, *Logopandecteision* handles the subject of a universal language. These original works of Urquhart's, as far as intrinsic literary merits go, are not of much account; but they show perhaps better than anything else that singular mixture of patriotism, generosity, shrewdness, humor, with prejudice, almost insane family pride, crotchet, pedantry, and apparent insensibility to some kinds of the ridiculous which was the dominant characteristic of a certain part of the Scottish nation, and which has furnished Sir Walter Scott with some of his most matchless studies and touches. The *Translation of Rabelais*, which Urquhart produced in 1653, is a very different work from the literary point of view, entering into and reproducing the author's spirit with wonderful success, and, though by no means technically faithful, far excelling in value all merely faithful versions. Next to nothing is known of Urquhart after its date; it is said that he sought a refuge, like other cavaliers, on the Continent, and died (1660) of a fit of laughing, brought on by joy at hearing of the Restoration.

His original *Works*, with such scanty particulars of his life as are known, and with reproductions of two original and curious frontispieces, which represent him as a handsome and dandified wearer of full cavalier costume, were published in a stately quarto volume by the Maitland Club (Edinburgh, 1834). The Rabelais has been repeatedly reprinted, and with Motteux's additions forms the substance of *Gargantua and Pantagruel* in Bohn's Extra Series.

URSINUS, ZACHARIAS (1534–1583), German theologian, and one of the authors of the *Heidelberg Catechism* (see vol. v. p. 191), was a native of Breslau, and became a disciple of Melanchthon at Wittenberg. He afterwards studied divinity at Geneva under Calvin and Hebrew at Paris under Mercier. In 1561 he was appointed professor in the Collegium Sapientiæ at Heidelberg, where in 1563 at the instance of the elector-palatine, Frederick III., he drew up the *Catechism* in co-operation with Kaspar Olevian. The death of the elector in 1576 led to the removal of Ursinus, who from 1578 till his death in 1583 occupied a professorial chair at Neustadt-an-der-Haardt. His *Works* were published in 1587–89, and a more complete edition by his son and two of his pupils, Pareus and Reuterus, in 1612.

URSULA, ST., and her companions, virgins and martyrs, are commemorated by the Roman Church on 21st October. The *Breviary* gives no legend; but in current works, such as Butler's *Lives of the Saints*, it is to the effect that "these holy martyrs seem . . . to have met a glorious death in defence of their virginity from the army of the Huns. . . . They came originally from Britain, and Ursula was the conductor and encourager of the holy troop." The scene of the martyrdom is placed near the lower Rhine.

The date has been assigned by different writers to 238, *c.* 283, and *c.* 451. The story, however, is unknown both to Jerome and to Gregory of Tours—and this though the latter gives a somewhat detailed description of the Cologne church dedicated to that Theban legion with which the tradition of the martyred virgins was very early associated. The story of their fate is not entered under 21st October in the martyrology of Bede (*ob. c.* 735), of Ado (*c.* 858), of Usuard (*ante* 877), Notker Balbulus (896), or Hrabanus Maurus (845); but a 9th-century life of St Cunibert (*ob.* 663) associates a prominent incident in the life of this saint with the basilica of the sacred virgins at Cologne (Surius, vi. 275, ed. 1575). Not only does Archbishop Wichfrid attest a grant to the church of the sacred virgins outside the walls of Cologne (in 927), but he was a large donor in his own person. Still earlier a Cologne martyrology, written, as Binterim plausibly urges, between 889 and 891, has the following entry under 21st October; "xi. virg. Ursule Sencie Gregorie Pinose Marthe Saule Britule Satnine Rabacie Saturie Paladie." Much shorter entries are found in two of the old martyrologies printed in Migne (cxxxviii. 1207, 1275). A more definite allusion to the legend may be found (*c.* 847) in Wandelbert's metrical martyrology (21st October):

---

[1] So spelt on the title page of his first work.

> "Tunc numerosa simul Rheni per littora fulgent
> Christi virgineis erecta tropæa maniplis
> Agrippinæ urbi, quaram furor impius olim
> Millia mactavit ductricibus inclyta sanctis."

The full legend first makes its appearance in a festival discourse (*sermo*) for 21st October, written, as internal evidence seems to show, between 731 and 839. This *sermo* does not mention St. Ursula, but makes Pinnosa or Vinnosa the leader of these spiritual "amazons," who, to avoid Maximian's persecution, left their island home of Britain, following their bridegroom Christ towards that East whence their faith had come a hundred years before. The concurrent traditions of Britain, Batavia (where many chapels still preserved their memory), and Cologne are called in evidence to prove the same origin. The legend was already very old and the festival "nobis omni tempore celeberrima"; but, as all written documents had disappeared since the burning of the early church erected over the sacred bones, the preacher could only appeal to the continuous and careful memory of the society to which he belonged (*nostrates*). Even in his time there were skeptics who pointed dubiously to the full-grown bones of "widows" and of men among the so-called virgin relics. But to *a priori* reasoners who mock at the notion of gathering so large a band of virgins in one place there was a triumphant answer ready: if Christ, while yet a man on earth, could summon "twelve legions of angels" to his aid, surely we could allow that a meagre band of "less than 12,000 virgins might follow the stainless lamb" in heaven. The author of the *sermo* pointedly rejects the two theories that connected the holy virgins with the Theban band and brought them as pilgrims from the East to the West; but he adds that even in his days there still existed an inscription in the church, showing how it had been restored from its foundations by a certain "Clematius, vir consularis, ex partibus Orientis."

Two or three centuries later the *Passio XI. MM. SS. Virginum*, based apparently on the revelations made to Helentrude, a nun of Heerse near Paderborn, gives a wonderful increase of detail. The narrative in its present form may date somewhere between 900 and 1100, while Helentrude apparently flourished before 1050. According to her account, the son of a powerful pagan king demands in marriage Ursula, the beautiful daughter of Deonotus, a king "in partibus Britanniæ." Ursula is warned by a dream to demand a respite of three years, during which time her companions are to be 11,000 virgins collected from both kingdoms. After vigorous exercise in all kinds of manly sports to the admiration of the populace, they are carried off by a sudden breeze in eleven triremes to Thiel in Guelderland on the Waal. Thence they sail up the Rhine by way of Cologne to Basel, at which place they make fast their vessels and proceed on foot to Rome. Returning they re-enter their ships at Basel, but are slaughtered by the Huns when they reach Cologne. Their relics are then collected and buried "sicut hodie illic est cernere," in a spot where "to this day" no meaner sepulture is permitted. Then follows the usual allusion to Clematius; the date is expressly fixed at 238; and the whole revelation is seemingly ascribed to St. Cordula, one of the eleven thousand, who, after escaping death on the first day by hiding in one of the vessels, on the morrow gave herself up to death of her own accord. Towards the beginning of the 12th century Sigebert of Gembloux (*ob.* 1112) gives a brief *résumé* of the same story. He is the first to introduce the name of Attila, and dates the occurrence 453.

Passing over the visions and exhumations of the first half of the 12th century, we come to the singular revelations of St. Elizabeth of Schönau. These revelations, delivered in Latin, German, or a mixed jargon of both languages, were turned into simple Latin by Elizabeth's brother Egbert, from whose words it would seem that in 1156 an old burial ground had lately been laid open near Cologne. The cemetery was naturally associated with the legend of St. Ursula; and, this identification once accepted, it is not unlikely that, when more careful investigation revealed male skeletons and tombstones bearing the names of men, other and more definite epitaphs were invented to reconcile the old traditions with the facts of such a damaging discovery. Hence perhaps the barefaced imposture: "Cyriacus, papa Romanus, qui cum gaudio suscepit sanctas virgines et cum eis Coloniam reversus martyrium suscepit." One or two circumstantial forgeries of this kind would form the basis of a scheme for explaining not a few other problems of the case, such as the plain inscription "Jacobus," whom St. Elizabeth promptly transformed into a supposititious British archbishop of Antioch, brother to the equally imaginary British Pope Cyriacus. For these epitaphs, with others of a humbler kind, were brought before St. Elizabeth to be identified in her ecstatic converse with St. Verena, her cousin St. Ursula, and others. Elizabeth herself at times distrusted her own revelations: there was no Cyriac in the list of the popes; Antherus, who was said to be his successor (235–236), died more than two centuries before Attila, to whom common report assigned the massacre, and it was hardly credible that James of Antioch could cut eleven thousand epitaphs in less than three days. Every doubt, however, was met by the invention of a new and still more improbable detail. According to St. Verena, the virgins suffered when Maximus and "Africanus" were *principes* at Rome (? 387–388).

In 1183 the mantle of St. Elizabeth fell upon Hermann Joseph, a Præmonstratensian canon at Steinfeld. He had to solve a more difficult problem than St. Elizabeth's; for the skeletons of little children, ranging in age from two months to seven years, had now been found buried with the sacred virgins. But even such a difficulty Hermann explains away as readily as he does the fact of his having changed St. Elizabeth's name for the royal bridegroom from Ætherius to Holofernes: the prince in question had two names, and the little children were brothers, sisters, or more distant relatives of the eleven thousand. Hermann's revelations are mainly taken up with an attempt to show the mutual relationship of nearly all the characters he introduces. The names are a most extraordinary mixture. Among British bishops we have Michael William, James, and Columbanus. Sovereign princes—an Oliver, a Clovis, and a Pippin—start out in every page, till the writer finds it necessary to apologize for the number of his kings and his own blunders. But, for all this, Hermann exposes his own doubts when he tells that often as he was preparing to write he heard a voice bidding him lay down the pen, "for whatever you write will be an unmixed lie." Hermann makes St. Ursula a native of Brittany, and so approximates to the version of the story given by Geoffrey of Monmouth (*Historia Britonum*), according to whom Maximian, after fleeing from Rome, and acquiring Britain by marriage, proceeds to conquer Brittany and settle it with men from the island opposite. For these settlers he has to find British wives, and to this end collects 11,000 noble and 60,000 plebeian virgins, who are wrecked on their passage across. Certain of the vessels being driven upon "barbarous islands," their passengers are slain by Guanius and Melga, "kings of the Huns and Picts," whom Gratian had called in to his aid against Maximian. In this version St. Ursula is a daughter of Dionotus, king of Cornwall. Hermann alludes more than once to the *Historia Britonum*, and even to King Arthur.

The legend of St. Ursula is perhaps the most curious instance of the development of an ecclesiastical myth. We know, however, too little about its earlier stages to justify any serious attempt at estimating what amount of historic truth underlies it, and it is doubtful whether many of the efforts in this direction do not make a larger demand on human credulity than the legend itself. Even in the earliest form known to us this legend is probably the complex growth of centuries, and any claim to the discovery of the first germ can hardly approve itself to the historic sense. These remarks apply especially to that venerable rationalization which evolves the whole legend from a misreading of *Undecimilla* into *undecim millia*. A more modern theory makes St. Ursula the Christianized representative of the old Teutonic goddess Freya, who, in Thuringia, under the name of Hörsel, welcomed the souls of dead maidens. Not a few singular coincidences seem to point in the same direction, especially the two virgins, "Martha and Saula," whom Usuard states to have suffered "cum aliis pluribus" on 20th October, whence they were probably transferred to 21st October. It is curious to note that Jerome and many of the earliest martyrologies extant have on 21st October the entry "Dasius Zoticus, Gaius *cum duodecim militibus*." Even in copies of Jerome this is transformed into *millibus*; and it is perhaps not impossible that to this misreading we may indirectly owe the "thousands" in the Ursula legend. So far as is known to the present writer, the two entries are mutually exclusive in all the early martyrologies mentioned in this article, and in those printed in Migne, cxxxvii. The earlier "Dasius" entry seems to disappear steadily, though slowly, as the Ursula legend works its way into current martyrologies.

See Crombach, *Vita et Martyrium S. Ursulæ*, Cologne, 1647, and the Bollandist *Acta Sanctorum*, 21st October. The rationalization of the story is to be found in Oscar Schade's *Die Sage von der heiligen Ursula*, Hanover, 1854, of which there is a short *résumé* in Baring-Gould's *Lives of the Saints*. Schade's results seem to be now generally accepted. (T. A. A.)

URSULINES, a religious order founded at Brescia by Angela Merici[1] in 1537, primarily for the education of girls. It was approved in 1544 by Paul III., and in 1572 Gregory XIII., at the instance of Charles Borromeo, made enclosure obligatory and declared it a religious order under the rule of St. Augustine. In the following century it was powerfully encouraged and supported by St. Francis de Sales; and towards the beginning of the 18th century, the period of its greatest prosperity, the order embraced some 20 congregations, with 350 convents and from 15,000 to 20,000 nuns. It still has some importance and possesses about 36 convents in Germany and Austria alone.[2]

URUGUAY. The republic of Uruguay, officially known as the ORIENTAL REPUBLIC OF THE URUGUAY, and long locally called the BANDA ORIENTAL (meaning the land on the eastern side of the large river from which the country takes its modern name), is the smallest independent state in South America. Plate I. Boundaries. It runs conterminous with the southern border of the empire of Brazil and lies between 30° and 35° S. lat. and 53° 25′ and 57° 42′ W. long.; its area is 73,185 square miles. The country is in some sense a peninsula, having a seaboard on the Atlantic Ocean of 120 miles, a shore line to the south on the river Plate of 235 miles, and another of 270 miles along the Uruguay on the west. The boundaries separating it from Rio Grande do Sul, a province of Brazil, are Lake Mirim, the rivers Chuy, Yaguaron, and Cuareim, and a *cuchilla* or low range of hills called Santa Ana. The extent of the northern frontier from the Cuareim to the bar of the Chuy on the coast of the Atlantic is 450 miles. Rivers. Uruguay is intersected nearly from west to northeast by the river Negro and its affluent the Yi. The Uruguay (see PLATE RIVER, vol. xix. p. 200) is navigable all the year by steamers from the island of Martin Garcia at the mouth to Salto (200 miles). Above this place the navigation is interrupted by rapids. The ordinary volume of water in the Uruguay averages 11 millions of cubic feet per minute. The Negro, of which the principal port is the city of Mercedes, is the only important and to any practical extent navigable inland river. Others are navigable for short distances and by steamers of light draught. Besides the rivers mentioned, the chief streams are the Santa Lucia, which falls into the Plate a little west of Montevideo; the Queguay in Paysandú; and the Cebollati, rising in the sierras in Minas and flowing into Lake Mirim. These rivers as well as the Uruguay are fed by innumerable smaller streams or "arroyos," many of which have the importance and sometimes the names of rivers, such as the Arapey in Salto, the Dayman in Paysandú, the Yaguary (an affluent of the Negro) in Tacuarembó, the Arroyo Grande between the departments of Soriano and San José, and the San José (an affluent of the Santa Lucia). Mountains. None of the sierras or mountains in Uruguay exceed (or perhaps even attain) a height of 2000 feet; but, contrasting in their tawny color with the grassy undulating plains, they loom up high and are often picturesque. They are ramifications of a range which, breaking away from the Andes in about 20° S. lat., reaches the frontier of Uruguay in 32°. Here the chain divides, forming the Cuchilla de Haedo on the north and west and the Cuchilla Grande on the south and east. In the departments of Minas and Maldonado the second range takes the name of the Ghost Mountains. No accurate geological survey has yet been made, but it is known that the hills in the north are chiefly gneiss and granite and in other parts porphyry and sandstone. The hilly districts in the north and east contain minerals of many kinds, including gold, lead, copper, agate, amethyst, alabaster, and marble. The limestone, granite, and marble quarries have some commercial value; but so far little progress has been made in the working of metallic veins. For the gold mines, see below.

The seat of government is the city of MONTEVIDEO (*q.v.*) at the entrance of the river Plate. The harbor and roadstead of that port form the only good natural refuge for shipping for hundreds of miles south of Rio de Janeiro.

Climate.

Uruguay has a healthy climate. Endemic diseases are unknown and epidemics are rare. According to the tables of mortality for 1882, out of a total of 9640 deaths 45 were of persons over 100 years of age. In the interior, away from the sea and the shores of the great rivers, the temperature frequently rises in summer as high as 86° Fahr. and in winter falls as low as 35.6° Fahr. In the districts bordering on the coast the thermometer seldom falls below 37°; and only for a few moments and at long intervals has it been known to rise as high as 105°. The annual rainfall is stated to be more than twice that of Paris (19.68 inches). This arises not from the frequency of rain but from the greater quantity which falls in a given time. Observations made during the years 1842 to 1852 inclusive showed that there were in Montevideo in the summer season —November, December, and January—70.1 fine days, 14.1 cloudy, and 6.1 wet; in winter—May, June, and July—there were 54.3 fine, 27.1 cloudy, and 10.6 wet days.

Flora.

The pastoral wealth of Uruguay as of the neighboring Argentine Republic is due to the fertilizing constituents of "pampa mud," geologically associated with gigantic antediluvian animals, whose fossil remains are found abundantly in those regions. The country is rich in hard woods, suitable for cabinet work and certain building purposes. The principal trees are the alder, aloe, palm, poplar, acacia, willow, and eucalyptus (recently introduced). The "montes," by which are understood plantations as well as native thickets, produce amongst other woods the algarrobo, a poor imitation of oak; the guayabo, a substitute for boxwood; the quebracho, of which the red kind is compared to sandalwood; and the urunday, black and white, not unlike rosewood. Indigenous palms grow in the valleys of the Sierra José Ignacio, also to some extent in the departments of Minas, Maldonado, and Paysandú. The myrtle, rosemary, mimosa, and the scarlet-flowered ceibo are amongst the plants commonly seen. The valleys within the hill ranges are fragrant with aromatic shrubs. In the plains below the swards are gay with the scarlet and white verbena and other wild flowers of brilliant hues. The country abounds in medicinal plants. The sarsaparilla even colors the water of the Rio Negro and gives to it its name—the "black river."

Fauna.

Amongst the wild animals the tiger or ounce—called in the Guaraní language the "ja-guá" or "big dog"—and the puma are found on the frontier of Brazil and on the wooded islets and banks of the larger rivers. The tapir, fox, deer, wild cat, wild dog, carpincho or water hog, and a few small rodents nearly complete the list of quadrupeds. A little armadillo, the mulita, must be mentioned as the living representative of the antediluvian giants, the mylodon, mastodon, megatherium, etc. The ostrich—*Rhea americana*—roams everywhere in the plains; and there are a few specimens of the vulture tribe, a native crow (lean, tall, and ruffed), partridges, and quails. Parakeets are plentiful in the "montes," and the lagoons swarm with waterfowl of all descriptions. The most esteemed is the "pato real," a large duck. Of the birds of bright plumage the humming bird and the cardinal—the scarlet, the yellow, and the white—are the most attractive. The fish of the lagoons and streams are coarse, and some of them primitive in type; but two or three kinds, found generally in the large rivers, are much prized. The varieties of fish on the sea coast are many and excellent; 130 species are known. More than 2000 species of insects have been classified. The scorpion is rarely seen; but large and venomous spiders are common. The principal reptiles are a lizard, a tortoise, the "vivora de la cruz," a dangerous viper, so called from marks like a cross on its head, and the rattlesnake, this last in Maldonado and the stony lands of Las Minas.

Population.

At the commencement of the 19th century the population of Montevideo and the surrounding territory was estimated by Azara at 30,000, one-half of these being given to the city of Montevideo. This total seems not to have included what remained of the indigenous inhabitants in the north and west, though the Indian population of the Jesuit missions before these were destroyed, about the year 1767, was known to be very numerous. But the aborigines have now completely disappeared. They have been supplanted by half-breeds, from whom the class known as gauchos are mostly recruited. The gauchos are now being supplanted by European immigrants and their progeny. In 1829, the epoch of the declaration of independence, the population is stated to have numbered 74,000, and in 1852, after the great war, 131,969. In 1860 the number had risen to 221,300 and in 1873 to 450,000. Comparatively recent estimates place it between 450,000 and 700,000, the latest official estimate being 551,768; but no formal census has yet been taken. In the eighteen[1] departments of the state the proportion of foreigners is 25.41 per cent. of the population (in the department of Montevideo 42.29 per cent. and in the others 24.66 per cent.), consisting of 39,780 Spaniards, 36,303 Italians, 20,178 Brazilians, 15,546 Argentinians, 14,375 French (principally Basques), 2772 English, 2125 Germans, and 9143 of other nations. The density of the population in the metropolitan department is 365 inhabitants per square mile; in the whole republic it is 4.83, in the agricultural department of Canelones 27.37, and in the remote departments of Tacuarembó and Rivera about 1.6. In respect of numbers the males have a slight preponderance over the females. Of the children 20.23 per cent. are illegitimate, in the metropolitan department 7.73 and in the rural departments 23.24. Illegitimate births have recently decreased, a fact which may be explained by the institution of civil marriage and by the appointment of registrars in the remote country districts. Marriages take place at the rate of 6.8 per 1000. The death-rate is only 16.5 per 1000.

---

[1] Born 1470, died 1540, canonized 1807.

[2] [A convent of this order in Charlestown, Mass., was burned in 1834 by a fanatical mob, irritated by unfounded reports of its harsh discipline. There are several foundations in North America.—AM. ED.]

Administrative divisions.

The country is divided into eighteen[1] departments, of which that of Montevideo is the smallest, although it contains one-fourth of the total population. Adjoining this is Canelones; and in a northerly direction are those of Florida, Durazno, Tacuarembó, and Rivera, the last-named bordering on Brazil. To the eastward on the Atlantic are Maldonado and Rocha, and north and west of these Minas, Treinta y Tres, and Cerro Largo. To the west, along the Plate and Uruguay, are San José, Colonia, Soriano, Rio Negro, and Paysandú; and farther north towards the Brazilian frontier are Salto and Artigas. The principal inland town is San José. The chief ports, besides Montevideo, are Salto, Paysandú, Fray Bentos, Mercedes, Colonia, and Maldonado.

Agriculture and industry.

More than two centuries ago the Banda Oriental was looked upon by the Spanish colonies on the opposite banks of the Plate and Uruguay as a station for the breeding of live stock and the cutting of timber and firewood. And at this day, in spite of the thriving foreign trade of Montevideo, it still partakes largely of this character. It boasts of 20,000,000 sheep—perhaps 14,000,000 would be nearer the mark—and 8,000,000 head of cattle. The country being in general pastoral, sheep and cattle grazing is the main occupation of the people; the sheep flourish best in the southern and western departments, whilst the principal cattle districts are towards the north and east. More than two-thirds of the public wealth, estimated variously between £80,000,000 [$388,800,000] and £120,000,000 [$583,000,000], consist of land, live stock, and rural properties. Ninety-six per cent. of the exports of the country consist of live stock and their produce—wool, hides, horns, hair, sheepskins, tallow, grease, bones, bone-ash, and jerked beef. More than half the fixed property and commercial capital is in the hands of foreigners. At Fray Bentos, in the department of Rio Negro, is the Liebig factory of extract of meat; at Colonia there is a branch of the River Plate Frozen Meat Company. But, apart from these, and some breweries, flour-mills, tanneries, establishments in Montevideo for the making of boots and shoes and clothing, and a few local industries, unnaturally fostered by high import duties, there are no manufactures to speak of. Agriculture is still in a promising infancy. Latterly it has made great strides; yet the export of agricultural produce appears to be relatively insignificant. At intervals during the last twenty years agricultural settlements (colonies) have been established with great success in different departments, but principally in Colonia, where the settlers are mostly Italians and Swiss. These prosperous colonies have already in Colonia outgrown the space originally allotted; but owing to the irregular and illegal appropriation of the public lands there is no more land to bestow on settlers, native or foreign, except at the exorbitant rates demanded by private owners and speculators.

Minerals.

At Cuñapirú in Tacuarembó gold was accidentally discovered in 1842. The mines have been worked at intervals since 1867, but, partly owing to difficulties of communication, with indifferent success. But gold-mining seems to have lately assumed a more hopeful aspect, owing to the employment of improved and economical machinery introduced by a French company. The metals of Uruguay are found in two quite distinct systems of hills. The Cuñapirú mines are in the Santa Ana range, the auriferous quartz being found in thin layers embedded in rocks of red porphyry. The formation of the system in general resembles that of the gold-producing regions in Brazil, California, and Australia. The Pan de Azucar Sugar-Loaf Mountain), near the south coast of Maldonado, forms the extremity of a second system, which has its origin as far north as Pernambuco in Brazil; as developed in Uruguay it is Huronian, limestone and slate being superposed on the gneiss and granite. The metals of this system are principally silver, lead, copper, and an argentiferous lead, which in earlier times the Spaniards mistook for silver. Two copper mines at the foot of the Pan de Azucar are now in active operation.

Commerce.

Since the beginning of the 19th century the value of the exports and imports has increased twenty-fold, and with some relapses has more than doubled in the last twenty years. In 1881 the total value was £8,116,680 [$39,447,064.80], and in 1885 £10,750,747 [$52,248,630.42.] The value of the exports is always a little in excess of that of the imports. Within the last ten years the number of vessels entering the port of Montevideo has increased only about 10 per cent., whereas the total tonnage has increased 100 per cent., owing to the large ocean steamers which trade with the port or make it a place of call. A few years ago the imports from Great Britain amounted to about a third of the whole, and the exports to the same country to about one-fourth of the whole. But much of the produce from the river Plate countries in general which formerly was shipped to England or to Antwerp now goes direct to France or to Hamburg and Bremen.

Communication.

Telegraph lines, with a total length of 661 miles, exist in most of the departments. Submarine cables communicate with Buenos Ayres and the ports of Brazil, and thence with Europe. The railways are comprehended in three main systems, the central, northwestern, and eastern; their combined length barely reaches 300 miles. There are no public roads in the country; but communication in the more inhabited parts is easily effected over the nearly level grassy plains.

Education.

The system of national education is gratuitous and compulsory. The number of school children is over 30,000, about 5.4 per cent. of the total population. The teaching at the national schools is irrespective of religious creed or denomination. In higher education much has yet to be accomplished. There is a school of arts and trades in the capital. The university of Montevideo, founded in 1838, numbers about 1300 students. The state religion is Roman Catholic; but all sects enjoy complete toleration, unless a decided non-toleration of the Jesuits be regarded as an exception to the rule.

Government.

The legislative power of the state rests with the general assembly, consisting of two chambers, one of senators (18) and one of representatives (51). The deputies of the lower house are elected annually and directly by the people, one deputy for every 3000 of the population, or any fraction not less than 2000. One senator is named for each department. The executive power is exercised by the president of the republic, who is elected by the general assembly. The judicial power is vested in a superior court, composed of two courts of appeal, which temporarily supply the place of a supreme court of justice, not yet created.

Army and navy.

The permanent army on a peace footing consists of 3323 men. The national guard numbers about 20,000. On an emergency the Government could put into the field 30,000 men. The regular troops are well armed and accoutred after the European fashion. The navy consists of a few small steamers and gunboats.

Finance.

The estimated revenue for 1886-87 was £2,775,362 [$13,488,259.32] (about two-thirds from custom dues, the rest from taxes on property and from stamps, trade licenses, etc.). Of the estimated expenditure about two-fifths are devoted to the payment of the interest on the public debt, which in 1883 amounted to £11,127,000 [$54,077,220]. On 1st July, 1886, the debt was officially stated to be £14,718,089 [$71,529,912.54].

History.

The history of Uruguay dates from 1512, when Juan Diaz de Solis entered the Paraná-guazú or "sea-like" estuary of the Plate and landed about 70 miles east of the present city of Montevideo. Uruguay at that time was inhabited by Indians, of whom the dominant tribe was called Charrúas, a people described as physically strong and well-formed, and endowed with a natural nobility of character. Their habits were simple, and they were disfigured neither by the worst crimes nor by the primitive superstitions of savages. They are said to have revealed no vestiges of religion. The Charrúas are generally classified as a yellow-skinned race, of the same family as the Pampa Indians; but they are also represented as tanned almost black by the sun and air, without any admixture of red or yellow in their complexions. Almost beardless, and with thin eyebrows, they had on their heads thick, black, lustrous hair, which neither fell off nor turned gray until the possessors reached the age of eighty. They lived principally upon fish, venison, and honey. In the Guarani language "Charrúa" means turbulent, and by their enemies the Charrúas were accounted as such, and even ferocious, although admitted to be generous to their captives. They were a curiously taciturn and reticent race. Their weapons were the bow and arrow and stones.

---

[1] [Flores, a recently formed department, with Trinidad for its chief city, brings the number up to nineteen.—AM. ED.]

Solis, on his second visit, 1515–16, was slain by the Charrúas in Colonia. Eleven years later Ramon, the lieutenant of Sebastian Cabot, was defeated by the same tribe. In 1603 they destroyed in a pitched battle a veteran force of Spaniards under Saavedra. During the next fifty years three unsuccessful attempts were made by the Spaniards to subdue this courageous people. The real conquest of Uruguay was commenced under Philip III. by the Jesuit missions. It was gradually consummated by the military and commercial settlements of the Portuguese, and subsequently by the Spaniards, who established themselves formally in Montevideo under General Zavala in 1729, and finally demolished the rival Portuguese settlement in Colonia in 1777. From 1750 Montevideo enjoyed a provincial government independent of that of Buenos Ayres. The American Revolution, the French Revolution, and the British invasions of Montevideo and Buenos Ayres (1806–7) under Generals Auchmuty and Whitelock all contributed to the final extinction of the Spanish power on the River Plate. During the war of independence Montevideo was taken in 1814 by the Buenos-Ayrean general Alvear. A long struggle for dominion in Uruguay between Brazil and the revolutionary Government of Buenos Ayres was concluded in 1828, through the mediation of Great Britain, Uruguay being declared a free and independent state. The republic was formally constituted in 1830. Subsequently Juan Manuel Rosas, dictator of Buenos Ayres, interfered in the intestine quarrels of Uruguay; and Montevideo was besieged by his forces, allied with the native partisans of General Oribe, for nine years (1842–51). From the era of its independence to about 1870 the history of Uruguay is a long record of foreign invasions and intrigues, financial ruin, and political folly and crime.

URUMIAH. See URMIA.

USBEGS. See BOKHARA, KHIVA, MONGOLS, TURKESTAN, and TURKS.

USHANT (Fr. *Ouessant*), the most westerly of the islands off the coast of France, 26 miles west-north-west from Brest, belongs administratively to the department of Finistère. It is about 4½ miles in length, and almost entirely granitic, with steep and rugged coasts, accessible only at a few points. The island affords pasturage to a few sheep and horses, and contains some small villages, the chief being St. Michel. The inhabitants are principally pilots and fishermen. The total population in 1886 was 2307.

USHER, JAMES (1580–1656), prelate and scholar, was born in the parish of St. Nicholas, Dublin, on 4th January, 1580. He was the eldest son of Arnold Usher, one of the six clerks in Chancery, and descended from the house of Nevill, one of whose scions, accompanying John Plantagenet to Ireland in the capacity of usher in 1185, adopted his official title as a surname. James Usher was sent to a school in Dublin opened by two political agents of James VI. of Scotland, who adopted this manner of averting the suspicions of Elizabeth's Government from their real object, which was to secure a party for James in Ireland in the event of the queen's death. In 1593 Usher matriculated as one of the first students at the newly-founded university of Dublin, whose charter had been obtained in 1592 by his uncle Henry Usher, archbishop of Armagh. He proved a diligent student, devoting much attention to controversial theology, graduated as M.A. in 1600, and became a fellow of Trinity College. On the death of his father in 1598 he resigned the family estate to his younger brother, reserving only a small rent-charge upon it for his own maintenance, and prepared to enter into holy orders. When he was but nineteen he accepted a challenge put forth by Henry Fitzsimons, a learned Jesuit, then a prisoner in Dublin, inviting discussion of Bellarmine's arguments in defence of Roman Catholicism, and acquitted himself with much distinction. In 1600 he was appointed proctor of his college and catechetical lecturer in the university, though still a layman, and was ordained deacon and priest on the same day, in 1601, while still under the canonical age, by his uncle the primate. In 1607 he became regius professor of divinity and also chancellor of St. Patrick's cathedral, Dublin. He was a frequent visitor to England to purchase books for his college library, and upon similar errands, making on these occasions the acquaintance of the most eminent scholars in London, Oxford and Cambridge, such as Camden, Selden, Sir Thomas Bodley, and Sir Robert Cotton. He took his degree of D.D. in 1612, and in the following year published his first printed work, though not his first literary composition.—*Gravissimæ Quæstionis de Christianarum Ecclesiarum, in Occidentis præsertim partibus, ab Apostolicis temporibus ad nostram usque ætatem, continua successione et statu, Historica Explicatio*, wherein he took up the history of the Western Church from the point where Jewel had left off in his *Apology for the Church of England*, and carried it on from the 6th till past the middle of the 13th century, but never completed it. In this same year he married Phœbe, daughter of Dr. Luke Chaloner, a wealthy heiress. In 1615 he took part in an attempt of the Irish clergy to impose a Calvinistic confession, embodying the Lambeth Articles of 1595, upon the Irish Church, and was delated to King James in consequence. But on his next visit to England in 1619 he brought with him an attestation to his orthodoxy and high professional standing, signed by the lord deputy and the members of the privy council, which, together with his own demeanor in a private conference with the king, so influenced the latter that he nominated Usher to the vacant see of Meath, of which he was consecrated bishop in 1620. In 1622 he published a controversial *Discourse of the Religion anciently professed by the Irish and British*, designed to show that they were in agreement with the Church of England and opposed to the Church of Rome on the points in debate between those churches. In 1623 he was made a privy councillor for Ireland, and in the same year was summoned to England by the king that he might more readily carry on a work he had already begun upon the antiquity of the British churches. While he was detained on this business the archbishop of Armagh died in January, 1624, and the king at once nominated Usher to the vacant primacy; but severe illness and other causes impeded his return to Ireland until August, 1626.

For many years Archbishop Usher was actively employed both in the government of his diocese and in the publication of several learned works, amongst which may be specified *Emmanuel* (a treatise upon the Incarnation), published in 1638, and *Britannicarum Ecclesiarum Antiquitates*, in 1639. In 1634 he took part in the convocation which drafted the code of canons that formed the basis of Irish ecclesiastical law till the disestablishment of the Irish Church in 1869, and defeated the attempt of Bramhall, then bishop of Derry and later his own successor in Armagh, to conform the Irish Church exactly to the doctrinal standards of the English. He put the matter on the ground of preserving the independence of the Irish Church, but the real motive at work was to maintain the Calvinistic element introduced in 1615. In 1640 he paid another visit to England on one of his usual scholarly errands, meaning to return when it was accomplished. But the rebellion of 1641 broke out while he was still at Oxford, and he never saw his native country again. He published a collection of tracts at Oxford in that year, inclusive of a defence of Episcopacy and of the doctrine of non-resistance. One blot on his memory is that, being one of the five prelates whom Charles I. consulted whether he could conscientiously assent to the Act of attainder against the earl of Strafford after having pledged his word to him for his safety, Usher joined in the casuistical advice given by all except Juxon, who alone told the king that his pledged word could not be lawfully broken. All Usher's property in Ireland was lost to him through the rebellion, except his books and some plate and furniture, but he was assigned the temporalities of the vacant see of Carlisle for his support. In 1643 he was offered a seat in the Assembly of Divines at Westminster, but declined it publicly in terms which drew upon him the anger of the House of Commons, and an order for the confiscation of his library was averted only by the interposition of Selden. He quitted Oxford in 1645 and went into Wales, where he remained till 1646, when he returned to London, and was in 1647 elected preacher to the Society of Lincoln's Inn, an office he continued to hold till a little before his death. During his residence in Wales a hyper-Calvinistic work entitled *A Body of Divinity; or the Sum and Substance of the Christian Religion*, was published under his name by Downham; and, though he repudiated the authorship in a letter to the editor, stating that the manuscript from which it was printed was merely a commonplace-book into which he had transcribed the opinions of Cartwright and other English divines, often disapproving of them and finding them dissonant from his own judgment, yet it has been persistently cited ever since as Usher's genuine work, and as lending his authority to positions which he had long abandoned, if he ever maintained them. In 1648 he had a conference with Charles I. in the Isle of Wight, assisting him in the abortive negotiations with Parliament on the question of Episcopacy. In 1650–54 he published the work which at the time and for more than a century afterwards was accounted his most important production, the *Annales Veteris et Novi Testamenti*, in which he propounded a scheme of Biblical chronology which held its ground until disproved by very recent advances in scholarship, and whose dates were inserted by some unknown authority in the margin of reference editions of the authorized version. He was to some extent favored by Cromwell after he became lord protector, who seems to have promised Usher a pension and a grant for twenty-one years of the lands belonging to the see of Armagh; but there is no proof that either was actually carried out. In 1655 Usher published his last work, *De Græca LXX. Interpretum Versione Syntagma.* He died on 20th March, 1656, in Lady Peterborough's house at Reigate in Surrey. His body was buried in Westminster abbey, in the chapel of St. Erasmus. To one daughter who survived him he left his library, and she sold it to the officers and soldiers of Cromwell's army in Ireland, who deposited it in Dublin castle, whence it was removed at the Restoration and given, according to Usher's original purpose, by direction of Charles II. to the library of Trinity College, of which it still forms a part.

Usher's works are very numerous, and were first collected by Elrington and Todd, Dublin, 1841–8, in 17 vols.

(R. F. L.)

USKUP, Uskub, or Skoplie, a town of European Turkey, capital of the sanjak of the same name and of the vilayet of Kossova, on the upper Vardar river, about 160 miles northwest of Saloniki. It occupies a picturesque and important strategic position near the southern foot of the Skhar-dagh (Scodrus), which connects the Balkan range in the east with the Bosnian and Albanian highlands in the west, and forms the water-parting between the streams flowing north to the Danube and those going south to the Ægean. Here also converge the ethnological domains of the Albanians and Slavs (Servians, Bosnians, and Bulgarians), so that the population, estimated at 28,000, is of a somewhat mixed character. Uskup has some flourishing industries, such as leather and metal-work, weaving and dyeing, and is the centre of a rich agricultural district growing large quantities of fruits and cereals. It is the residence of the provincial governor, the seat of a Greek archbishop, and one of the chief stations on the main line of railway which runs from Saloniki up the Vardar valley to Bosnia. It communicates with the Simnitza valley and with Prisren by practicable roads running north and northwest over the encircling ranges.

Uskup retains in a slightly modified form the ancient name of Skupi (Skopi), a city of Pæonia (north Macedonia), forming a northern outpost of Greek and Roman culture towards Dardania and Dacia Aureliani.

USURY. An ancient legal conception, it has been said, corresponds not to one but to several modern conceptions; and the proposition is equally true when economic is substituted for legal. Until quite recent times the term "usury" covered a number of essentially different social phenomena. "Thou shalt not lend upon usury to thy brother, usury of money, usury of victuals, usury of anything that is lent upon usury. Unto a stranger thou mayest lend upon usury; but unto thy brother thou shalt not lend upon usury, that the Lord thy God may bless thee" (Deut. xxiii. 19, 20). In this sentence we find interest of all kinds blended together, and the natural economic tendencies directly counteracted by the moral and religious law. At the present day, "usury," if used in the old sense of the term, would embrace a multitude of modes of receiving interest upon capital to which not the slightest moral taint is attached. The man who does not in some shape or other lend his capital upon "usury" is, in the modern world, generally considered as lacking in his duty to himself or his family. The change in the moral attitude towards usury is perhaps best expressed by saying that in ancient times so much of the lending at interest was associated with cruelty and hardship that all lending was branded as immoral (or all interest was usury in the moral sense), whilst at present so little lending takes place, comparatively, except on commercial principles, that all lending is regarded as free from an immoral taint. This change in the attitude of common-sense morality in respect to "anything that is lent upon usury" is one of the most peculiar and instructive features in the economic progress of society.

"It is worthy of remark," says Grote (*History of Greece*, vol. iii. p. 144), that the first borrowers must have been for the most part men driven to this necessity by the pressure of want and contracting debt as a desperate resource without any fair prospect of ability to pay; debt and famine run together in the mind of the poet Hesiod. The borrower is in this unhappy state rather a distressed man soliciting aid than a solvent man capable of making and fulfilling a contract; and if he cannot find a friend to make a free gift to him in the former character he would not under the latter character obtain a loan from a stranger except by the promise of exorbitant interest and by the fullest eventual power over his person which he is in a position to grant." This remark, though suggested by the state of society in ancient Greece, is largely applicable throughout the world until the close of the early Middle Ages. Borrowers were not induced to borrow as a rule with the view of employing the capital so obtained at a greater profit, but they were compelled of necessity to borrow as a last resort. The conditions of ancient usury find a graphic illustration in the account of the building of the second temple at Jerusalem (Neh. v. 1–12). The reasons for borrowing are famine and tribute. Some said, "We have mortgaged our lands, vineyards and houses, that we might buy corn, because of the dearth;" others said, "We have borrowed money for the king's tribute, and that upon our lands and vineyards . . . and, lo, we bring into bondage our sons and our daughters to be servants, . . . neither is it in our power to redeem them, for other men have our lands and vineyards." In ancient Greece we find similar examples of the evil effects of usury, and a law of bankruptcy resting on slavery. In Athens about the time of Solon's legislation (594 B.C.) the bulk of the population, who had originally been small proprietors or metayers, became gradually indebted to the rich to such an extent that they were practically slaves. Those who still kept their property nominally were in the position of Irish cottiers: they owed more than they could pay, and stone pillars erected on their land showed the amount of the debts and the names of the lenders. Usury had given all the power of the state to a small plutocracy. The remedy which Solon adopted was of a kind that we are accustomed to consider as purely modern. In the first place, it is true that according to ancient practice he proclaimed a general *seisachtheia*, or shaking off of burdens: he cancelled all the debts made on the security of the land or the person of the debtor. This measure alone would, however, have been of little service, had he not at the same time enacted that henceforth no loans could be made on the bodily security of the dèbtor, and the creditor was confined to a share of the property. The consequence of this simple but effective reform was that Athens was never again disturbed by the agitation of insolvent debtors. Solon left the rate of interest to be determined by free contract, and sometimes the rate was exceedingly high, but none of the evils so generally prevalent in antiquity were experienced.

When we turn to Rome, we find exactly the same difficulties arising, but they were never successfully met. As in Athens in early times, the mass of the people were yeomen, living on their own small estates, and in time they became hopelessly in debt. Accordingly the legislation of the XII. Tables, about 500 B.C., was intended to strike at the evil by providing a maximum rate of interest. Unfortunately, however, no alteration was made in the law of debt, and the attempt to regulate the rate of interest utterly failed. In the course of two or three centuries the small free farmers were utterly destroyed. By the pressure of war and taxes they were all driven into debt, and debt ended practically, if not technically, in slavery. It would be difficult to over-estimate the importance of the influence of usury on the social and economic history of the Roman republic. In the provinces the evils of the system reached a much greater height. In 84 B.C. the war tax imposed by Sulla on the province of Asia was at first advanced by Roman capitalists, and rose within fourteen years to six times its original amount. It is interesting to observe that the old law of debt was not really abolished until the dictatorship of Julius Cæsar, who practically adopted the legislation of Solon more than five centuries before; but it was too late then to save the middle class. About this time the rate of interest on first-class security in the city of Rome was only about 4 per cent., whilst in the provinces from 25 to 50 per cent. were rates often exacted. Justinian made the accumulation of arrears (*anatocismus*) illegal and fixed the rate at 6 per cent., except for mercantile loans, in which the rate received was 8 per cent. On the whole it was truly said of usury during the republic and early years of the empire: "Sed vetus urbi fenebre malum et seditionum discordiarumque creberrima causa." Even when it came to be authorized by Roman law under certain restrictions, it was still looked upon as a pernicious crime. "Cicero mentions that Cato, being asked what he thought of usury, made no other answer to the question than by asking the person who spoke to him what he thought of murder."

It was only natural, considering the evils produced by usury in ancient Greece and Rome, that philosophers should have tried to give an *a priori* explanation of these abuses. The opinion of Aristotle on the barrenness of money became proverbial, and was quoted with approval throughout the Middle Ages. This condemnation by the moralists was enforced by the fathers of the church on the conversion of the empire to Christianity. They held usury up to detestation, and practically made no distinction between interest on equitable moderate terms and what we now term usurious exactions.[1] The consequence of the condemnation of usury by the church was to throw all the dealing in money in the early Middle Ages into the hands of the Jews. A full account of the mode in which this traffic was conducted in England is given by Madox in chapter vii. of his *History of the Exchequer* (London, 1711). The Jews were considered as deriving all their privileges from the hand of the king, and every privilege was dearly bought. There can be no doubt that they were subjected to most arbitrary exactions. At the same time, however, their dealings were nominally under the supervision of the Jews' exchequer, and a number of regulations were enforced, partly with the view of protecting borrowers and partly that the king might know how much his Jews could afford to pay. It was probably mainly on account of his money-lending that the Jews were so heartily detested and liable to such gross ill-treatment by the people. A curious illustration of this popular animosity is found in the insertion of a clause in the charters granted by Henry III. to Newcastle and Derby, forbidding any Jew to reside in either place. Ultimately in 1290 the Jews were expelled in a body from the kingdom under circumstances of great barbarity, and were not allowed to return until the time of Cromwell. Before the expulsion of the Jews, however, in spite of canonical opposition, Christians had begun to take interest openly; and one of the most interesting examples of the adaptation of the dogmas of the church of Rome to the social and economic environment is found in the growth of the recognized exceptions to usury. In this respect the canonical writers derived much assistance from the later Roman law. Without entering into technicalities, it may be said generally that an attempt was made to distinguish between usury, in the modern sense of unjust exaction, and interest on capital. Unfortunately, however, the modifications which were really admitted were not openly and avowedly made by a direct change in the statutes, but for the most part they were effected (as so many early reforms) under the cover of ingenious legal fictions. One of the most curious and instructive results of this treatment has been well brought out by Walter Ross in the introduction to his *Lectures on the Law of Scotland* (1793). He shows, in a very remarkable manner and at considerable length, that "to the devices fallen upon to defeat those laws (*i.e.*, against usury) the greatest part of the deeds now in use both in England and Scotland owe their original forms" (vol. i. p. 4). One of the consequences of this indirect method of reforming the law was that in some cases the evil was much exaggerated. "The judges," says Ross, "could not award interest for the money; that would have been contrary to law, a moral evil, and an oppression of the debtor; but, upon the idea of damages and the failure of the debtor in performance, they unmercifully decreed for double the sum borrowed." He may well remark that imagination itself is incapable of conceiving a higher degree of inconsistency in the affairs of men (compare Blackstone, vol. iii. pp. 434, 435).

---

[1] For a popular account of the reasons given in support of the canonical objections to usury, and of the modifications and exceptions admitted in some quarters, see W. Cunningham's *Usury*.

In the limits assigned to this article it is impossible to enter further into the history of the question, but an attempt may be made to summarize the principal results so far as they bear upon the old controversy, which has again been revived in some quarters, as to the proper relation of law to usury and interest. (1) The opinion of Bentham that the attempt directly to suppress usury (in the modern sense) will only increase the evil is abundantly verified. Mere prohibition under penalties will practically lead to an additional charge as security against risk. The evils must be partly met by the general principles applicable to all contracts (the fitness of the contracting parties, etc.) and partly by provisions for bankruptcy. Peculiar forms of the evil, such as mortgaging to excessive amounts in countries largely occupied by peasant proprietors, may be met by particular measures, as, for example, by forbidding the accumulation of arrears. (2) The attempt to control interest in the commercial sense is both useless and harmful. It is certain to be met by fictitious devices which at the best will cause needless inconvenience to the contracting parties; restraints will be placed on the natural flow of capital, and industry will suffer. (3) In the progress of society borrowing for commercial purposes has gradually become of overwhelming importance compared with borrowing for purposes of necessity, as in earlier times. By far the greater part of the interest now paid in the civilized world is, in the language of the English economists, only a fair reward for risk of loss and for management of capital, and a necessary stimulus to saving.

For information upon the modern legislation affecting the subject, see INTEREST and PLEDGE.

On the increasing share of the products of industry given to labor compared with capital, compare Leroy-Beaulieu's *Répartition des Richesses* (1880), and E. Atkinson's *Distribution of Products* (1885) and *Margin of Profits*. (J. S. N†.)

Plate II.

UTAH, a Territory of the United States, bounded on the N. by Idaho and Wyoming, on the E. by Colorado, on the S. by Arizona, and on the W. by Nevada. The eastern boundary coincides with 109° and the western with 114° W. long. The southern boundary is the 37th parallel of latitude; the northern is on the 42d parallel between the meridians of 114° and 111°, while east of the latter meridian it follows the 41st parallel. The area of Utah is 84,970[1] square miles.

Physical features.

The surface is greatly diversified, containing high mountains, broad arid valleys, and desert plateaus. Near the middle of the northern boundary the Wahsatch Mountains enter the Territory, and they extend southward along its middle line, finally degenerating into plateaus whose elevation diminishes southward. This is the principal mountain range of the Territory, and its position marks the highest land, from which, as a watershed, the streams flow off eastward and westward, the former to the Colorado of the West, the latter to sink in the Great Basin. Eastward from the Wahsatch, along the northern boundary of Utah, stretches a broad, massive range, known as the Uintah. These mountains are exceptional in that their trend is east and west, *i.e.*, nearly at right angles to the other uplifts of the Rocky Mountain system. South of this range and east of the Wahsatch is a region of plateaus, horizontal or but slightly inclined, and receding step by step from the high mountains. In this region all the streams flow in cañons carved in the nearly horizontal sandstones and limestones, to depths ranging from a few hundreds to several thousands of feet. West of the Wahsatch stretches the Great Basin, a region having no outlet to the sea. Its surface presents an alternation of broad desert valleys and narrow abrupt mountain ranges, rising sharply from the valleys. The mean elevation of the Territory is 6100 feet. The lowest portion is near the southern border, where it is less than 3000 feet above the sea; but, on the other hand, many mountain summits exceed 13,000 feet in height. Of the principal peaks may be mentioned Mount Nebo (11,680 feet) in the Wahsatch Range, and Gilberts Peak (13,987), La Motte (12,892), and Burro (12,834) in the Uintah Range. The principal stream of eastern Utah is the Colorado of the West. This is formed by the junction of Green river, which rises in the Wind River Mountains of Wyoming, and the Grand, whose sources are in the snow-fields upon Long's Peak in Colorado. The Green and the Colorado receive numerous branches from the Uintah and Wahsatch Ranges, among them the Uintah, Price, Fremont, San Rafael, and Virgin. With the exception of the first-named, all these streams have their courses far below the general surface, in the characteristic cañons of this strange region. In western Utah the climate is very arid, and, consequently, there are few living streams. The Great Basin, of which this region forms a part, consists of a large number of basins, differing greatly in magnitude. In each of these the waters from the surrounding mountains sink or collect in a lake, which, having no outlet, rises or falls with the excess of supply or evaporation. The largest of these basins is that of Great Salt Lake, which stretches along the western base of the Wahsatch Range. The lowest part of this valley is occupied by the lake, into which drain the rivers from the western slope of the mountains, the chief being the Bear, Weber, and Ogden, while the Provo, Spanish Fork, and American Fork contribute to it through Utah Lake and the river Jordan. In former geologic times Great Salt Lake had an extent vastly greater than at present, as is evidenced by the well-marked shore-lines upon the mountains around and within its basin. These shore-lines have an altitude nearly 1000 feet higher than the present level of the lake. This higher stage, which has been named Lake Bonneville, was reduced to its present stage primarily by the formation of an outlet at the northern end of Cache valley, by which its waters flowed off through Snake and Columbia rivers to the Pacific, and secondarily by the excess of evaporation over supply. Since the settlement of the country, the surface of the lake rose, so that from an area of 1700 square miles in 1849 it had expanded in 1870 to about 2360. But in more recent years it has been slowly receding. Together with these general movements, slight oscillations with the changes of season are constantly going on. As Great Salt Lake has no outlet save evaporation, its water contains a large amount of saline matter in solution. The proportion varies inversely with the varying height of the water in the lake, ranging from 14.8 to 22.4 per cent. by weight. The only other bodies of water of considerable magnitude are Bear and Utah Lakes, both fresh and both tributary to Great Salt Lake. Besides the tributaries to Great Salt Lake, the only other stream of importance west of the Wahsatch is the Sevier, which, rising in the plateaus south of the Wahsatch, passes by a circuitous route into the deserts to the west, where it sinks. Formerly it flowed into Sevier Lake, whence its waters were evaporated, but the extensive use of the river for irrigation has caused the lake to disappear.

Geology.

The Wahsatch Range is in general terms a great monoclinal uplift, although in detail it is a complicated system of uplifts and faults. The general dip of the beds is towards the east, while the fractured edges face the Great Basin. The core of the range is composed of Archæan rocks, while sedimentary beds, as high as the Jurassic, are found upon its eastern flank. The Uintah Range is a broad anticlinal, surmounted by rocks of the Carboniferous age, with more recent formations lying upon its north and south flanks. The rocks of the plateau region are almost entirely sedimentary and lie horizontally, or nearly so. The ranges of the Great Basin are of diversified character, a large proportion of them

being monoclinal uplifts, exposing the Archæan rocks, with sedimentaries tilted upon their slopes. The valleys have in all cases a floor of Quaternary deposits, which effectually cover the rock formations that underlie them.

Fauna and flora. The animal and vegetable life presents variety corresponding with that of the topography. Upon the mountains and high plateaus are forests of *Coniferæ*, with groves of aspen skirting them at their lower limit. Here are found bears of different species, the mule deer, and occasionally the elk (wapiti) and the antelope. Upon the lower plateaus and in the desert valleys of the Great Basin life is not abundant. Piñon pine and cedar, *Artemisia*, cacti, and yucca characterize the vegetation; while of animals there are few except the coyote, prairie dog, rattlesnake, and scorpion.

Population. The settled portion of Utah lies mainly along the western base of the Wahsatch and in the valleys of that range, particularly in the northern part of the Territory. There are also considerable settlements near the southern boundary, in the valleys of the Virgin river. The population numbered 143,963 in 1880, showing an increase of 65.8 per cent. since 1870. The population is at present (1888) probably not far from 175,000. In 1850 the total was only 11,380; in 1860 it had risen to 40,273, and in 1870 to 86,786. Probably four-fifths of the population are adherents of the "Church of Jesus Christ of Latter Day Saints" or Mormons, as they are popularly designated (see MORMONISM). This proportion is steadily diminishing as the mining industries, the manufactures, and transportation increase, thus bringing in a constantly-increasing "Gentile" element. Of the aggregate population males are decidedly in excess of females: in 1880 there were 100 of the former to 93 of the latter, showing that polygamy was not generally practiced. The proportion of foreign-born inhabitants is exceptionally large: in 1880 there were 44 foreign-born to 100 natives, *i.e.*, nearly one-third of the population were immigrants. Of this foreign element there came from England, 19,654; Denmark, 7791; Sweden, 3750; Scotland, 3201; Wales, 2390; Ireland, 1321; Norway, 1214; Switzerland, 1040; Germany, 885. Thus England supplies nearly one-half and Denmark nearly one-fifth, while Germany and Ireland, which furnish the great bulk of the immigrants to the United States at large, are but feebly represented among the Mormons.

Utah is divided into twenty-four counties, enumerated, with their population in 1880, in the subjoined table.

County.	Pop.	County.	Pop.	County.	Pop.
Beaver.......	3,918	Kane	3,085	Sevier.........	4,457
Box Elder...	6,761	Millard	3,727	Summit	4,921
Cache.........	12,562	Morgan	1,783	Tooele........	4,497
Davis.........	5,279	Pi Ute........	1,651	Uintah.	799
Emery........	556	Rich...........	1,263	Utah..........	17,973
Garfield[1].....	..	Salt Lake...	31,977	Wahsatch...	2,927
Iron...........	4,013	San Juan....	204	Washington	4,235
Juab...........	3,474	San Pete.....	11,557	Weber........	12,344

The principal cities, with their populations in 1880, are,—Salt Lake City, the capital of the Territory, 20,768; Ogden, in the Salt Lake valley, at the confluence of the Ogden and Weber rivers, 6069; Provo, in the valley of Utah Lake, 3432; and Logan, in Cache valley, 3396. There are numerous other smaller places, making a large aggregate of city and village population. This is a result of the policy of the Mormon Church, which has favored the grouping of the farming population in villages.

Climate. As everywhere throughout the western United States, with the altitude above the sea there is a gradation of climate with respect to aridity. Upon the higher mountains there is sufficient rainfall for the needs of vegetation. But upon the low country the precipitation is slight, so that irrigation is almost universally practiced by the agriculturist. The annual rainfall at Salt Lake City, which is very favorably situated, being southeast of Great Salt Lake and at the immediate base of the Wahsatch Mountains, is about 30 inches. In all other habitable parts of the Territory it is less, being not greater than 10 inches in the southern and western portions. Temperature, also, has a wide range in different parts of the Territory. The mean annual temperature at Salt Lake City, which may serve as an average of the habitable parts of Utah, is about 45°. The range of temperature between summer and winter and between day and night is very great, and the changes of temperature are often startling in their magnitude and abruptness.

Industry. The principal industries of Utah are agriculture and mining. At Salt Lake City and Ogden some manufacturing is done, and in the remote parts of the Territory cattle and sheep raising is carried on to a limited extent. Agriculture is confined mainly to the Mormons, while mining enterprise is carried on almost exclusively by Gentiles. In 1880 the area of land in farms was 655,524 acres, or 1.2 per cent. of the total area of the Territory. A little over two-thirds of this was classed as improved, and nearly all the available water in the territory was used to cultivate it. The average size of the farms was 69 acres, which was less than in any other State or Territory. The total value of the annual agricultural produce was valued at $3,337,410. The number of manufacturing establishments was 640 and the value of the product $4,324,992. The principal mineral products are silver and lead, which are found associated in the same ores. The mines are situated almost entirely in the Wahsatch Range, east and southeast of Salt Lake City. During 1885 silver to the value of $6,750,000 and 23,000 tons of lead were mined. Of the latter metal Utah, next to Colorado, produces the largest quantity of any State or Territory of the Union.

Communication. Utah is well supplied with railroads. The Union and Central Pacific Railroads cross it near the northern boundary, the junction of these two lines being near Ogden. From this place a branch of the Union Pacific runs northward to Montana and another southward to Salt Lake City and thence to the southern part of the Territory. The Denver and Rio Grande Western connects Salt Lake City with Pueblo, in Colorado. In addition to these, there are numerous short branches in the mountains, making a total length of 876 miles in operation at the close of 1885.

Administration. The executive is administered by a governor and a secretary, appointed by the president of the United States, and by a treasurer, nominated by the governor. There is a legislature, the members of which are chosen by the people. The judiciary consists of a chief justice and two associate justices, together with a United States district attorney and a marshal, all appointed by the president of the United States. The Territory has no debt, The taxable property was assessed in 1885 at $34,821,957. The rate of taxation was $1.20 per $100. One-fourth of the sum raised is for the support of common schools.

Recent legislation. While in some respects the influence of the Mormon Church upon its communicants is for good, in promoting industry, economy, and sobriety, there are other features of it which are not only objectionable but dangerous. Polygamy is but an incident of the system, and the only objectionable one which can be successfully combated. The all-powerful influence of the church in things temporal as well as in things spiritual is a dangerous feature, and one which can only be corrected by slow-moving social influences. For many years Congress has been trying to frame legislation which would destroy polygamy in Utah, but until recently the action of the courts was frustrated and the laws nullified by the power of the Mormon Church. All elective offices were filled by Mormons. Juries were necessarily made up mainly of Mormons, whose obligations to the church were superior to any Gentile oath. The Edmunds Bill, passed in 1882, was the first efficient piece of legislation. This measure declared all elective offices vacant, and constituted a commission to oversee elections and appoint the judges and other officers of election. It disfranchised all polygamists. It annulled the action of the Territorial legislature in extending the ballot to women. It disqualified from service on juries all who accepted the dogmas of the Mormon Church regarding polygamy. Under the operation of this Act the leading polygamists have either been sent to jail or have gone into hiding. A bill of a still more drastic nature was passed by Congress in 1887. It annulled all Acts of the Territorial legislature designed in the remotest degree for the protection of polygamy. It provided that in trials for polygamy the wife may be a competent witness, that every marriage ceremony shall be made a matter of public record, and that all illegitimate children shall be disinherited. It annulled all Acts of the legislature incorporating and continuing the charters of the Mormon Church and of the Perpetual Emigration Fund Co., and confiscated their property, with the exception of the church buildings and parsonages, devoting it to the support of common schools in the Territory.

---

[1] Formed since the census of 1880 was taken.

History. The area of Utah was acquired by the United States from Mexico in 1848, under the provisions of the treaty of Guadelupe Hidalgo. It was organized as a Territory in 1850, and at that time it comprised all the country lying between the eastern boundary of California and the western border of the Great Plains. The subsequent creation of Nevada, Colorado, and Wyoming reduced it to its present limits. In 1847 the Mormons, under the leadership of Brigham Young, had commenced to make settlements in Salt Lake Valley, and they rapidly extended themselves over the fertile valleys of the Territory. Prior to the advent of railroads very few Gentiles settled in Utah; but in recent years, as this once remote region has become easily accessible, the Gentile element has greatly increased. For further details of the history of the Territory, see MORMONS. (H. G*.)

UTICA ('Ιτύκη), an ancient Phœnician colony in Africa near the mouth of the Bagradas (Majerda), about 20 miles northwest of Carthage. The site, which is still covered with ruins, including those of a vast amphitheatre, lies on a hill which is now 8 or 10 miles from the coast, but in ancient times a bay ran close up to the city, and the remains of quays can still be traced. Founded 1101 B.C. (see vol. xviii. p. 819), Utica was nearly three centuries older than Carthage. The two cities were generally allies; but Utica, jealous of its neighbor, sometimes acted independently, and in the Third Punic War it made a separate peace with Rome, and reaped the fruits of the destruction of the greater Punic city, becoming the emporium of Roman trade and the capital of the province, till Carthage was rebuilt by Cæsar in 44 B.C. It was here that the younger Cato killed himself. Utica received the Roman *civitas* from Augustus, was made a colony by Hadrian, and received the *jus Italicum* from Septimius Severus. The city was finally destroyed by the Arabs.

The name of Utica is probably Phœnician, and is generally taken to stand for עַתִּיקָה, the "old" city, perhaps as distinguished from Carthage, the "new city." Olshausen, however, suggests the form עֲתוּק ("colony"). The ruins at Bú Shátir were identified with Utica by Shaw. For plans and a reconstruction, see Daux, *Emporia Phéniciens*, and atlas to Tissot, *Géog. Prov. Rom. d'Afrique* (1888).

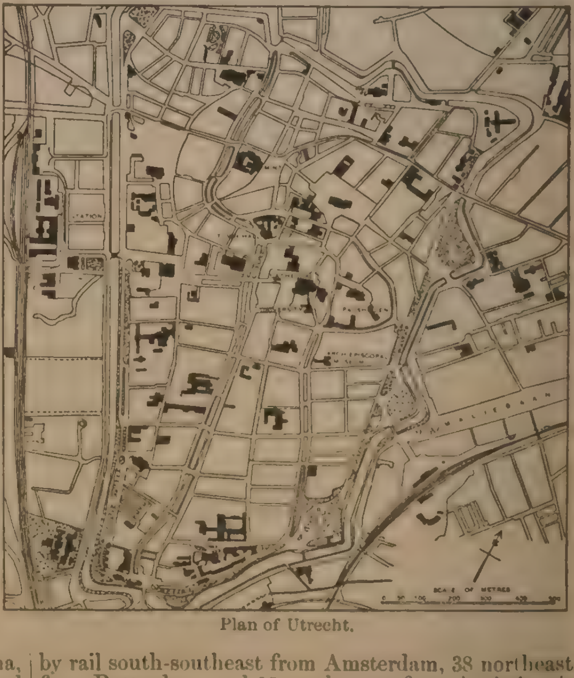
UTICA, a county-seat of Oneida county, New York, United States, about 180 miles north-northwest from New York City, is situated on the south bank of the Mohawk, about 400 feet above sea-level. The site of the city has a gentle slope towards the river. The surrounding country is thickly settled, the principal industries being the manufacture of cotton, woollen, and iron goods, the production of butter and cheese, and the raising of hops. Utica is the chief market for cheese in the United States. The city is touched by five railroads, the New York Central and Hudson River; New York, Ontario, and Western; Rome, Watertown, and Ogdensburg; Delaware, Lackawanna, and Western; and New York, West Shore, and Buffalo; and by the Erie Canal. The city is irregularly built. Of the manufacturing industries, which are varied, the most important is that of clothing, and next to it is that of boots and shoes. One of the State lunatic asylums is in Utica. The population of the city in 1880 was 33,914, an increase in ten years of less than 12 per cent., and in 1887 it was estimated at 40,000.

The first settlement at Utica was made near the middle of the 18th century. In 1798 the village was incorporated, and it received a city charter in 1832.

UTILITARIANISM. See ETHICS, vol. viii. p. 532.

UTRECHT, a province of Holland, bounded north by North Holland and the Zuyder Zee, east by Guelderland, south by Guelderland and South Holland, and west by South Holland, has an area of 534 square miles and a population (1886) of 212,454. It belongs chiefly to the basin of the Rhine: the Neder Rijn, which skirts its southern border, after sending off the Kromme Rijn at Wijk, becomes the Lek, and the Kromme Rijn, in its turn, after sending off the Vecht at Utrecht to the Zuyder Zee, assumes the name of the Oude Rijn. The northeastern portion of the province is drained by the Eem, which falls into the Zuyder Zee. In the west the province is flat and in many places below sea-level; towards the east, where the Veluwe begins, it is more undulating, and at Zeist reaches a height of 164 feet. The more productive region is in the west; towards the east the soil becomes sandy and heath-clad. Nearly half (46.5 per cent.) of the total area is under grass; the chief agricultural products are corn (buckwheat) and tobacco; bee-keeping is extensively carried on in the east, and there is a bee market at Veenendaal. The province is traversed by railways to Amsterdam, Rotterdam, Leyden, and The Hague, Bois-le-duc, Arnheim, Zutphen, and Zwolle, all converging in Utrecht; it is also amply provided with navigable water-ways. Of the total population 62 per cent. are returned as Protestant, 37 per cent. as Roman Catholic, and 1 as Jewish. Besides UTRECHT (see below), the capital, only one other town, Amersfoort, has a population exceeding 5000 (15,178 in 1887); but in density of population Utrecht ranks third among the provinces of Holland.

UTRECHT, capital of the above province, 22 miles by rail south-southeast from Amsterdam, 38 northeast from Rotterdam, and 35 nearly west from Arnheim, is situated at the point where the Kromme Rijn bifur-



Plan of Utrecht.

cates into the Vecht and the Oude Rijn. The town is traversed by two canals or arms of the river, which are crossed by numerous bridges; it is surrounded by strong forts and strategically covers Amsterdam, though its old ramparts were demolished in 1830 and have given place to shady promenades. The streets are more regular, the squares more spacious, and the canals fewer than in most Dutch towns. Of its twenty churches the most important is the old cathedral of St. Martin, a large Gothic building erected in 1254–67, on the site of the original structure founded by St. Willibrord about 720 and completed by Bishop Adelbold about 1015. Only the choir, transept, and western tower (338 feet) now remain, the nave having been blown down by a violent hurricane (1st August, 1674); the interior (30 feet wide and 115 feet in height) has been clumsily fitted up with pews and galleries for Protestant worship, so that the effect of its eighteen slender columns is almost entirely lost. On the south side are fine Gothic cloisters, adjoining which are the plain buildings of the university, founded in 1634 (with 41 professors and nearly 600 students); connected with the university are a valuable library (150,000 volumes), a museum of natural history, physical and chemical laboratories, a botanic garden, and an observatory. The town-hall (built in 1830) and the Museum Kunstliefde have small collections of pictures and other objects of art, and the archiepiscopal museum, opened in 1872, also contains excellent examples of the sacred art of the Netherlands. Among other buildings of interest may be mentioned the royal mint, and the Paushuizen ("pope's house"), built by Adrian Floriszoon Boeyens, afterwards Pope Adrian VI., a native of Utrecht, in 1517. Utrecht has excellent schools and several literary and scientific societies, besides barracks, a large military hospital, and a veterinary school. The most important industrial establishments are cigar-factories, manufactories of chemicals and earthenware, and brass foundries. There is an active trade in the produce of the manufactures, and also in corn, cattle, butter, and cheese. To the east of the town is the Maliebaan or Mall, a triple avenue of trees about half a mile in length. The population of Utrecht in 1876 was 66,106, and in 1887 it was 79,166.

Utrecht ("Oude Trecht" or "old ford"), the Trajectum ad Rhenum of the *Itinerary* of Antoninus, was known as Wiltaburg by the Frisians and Franks. Dagobert, king of the East Franks, built a chapel here in 630, and under St. Willibrord Utrecht in 696 became an episcopal see. The bishops rose to great power during the Middle Ages, and the city was frequently an imperial residence. Conrad II. (1039) and Henry V. (1125) both died at Utrecht, and their hearts were buried in the crypt of the cathedral. The city was handed over to Charles V. by Bishop Henry in 1527. The first confederation of the Dutch provinces was formed in Utrecht in 1579. The celebrated peace of Utrecht between France and Great Britain, Savoy, Portugal, Prussia, and the states of Holland was concluded here on 11th April, 1713. Utrecht has since 1723 been the headquarters of the JANSENISTS (*q.v.*).

UTRERA, a town of Spain, in the province of Seville, 18 miles to the south-southeast of that city, on the railway to Jerez and Cadiz, at the junction for Moron and Osuna, lies about 8 miles from the left bank of the Guadalquivir, in a pleasant valley between two gentle undulations of the foot-hills of the southern sierra. It has no buildings of special interest; the principal church, which is large and prominent, is Gothic in style and dates chiefly from the 15th century, but some of its most conspicuous features belong to the 17th. The place enjoys considerable prosperity, due mainly to the fertility of the surrounding district, which produces large quantities of corn, and also fruit of various sorts, oil, and wine. The uncultivated "dehesas" skirting the Guadalquivir support large numbers of sheep and brood mares, and are famous throughout Spain for the bulls they send to the bull-ring. Many of the inhabitants are enterprising landowners or large farmers, and pursue highly enlightened methods of agriculture. An important fair is held at Utrera in September. The population within the municipal limits in 1877 was 15,093.

Utrera was of some importance during the Mohammedan period and has the remains of a Moorish castle. It was taken by St Ferdinand, but did not finally become subject to the sovereigns of Castile until the reign of Alphonso XI. (1340).

UXBRIDGE, an ancient borough and market town of Middlesex, England, is pleasantly situated on the Colne and Frayswater, on the Grand Junction Canal, and on a branch of the Great Western Railway, 15½ miles west of London. The principal street is spacious and contains a number of good shops, but the streets leading off it are narrow and tortuous. The suburbs have of late greatly increased. The Colne is crossed by a brick bridge of five arches. The principal public buildings are the church of St. Margaret in the Perpendicular style, consisting of nave, aisles, and low embattled tower, the town-hall (1836), and the cottage hospital. There are a large number of charities. On the banks of the Colne are several flour-mills. The town possesses several breweries and an iron-foundry. By the Grand Junction Canal, near which there are several saw-mills, a considerable trade is carried on in timber, slates, and coal. The town is governed by a local board of eighteen members. The population of the urban sanitary district (area 496 acres) was 7497 in 1871 and 7669 in 1881.

Uxbridge was one of the small boroughs originated by Alfred the Great. It is not mentioned in Domesday. For a long period it was of considerable importance as a frontier town, and latterly possessed a regular garrison. At Uxbridge negotiations were begun on 30th January, 1645, between the commissioners of Charles I. and the Parliament, but were broken off on 22d February. In 1647 the Parliamentary forces had for some time their headquarters in the town. It remained a garrison town until 1689. It obtained the grant of a market from Henry II. Until the close of the 17th century it was governed by bailiffs.

UZ. The "land of Uz" (ארץ עוץ) is best known as the scene of the story of Job. Job seems to be represented as living in the country east of Palestine and not far from Edom, to which his friend Eliphaz the Temanite belonged. In Lam. iv. 21 the Edomites appear as in possession of the land of Uz, while in Gen. xxxvi. 28 Uz is one of the pre-Edomite inhabitants of Seir. On the other hand, in Gen. x. 23 and xxii. 21 Uz (or Huz) is Aramæan. Finally in Jer. xxv. 20 "the kings of the land of Uz" appear in a clause, absent from the LXX., which seems to be a gloss on the preceding clause, and so to refer to Arabs. Mediæval tradition places the home of Job in the Hauran (see Wetzstein in Delitzsch, *Job*), but it is doubtful whether all the Biblical references can apply to one district. The Septuagint forms from Uz the adjective *Αὐσῖτις*, which points to a pronunciation Auṣ = Arabic Auḍ, the name of a god whose worship was widely spread and might therefore be readily borne by tribes or attached to districts in several regions.

V

V is our twenty-second letter; it represents the voiced labio-dental to which F corresponds as the voiceless sound. It has been shown under U that these two symbols were originally one, and that their differentiation took place for convenience of writing only. But it was afterwards put to a good use, although not quite the natural one. It would have been better, while retaining *u* for the vowel, to have used *v* for the corresponding labial consonant, which is actually denoted by *w*. The difference of *u* and *w* is simply that of vowel and consonant: for *u* there is a sufficient opening of the lips to allow the voice to pass through without friction; but for *w* the aperture is so much closed, by bringing together either the inner edges of the lips (as in England) or the outer edges (as in some parts of Germany), that there is an audible amount of friction as the voice passes. The organs employed are the lips only in each case, whereas for *v* the upper teeth and the lower lip are the factors of the sound.

The symbol *v* does not occur in the oldest of our texts; it is represented by *f*, as in "heofon,". "ofer," "hlaford" (lord). The *f* generally is voiced when medial, but voiceless when initial. This absence of two symbols for the corresponding pairs of fricative consonants has been noted already in the use of ð (or þ) for both *th* and *dh* (see under T); *s* also did duty, as it often does still, for both *s* and *z*. In Middle English *u* appears commonly for *v*. The introduction of *v* into English writing is due to French scribes; as a matter of fact almost all the words which begin with *v* are of French origin.

It is tolerably certain that in Latin *v* represented the labial and not the labio-dental consonant. The arguments in favor of this view are singly not very important, but they are fairly numerous. The interchange of the *u* and *v* sounds, as in "genua" and "genva," "solvo" and "soluo," etc., is most easily explained on the hypothesis that *v* = *w*; so are the loss of *v* as in "audi(v)i, "ama(ve)ram," etc., and the retention of *o* after *v* in words like "cervos" (whereas in other combinations *o* sank to *u*), because "cerwoos" would have been a more inconvenient combination than "cervoos." Again, the name of the letter should have been "ev," and not "ve," like all other fricative sounds, "ef," "el," "es," etc.; but in explosives "be," "de," "pe," "te," with the vowel *following*. There is no reason why this should not have been the case if *v* were really our *v*, a labio dental; but if it was *w* the name "ew" was practically impossible, because the *w* would have been inaudible; therefore it went over to the other class of names. To these arguments may be added others drawn from transliteration. Mr. A. J. Ellis (*E. E. P.*, ii. p. 513) agrees that Latin *v* cannot have been our labio-dental, but he thinks it probable that it was the South-German *w*, which differs from the North-German *w* (our *v*, labio-dental) in the manner described above, with some other points of difference. His chief ground is that it is hard to imagine *w* producing *v* except through an intermediate labial of the North-German kind. There is something in this argument. In any case the difference between these two *w*-sounds is slight compared with the difference between either of them and the labio-dental *v*. At what time the labial passed into the labio-dental of the Romance languages is uncertain. We can fix limits of time before which the change must have taken place: *e.g.*, it must have been before the time when the Romanized Gauls, trying to pronounce the Teutonic *w* in "werra," "ward," etc., produced "guerra," "guard," etc. If their *v* had then had the *w*-sound there would have been no difficulty in producing the same sound in Teutonic words.

In the Roman system of numerals V stands for five. The reason is uncertain. The old view that it represents half ten (X), as D (500) represents half a thousand (M, originally ⊕), has no very high degree of probability. It is perhaps as likely that I., II., III., IIII., denoted the uplifted fingers used in counting, and that V denoted the whole hand with the thumb on one side and the four fingers together on the other.

VACCINATION (from Lat. *vacca*, a cow), the name given in France to the Jennerian practice of cowpoxing, shortly after the practice began in England (1799). The procedure was based almost exactly on the earlier practice of inoculating the smallpox, the matter being inserted under the skin of the arm by a lancet point; also the continuance of the same stock from arm to arm through a series of cases was an idea taken from some of the more adroit variolators. To replace smallpox inoculation by cowpox inoculation under certain specified circumstances was Jenner's tentative project. The history of the introduction of cowpoxing, given in the article JENNER (vol. xiii. p. 634), is here supplemented from the point of view of historical criticism.

Relations of smallpox, cowpox, and grease of horse.

It is right to say that the views expressed in the present article diverge in many points from the opinions generally received among medical men, and must be regarded not as the exposition of established and undisputed doctrine, but as the outcome of an independent and laborious research.

Jenner.

Jenner's originality consisted in boldly designating cowpox as *variolæ vaccinæ* or smallpox of the cow, and in tracing cowpox itself back to the grease of the horse's hocks. The latter contention was at length set aside by practical men as a crude fancy; the former designation is just as arbitrary and untenable. It was elaborately shown by Pearson in 1802, and has often been confirmed by subsequent writers, that the vesicle of inoculated cowpox, even while it remains a vesicle, is quite unlike a single pustule of smallpox. But it is only for the vesicular stage of cowpox that there is even an allegation of likeness to variola; the vesicle of natural or unmodified cowpox is only the stage of the disease before it becomes an ulcer, either inflammatory or indurated. Inoculated horse-grease has the same vesicular stage; and so also has the venereal pox when it is inoculated experimentally on the skin.[1] These three very different infections have the same kind of vesicle, in every case unlike a smallpox pustule, and the same natural termination in a phagedenic or indurated sore.

Jenner's originality in starting vaccination in practice is for the most part misunderstood. When he published his *Inquiry* in June, 1798, he had twice succeeded in raising vaccine vesicles by experiment, the first time in 1796 with matter from a milker's accidental sore, and the second time in March, 1798, with matter direct from the cow. The first experiment was not carried beyond one remove from the cow; the second was carried to the fifth remove, when the succession failed. A third experiment, in the summer of 1798, failed from the outset; and his fourth and last experiment, in November–December, 1798, led to nothing but extensive phagedenic ulceration in two cases out of six vaccinated.

Historical sources of vaccine lymph.

In this posture of affairs Woodville, of the inoculation hospital, London, succeeded in January, 1799, in starting a succession of arm-to-arm vaccinations from a London cow, which were exceptionally free from the ulcerative termination. From that source Jenner himself was supplied with lymph in February, while more than two hundred practitioners, both at home and abroad, were supplied some three weeks later. There was a quarrel with Woodville in due course, and an attempt to set up an authentic Jennerian lymph independent of the London stock. But the merits of this claim (which otherwise rests on the vague evidence of Marshall) may be judged of by the fact that Ring's application to Jenner in September, 1799, for genuine lymph was answered by the latter with a supply of matter which was none other than Woodville's own stock, after six months' use in the country. Woodville's stock was used all over the world down to 1836. By that time there were numerous complaints that the lymph was degenerating, and a widespread feeling that it was necessary to "go back to the cow." Apart from the numerous original cases of cowpox alleged to have been found in Würtemberg, the first new authentic source was the Passy cow of 1836. From the accidental vesicles on the milker's hand Bousquet, the director of vaccination in Paris, started a new stock, which partly superseded Woodville's lymph hitherto in use in France. In 1838 Estlin of Bristol, after several years' vain endeavors, heard of original cowpox in Jenner's own parish of Berkeley (Gloucestershire), where the disease was so far forgotten that the milkers were for several days unaware that the vesicles on their hands had been contracted from cows. Estlin's new geniture is one of the most fully recorded in the history of vaccination. In the same year, and the two following years (1838–41), Ceely of Aylesbury found some half-dozen distinct occurrences of cowpox in the dairy-farms of his district, and cultivated lymph from them. His account of the natural history of cowpox in the cow, and of the effects of primary lymph when inoculated on the human arm, is by far the most comprehensive and candid that has ever been given; without it we should hardly have understood the real nature of cowpox. Bousquet, Estlin, and Ceely are the chief writers who have authentically described the establishment of new stocks of cowpox lymph since Woodville's original report of 1799. There are numerous other references, less detailed, to original cowpox in the cow, and to vaccinations therefrom, in England, on the Continent, and in the United States; some of these came to light in the inquiry of the Epidemiological Society in 1852. One of the best-known cases of comparatively recent times is the Beaugency cow of 1866, which has been the source of much of the calf-lymph of the Dutch, Belgian, and other vaccine "farms." Another French case occurred in the Gironde in November, 1881, and is described in the *Bulletin* of the Academy of Medicine (p. 17, 1882). In England the editors of the *Veterinarian* inserted a notice in the number for August, 1879, making a request to their readers for lymph "from vesicles on the teats of cows in cases of so-called natural cowpox." The only answer to it hitherto has been an intimation in June, 1880, that there was a case of cowpox at Halstead in Essex, which was visited by Ceely and others and pronounced by the former to be of the nature of eczema. In 1876 the disease was found at a farm near Reykjavik in Iceland, where it had never been seen before; it was of the old type, producing sores on the milkers' hands, and causing much alarm by its unfamiliar character.[1]

---

[1] See Ricord, *Traité Complet*, 1851, plate i. Figs. 6 and 7 and ii. 7, 8, and 9; also H. Lee, *Med. Chir. Trans.*, xliv. p. 238, 2d plate, Fig. 2.

Calf-lymph.

The so-called calf-lymph is as remote from the cow as ordinary humanized lymph; it differs from the latter merely in the circumstance that the calf (on its shaven belly) becomes the vaccinifer, instead of the child, and that the cycle of the disease is very much abbreviated or contracted in the calf: the vesicles are distended with lymph about the fourth or fifth day, instead of the seventh or eighth, and are almost unattended by areolar redness and constitutional disturbance, the animal being able to support fifty to a hundred or more vesicles without the smallest inconvenience. On the child's arm the vesicles after calf-lymph are slower in development than in the calf, and are attended by areola, etc.

Under the influence of theory, "vaccine" lymph has been got from two sources that have absolutely nothing to do with cowpox; and, oddly enough, the matter from these sources has been so managed as to produce correct vesicles on the child's arm. One source is the grease of the horse's hocks and the other is smallpox itself.

Anomalous sources of vaccine.

Grease of the horse.

The grease of the horse was known to produce vesicles and subsequent ulcers on the hands almost indistinguishable from those of accidental cowpox. There was also the tradition (which breaks down when tested by facts) that accidental infection with the grease protected from smallpox. Jenner held that all "genuine" cowpox came from horse-grease; and, after he had raised vaccine vesicles on the arms of children by matter from the cow's teats, he proceeded to try whether he could not raise the same kind of vesicle experimentally by matter once removed from the horse's hocks. The experiment succeeded, just as the accident had done. The vesicle (represented in plate 2 of the *Inquiry*) ulcerated, and the boy died of what is vaguely termed a "fever" in one place and a "contagious fever" in another. The same kind of inconsequent logic suggested the experiment of inoculating the matter of horse-grease upon the skin of the cow's teats, the object being to prove the identity of cowpox with the grease. That too succeeded in the hands of Loy of Whitby. Loy also inoculated children with the same matter, and raised vesicles on their arms, which were, of course, the same as the accidental vesicles (compared to the blister raised by a burn). Sacco of Milan actually used the equine matter on a large scale, instead of cowpox matter; and De Carro of Vienna "equinated" many persons in that city with lymph sent him by Sacco. Baron prints a memorandum of Jenner, dated 23d July, 1813, relating to "equine virus which I have been using from arm to arm for these two months past, without observing the smallest deviation in the progress and appearance of the pustules from those produced by vaccine," and a second note, dated 17th May, 1817, in which Jenner says he "took matter from Jane King (equine direct) for the National Vaccine Establishment. The pustules beautifully correct." This is not the place to enter upon the pathology of horse-grease; and, as a matter of fact, equination has not been much practiced on the whole. According to Jenner's own data, it was an occasional constitutional disease of the horse's hocks in wet seasons, which was communicable to the hands of men in the form of large whitish vesicles, ending in corroding and painful open sores (see the case reported to him by Fewster, *op. cit.*, ed. 1800, p. 96).

Human smallpox.

The other anomalous source of "vaccine" is human smallpox. Jenner having succeeded in passing off his doctrine that cowpox is smallpox of the cow, it occurred to some persons about forty years after to prove the doctrine by experiment, the proof being to variolate the cow on the udder. This was accomplished in 1838, after much trouble, by Thiele in Kazan (Russia), who inoculated several thousands of persons with the variolous matter "passed through the system of the cow." Within a few months of that experiment, the same thing was attempted by Ceely of Aylesbury, who succeeded, after many failures, in raising a large variolous pock, not on the udder of the cow, but on the mucous membrane of the vulva. The first experiment with the matter of this pock was undesigned; his assistant pricked his hand with the lancet which had just been dipped into the large pustule, and in due course had an attack of smallpox. Ceely persevered with his experiments (having meanwhile variolated another heifer at five places on the vulva), and in due time so "managed" his matter as to produce vesicles on the human arm (without general eruption on the skin), which were regarded at Cheltenham and other places as on the whole better than the cowpox vesicle of the period. But the real practical application of this idea was reserved for Badcock, a dispensing chemist at Brighton. It does not appear that any authentic or fully detailed account of Badcock's experiments has been published;[2] but he thus summarized the results some forty years later (*Pall Mall Gazette*, Jan. 23, 1880): "By careful and repeated experiments I produced, by the inoculation of the cow with smallpox, a benign lymph of a non-infectious and highly protective character. My lymph has now been in use at Brighton for forty years, and is at the present time the principal stock of lymph employed there, being that exclusively used by the public vaccinators." At Boston, U. S., the same kind of lymph was raised and put in use in 1852. But at Attleborough, Mass., the same experiment had in 1836 led to disaster. Smallpox was inoculated on a cow's udder, and the product used to vaccinate about fifty persons. The result was an epidemic of smallpox, a panic, and the suspension of business.[3] On the face of it this method was simply variolating the cow (on a mucous membrane if the hairless or shaven skin failed) and inoculating the human subject with that curiously disguised smallpox matter. However, it was thought necessary to hold an experimental inquiry upon it, and in 1865 a commission of the Lyons Society of Medicine reported that, "in vaccinating according to the method of Thiele and Ceely, we are merely practicing the old inoculation, rendered uniformly benign, it may be, by the care taken to inoculate only the first product (*l'accident primitif*), but preserving for certain all its risks in respect to contagion."[1] A negative result was come to by Klein in 1879, in an inquiry for the local Government Board, wherein he had Ceely's co-operation. In 1879 the Irish Local Government Board prevented the use of similar variolous lymph by threatening to prosecute under the Act making the inoculation of smallpox penal. Notwithstanding the common sense of the case, and these experimental proofs, the official view taken by the medical department in 1857, that Thiele, Ceely, and Badcock had established the correctness of Jenner's doctrine of variolæ vaccinæ, is still held very tenaciously by the profession. It is too simple and attractive to be soon given up; but perhaps the best way to get rid of it is to state in plain terms what cowpox itself really is.

---

[1] Cowpox of the original ulcerating type still occurs, but is now hardly recognized as such. The inquiry into an outbreak of scarlet fever in December, 1885, traced to a dairy at Hendon (Middlesex), elicited the fact that the inculpated cows, as well as seventy or eighty at two other farms, were affected with what the dairymen called "cowpox" (see Cameron, *Trans. Epid. Soc.*, April, 1886). A similar outbreak in November, 1887, involving 160 cows and 7 milkers at four farms in Wiltshire, was clearly proved by Crookshank to be the historical cowpox of Jenner and Ceely, by the evidence of identity in the sores on the cows' teats and in the sores or vesicles on the milkers' hands or faces, and by the production of correct vaccine vesicles in calves inoculated with lymph from a vesicle on the face of a milker (*Brit. Med. Journ.*, 17th December, 1887, and 21st January, 1888).

[2] See Hodgson, *Brit. Med. Journ.*, 26th November, 1881.

Natural history of cowpox.

Although there is no difficulty in drawing up a complete natural history of cowpox, thanks to the laborious and exact studies of Ceely, yet the attention has been so much diverted to side issues that the facts to be stated in this section will come before most readers with the aspect of novelty. The other original authorities besides Ceely are Jenner himself, Pearson (who collected information by circular in the months following Jenner's *Inquiry*), Bousquet (1836), Estlin (1838), and Crookshank (1888). The Würtemberg inquiry, published by Hering (Stuttgart, 1839), is made up of very indifferently authenticated or incomplete statements, which have not the same value as the rest, and are at variance with them on the most essential points.

Its origination.

Its infective properties.

Cowpox as an infective disease arises in cow-houses here and there, and at wide intervals of time, out of a common physiological or constitutional eruption of some particular cow, usually a heifer in her first milk, very often in the spring season or at some other crisis of the year or of the animal's life history. It never arises except in milch cows; it occurs nowhere in the cow but on the teats, or, by infection, on adjoining parts of the udder. All the characters by which we know it distinctively as cowpox are associated with the fact of milking, or with the inevitable traction on teats that are the subject of an otherwise unimportant eruption. The primary disorder, as Ceely describes it, is an eruption of a few pimples, the size of a vetch or larger, hard and solid at first, but at length slightly vesiculated on the summit. It is only rarely that a series of events ensues on this basis which constitute cowpox as we know it; they ensue in some one animal out of many in the same byre, and years may elapse before the event happens again. The pimples on the teats are made to bleed by what Ceely calls "the merciless manipulations of the milkers"; the blood forms crusts, which are dislodged every six hours; and indurated ulcers form on the sites of the original pimples. The process being thus made inveterate owing to the incessant interference of the milker's hands, it becomes communicable to the other cows. The milkers can usually point out some one cow in which the disease began; and it spreads slowly through a byre, taking sometimes as long as three months to go the round of all the animals. An animal already infected at one or more places on its teats may become infected at other places on the teats and body of the udder, either by the traction of milking or by the contact of parts when the cow is lying down.

Progress of the disease.

The ulcers heal sometimes slowly, sometimes more quickly; they may heal under crusts, or as open sores; induration and rounding of the edges are distinctive, along with much thickening of the base. The scars are also indurated, rounded and elevated at the edges, and smooth or puckered on the surface; they are often as large as a walnut. It is not easy to see a vesicular stage of the disease even in the cows infected from the initial spontaneous case; and Ceely had for the most part to be content with the coagulated matter of crusts to vaccinate with. The process is, in fact, bound up from first to last in the most intimate and essential manner with the operation of milking. Cowpox "undisturbed by the milker's hands" has no existence in the originating cow; it is the persistent irritation that makes it a pox. It is communicable, also, to the hands of the milkers themselves, and by their filthy hands to their faces. Jenner mentions a good many such cases; Pearson has collected several; and Ceely gives three in very full detail. As in the inoculated venereal pox, the infection proceeds for a time under the skin, making a bluish-white vesicle; it eats away the tissues round the margin, where the fluid makes the skin bulge out into the characteristic tumid ring. After the fourteenth day the vesicle will have become an eschar, the average size of a sixpenny piece, which comes away and leaves a sore. The open sore is a regular part of the infection in the milker's hand. Various regions of the face get infected by contact from the hands: Jenner mentions the case of "a poor girl who produced an ulceration on her lip by frequently holding her finger to her mouth to cool the raging of a cowpox sore by blowing upon it"; another of Jenner's cases had the sore on the wing of the nose; one of Ceely's cases had an ulcer on the temple three-quarters of an inch long; in a case observed by Crookshank there was a very large vesicle and subsequent sore over the left cheek bone. The local infection is accompanied by constitutional disturbance, more or less severe, including headache, pains in the loins, vomiting, and sometimes delirium. The axillary glands become painful, usually about the fourth day, and remain hard for some time. Eruptions occurred, but there is very little said about them.

Humanized cowpox.

As might have been expected, the effects of experimental infection with cowpox matter were the same as the accidental. They are spoken of as the effects of "primary lymph," that is to say, lymph direct from the cow's teats or from the milker's sore hand, or in the earlier removes from these sources. Jenner's experience of primary lymph was very much the same as Bousquet's, Estlin's, and Ceely's forty years later. Woodville's, on the other hand, was exceptionally reassuring;[2] had it not been so, it is not likely that cowpoxing on the large scale would ever have survived the initial discouragement entailed by the use of primary lymph. The process on the child's arm was on the whole the same as on the milker's hand, allowing for the more deliberate mode of inoculation and for different texture of the skin. The vesicle grew to a great size up to the fourteenth day, and often became an ulcer, either excavated under the crust or absolutely open. Estlin did not entirely get rid of ulceration until after the twenty-ninth remove from the cow. The constitutional disturbance was often severe in infants: axillary tenderness and swelling were somewhat constant, and eruptions were especially frequent about the second to the fourth week, including macular roseola, lichen, and pemphigoid bullæ. At each successive remove from the cow the cycle of the process became more contracted, and the constitutional disturbance, *cæteris paribus*, became less. Bousquet gives a plate which shows by parallel series of figures the differences between the vesicles of the old lymph (Woodville's, nearly forty years old) and the lymph from the Passy cow. The new lymph induced a process more protracted at every stage: the vesicle continued to enlarge at the periphery for several days after the common vaccine vesicle of the period would have ceased to extend. It was not at its maximum until about the end of the second week, and it then became an eschar and a sore. Bousquet confesses that he first understood "les frayeurs de Jenner" when he saw the ulcerative and other effects of primary lymph. After a certain number of removes from the cow the cycle became so contracted that the vesicle was full at the eighth or ninth day; the abbreviation of its life history enabled it to heal without ulcerating. It thus becomes the ordinary vaccine vesicle as we know it, which heals under a scab, and leaves the peculiar punctated scar of subcrustaceous repair. The abbreviation or mitigation is effected by taking lymph from each successive vaccinifer at as early a period as it can be got, until the golden mean of safe vaccination, namely, maturity at the eighth day, is reached. That corresponds to Jenner's rule of taking the matter for vaccination before the areola appears; if the vesicle be emptied after that period, the lymph from it is apt to cause ulceration, or, as Ceely puts it, we have "all the inconveniences of primary lymph." It is thus clear that humanized cowpox might be easily cultivated back to its original type; and, as a matter of fact, it has sometimes been so cultivated back by misadventure, with serious consequences to the vaccinated.

---

[1] *Vaccine et Variole*, Paris, 1865, p. 101.

[2] But Addington (*On the Inoculation of the Cowpox*, Birmingham, 1801), who got his lymph from Woodville, was not equally fortunate: of eleven cases at the beginning of his series five ended in ulceration; after that the cases all ended in a "dry scab."

Risks of vaccination.

The risks of vaccination may be divided into the risks inherent in the cowpox infection and the risks contingent to the puncture of the skin. Of the latter nothing special requires to be said; the former will be discussed under the five heads of (1) erysipelas, (2) jaundice, (3) skin eruptions, (4) vaccinal ulcers, and (5) so-called vaccinal syphilis.

Erysipelas.

(1) A slight degree of erysipelas was recognized by Jenner himself, and even postulated by him, as part of the natural history of cowpox in man; and it is so recognized by the more unbiassed writers of recent date.[1] The usual time for it corresponds to the appearance of the areola (eighth or ninth day), that efflorescence round the pock being normally a slight erysipelas. It may start, however, from the puncture or scratch in the skin, after a day or two's interval; but that form of it (the "early erysipelas" of German writers) is much rarer than the erysipelas of the areola, or "late erysipelas." Primary lymph, or lymph in the first removes, is most apt to excite an extensive and spreading areolar redness. In the ordinary course of vaccination remote from the cow the intensity of the superficial redness and deep infiltration would seem to depend mostly on the child's constitution, or on whatever concurrence of circumstances serves to recall the "inconveniences of primary lymph." The registrar-general's tables of mortality for England and Wales have contained an entry of "erysipelas after vaccination" from 1855 down to 1881, when the entry was changed to "cowpox and other effects of vaccination," the numbers at the same time nearly doubling. The fatal cases of erysipelas in infants under one year referred to vaccination are but a small fraction of the whole mortality from erysipelas at that age, a mortality which is far greater than at any other period of life. It is quite certain that in foundling hospitals, such as that of St. Petersburg, the erysipelas of vaccination has been the starting-point of disastrous epidemics of erysipelas affecting the inmates generally. There is no means of knowing whether the same has been the case among the population at large. In Table I. the column of deaths from erysipelas in general, among infants of the first year in England and Wales, is given side by side with the column of deaths from erysipelas after vaccination. The post-vaccinal inflammation sometimes takes the form of phlegmon; but there is no separate entry for that as a special sequel of vaccination. Many of the alleged deaths from erysipelas after vaccination have been the subject of coroner's inquests; the verdict is often an open one, and even such cases as those near Gainsborough in 1876 and at Norwich in 1882 were found to have been returned (all but one) by the certifying medical practitioners as due to erysipelas merely. It may be assumed that "after vaccination" is not certified unless the case has left no doubt in the minds of the jury or of the certifying medical attendant. The increase in the first column from 0 in 1855 to 32 in 1880 is probably in appearance only, and due to more correct diagnosis.

TABLE I.

	Erysipelas after Vaccination.	Erysipelas.		Erysipelas after Vaccination.	Erysipelas.
1855	0	583	1870	20	685
1856	5	610	1871	22	716
1857	0	421	1872	16	617
1858	0	599	1873	19	675

1863	7	612	1878	35	582
1864	11	618	1879	31	561
1865	10	579	1880	32	618
1866	9	527	1881	56[2]	644
1867	3	467	1882	65[2]	696
1868	8	647	1883	51[2]	641
1869	19	589	1884	49[2]	618

Jaundice.

(2) It is only within the last few years that jaundice has been recognized as a post-vaccinal effect; and at present there is only one accepted instance of it on the large scale. This was the epidemic among re-vaccinated adults in a large shipyard at Bremen from October, 1883, to April, 1884. Owing to an alarm of smallpox, 1289 workmen were re-vaccinated between the 13th August and 1st September with the same humanized lymph preserved in glycerin; of these 191 had jaundice at various intervals down to the month of April following. Circumstantial evidence (agreement and difference) clearly traced the epidemic to the vaccination.[3] In future an outlook will be kept for this effect of vaccination; at present it has no intelligible theory. It may be noted that the lymph which caused the Bremen epidemic was mixed with glycerin.

Skin eruptions.

(3) The eruptions that follow vaccination are proper to cowpox infection. Although little is said about them in the accidental infection of milkers, they were very common in the practice of Estlin, Ceely, and others with primary lymph. The eruption is a kind of exanthem, or "secondary" of the local infection, and does not ordinarily appear before the second week. One of its commonest forms is a patchy rose-rash, or macular roseola, not easily distinguishable from the macular roseola of syphilis.[4] Another form is lichen or dry papules, apt to scale; it may also occur as a vesicular eruption, and in the form of pemphigoid bullæ or blebs. In one of Ceely's cases the eruption extended to the whole mucous membrane of the mouth and throat. A peculiarity of the exanthem is that it may come and go several times before it finally disappears; and, like other skin eruptions, specific or non-specific, it may become inveterate. The widespread belief that much of the eczema of childhood dates from vaccination is not by any means to be dismissed as a mere fancy. The skin-disorders that followed vaccination in the first years of the practice were declared by Birch and others to be new in type. At present the vaccinal eruption, especially on the scalp, is sometimes distinguished by the size and form of the crusts, and by scars remaining for a time.

Vaccinal ulcers.

(4) Ulceration of the vaccine vesicle, or of the site of it, is one of the commoner forms of "bad arm." It is a return to the native or untamed characters of cowpox on the cow's teats, or on the milker's hands or face, or in the child's arm after experimental inoculation with primary lymph. It crops out not unfrequently in everyday practice, and is probably dependent for the most part on the lateness at which the lymph was taken for vaccination, or on retardation of the process in the vaccinifer, or on emptying the latter's vesicles too much; however, it may result from picking the scab or otherwise dislodging it. The ulceration usually proceeds to some depth in the form of a crater under the crust, and is attended with induration and rounding of the edges and induration of the base. According to Bohn (*op. cit.*, p. 166), it may alarm practitioners by its resemblance to syphilis. In other cases the crust is wanting and the ulceration has the distinct type of phagedena. The destruc-

tion of tissue in either case may be very extensive, going "down to the bone" and having as much as an inch or more of superficial area. Healing is frequently an affair of weeks, and may be aided by mercurial treatment. There are no statistics of this sequel of vaccination; but the frequency or infrequency of it may be learned in conversation with any intelligent chemist whose shop is resorted to by the poor, or with a medical practitioner of average experience.

Vaccinal syphilis.

(5) It has been proved by many experiments, undesigned or otherwise, in Paris (1831 and 1839), Vienna (1854), and elsewhere, that an infant with congenital syphilis develops correct vaccinal vesicles, provided its skin be clear of eruption and the lymph have been taken at the usual time; also that the lymph taken from the correct vesicles of a syphilitic child produces correct vesicles in its turn, but does not produce syphilis in the vaccinated child. The congenital taint is, in fact, irrelevant to the course of cowpox infection. So far as experiment and casual experience can prove anything, that has been proved; the recent attempt to disprove it by an officer of the Local Government Board (*Report* for 1882, p. 46) is vitiated by fallacies, and has no value against the overwhelming testimony collected thirty or forty years ago. What, then, is the meaning of the numerous outbreaks of syphilis in groups of children or adults vaccinated or re-vaccinated with lymph from one source?

A careful examination of these cases shows that syphilis at the source of the vaccine matter was in all cases an afterthought, that in most of the cases there was no evidence for it, and that in the remaining cases the evidence was so far-fetched as to be unlikely (apart from the known *a priori* improbability), or that the traces of constitutional infection found in the vaccinifer were subsequent to vaccination, and therefore capable of being explained as an effect concurrent with the more obvious symptoms in those vaccinated therefrom. The effects, however, were very much the same as in the venereal pox. The vaccine vesicle, either became an indurated or phagedenic sore, as described in the foregoing section on vaccinal ulcers, or the scar opened into an indurated sore after the usual subcrustaceous healing was complete or became indurated without opening. The axillary and cervical glands were often indurated. In most of the epidemics there were a certain number of cases in which the effects were purely local, or confined to one only of the seats of puncture; if these had not occurred along with others in a group, they would have been counted as ordinary vaccinal ulcers. But there were often secondary symptoms as well, including the roseolar, lichenous, or (rarely) pemphigoid eruption, and not unfrequently condylomata *circa anum et genitalia*. In some epidemics (but not in all) there were, in a small minority of the cases, mucous patches on the tonsils, tongue, or lips, tending to ulcerate; and in some of the Italian outbreaks the infection spread among the mothers and other members of the households in the form of specific sores of the nipples, with or without constitutional symptoms. Affections of the bones and viscera do not seem to have followed; fatalities were not very common.

It will be hard to persuade medical authorities that these secondary effects are not the result exclusively of the venereal pox. The evidence, however, does not allow us to assume any other specific infection than that of cowpox, which, as we know, has its proper secondary exanthem in the form of macular roseola, lichen, or pemphigus; the eruption has even been known to affect the mouth and throat. The evidence from epidemics of vaccinal sore arms teaches us that condylomata, mucous patches of the tonsils, tongue, and lips, and even iritis, are also possible, although far from invariable, among the "secondaries" of the primary vaccinal ulcer. The most general fact that comes out in these epidemics is that the lymph was taken late from the vaccinifer, or that the vesicles of the vaccinifer were drained dry to vaccinate a large number, or that the same vaccinifer was used for arm-to-arm inoculation on two successive days. It is not difficult to see how, in those circumstances, the abbreviated cycle of humanized cowpox may be departed from and the native or untamed characters of cowpox infection reverted to. Cowpox, indeed, is parallel with the venereal pox, both in the circumstances of its becoming an infective ulceration (indurated or suppurating) and in its secondary or constitutional manifestations as an infection in man. But the "bad" lymph has hardly ever been used beyond the second remove; and there the parallel fails.

The following is a list of the so-called syphilitic epidemics after vaccination, including those that have been considered spurious, because they were either anomalous in type from the point of view of syphilitic infection or had no obvious causal connection with that disease.

Udine, 1814 (see Viennois, in *Syph. Vaccinale*, p. 221). Cremona, 1821 (see Depaul, "Projet de Rapport," in *Syph. Vacc.*). Grumello, 1841 (*ibid.*). Coblenz, 1849 (Wegeler, in *Preuss. Vereins-Ztg.*, 1850, No. 14; abstract in *Schmidt's Jahrb.*, vol. lxvii., 1852, p. 62). Upper Franconia (the Hübner case), 1852 (*Intelligenzbl. der Bayr. Aerzte*, 1854; Bohn, *loc. cit.*). Lupara (Italian prov. Molise), 1856 (see Depaul, *loc. cit.*). Dispon near Pesth, 1855-57 (*Oester. Zeitschr. für prakt. Heilk.*, 1862; Bohn, *loc. cit.*, p. 322). Rivalta (Piedmont), 1861 (Pachiotti, *Sifilide Trasmessa per Mezzo della Vaccinazione in Rivalta presso Acqui*, Turin, 1862). Torre de' Busi near Bergamo, 1862 (see Depaul, *loc. cit.*). United States (troops on both sides in the Civil War), 1861-65 (Jones, *Circular II., Louisiana Board of Health*, Baton Rouge, 1884). Argenta near Ferrara, 1866 (Gamberini, in *Gaz. des Hôpitaux*, 1870, p. 505). Morbihan (neighborhood of Vannes and Auray), 1866 (Depaul, *Bull. de l'Acad. de Méd.*, xxxii., 1866-67, p. 201; Bodelio, *ibid.*, p. 1033). Cardaillac (Lot), 1866 (*Bull. de l'Acad. de Méd.*, 28th February, 1867). Schleinitz (Styria), 1870 (Kochevar, *Allgem. Wiener Med. Ztg.*, 1870, Nos. 21 and 24; abstract in *Arch. für Dermatologie und Syph.*, 1870). London (two series), 1871 (Hutchinson, *Med. Chir. Trans.* liv., 1871). Switzerland, 1878 (*Bull. de la Soc. de la Suisse Romande*). Algiers, 1880-81 (*Journ. d' Hygiène*, 25th August, 1881). Lyck (East Prussia), June, 1878 (Pincus, *Vierteljhschr. f. gericht. Med.*, 1879, p. 193). Asprières (Aveyron), March, 1885 (P. Brouardel, *Rapport*, Paris, 1886).

Attention was drawn to these cases because they occurred in groups varying in number from 10 to 100 or more, which made considerable stir, especially in country districts. It is unlikely that all cases have been reported. In the third *Report* of the clinical hospital of Manchester, Whitehead states the results of his inquiries on post-vaccinal illness in children. Setting aside most of the cases of illness vaguely alleged by the mothers to have been the consequence of vaccination, he admits as truly post-vaccinal 34 cases of syphilis or pseudo-syphilis; of these he enumerates only 14 in his table of 63 cases of children's syphilis of all kinds, the other 20 cases being omitted, it would appear, not because there was any doubt of their being post-vaccinal, but because they were not of the perfect type of infantine syphilis. Such was the experience of a competent observer at a single hospital during a period of 20 months. Whitehead's *Report* was published in 1859; but, when Hutchinson published his first series of London cases in 1871, the subject was considered to be quite new. Here again it was the concurrence of some ten cases in a group that helped the reluctant assent of the profession. The first group of London cases had hardly begun to be talked of when one of Hutchinson's colleagues was led by two cases of skin disease at a hospital to follow up the traces of another group, the very existence of which was unsuspected by the public vaccinator or general practitioners in whose district the eleven patients with vaccinal ulcers and occasional secondaries resided.

In the registrar-general's tables of mortality for England and Wales about one-half of the deaths from "cowpox and other effects of vaccination," or nearly thirty per annum, may be put down to effects of vaccination other than erysipelas; but there is nothing to show that these were fatal cases of vaccinal ulcers with constitutional symptoms or marasmus. On the other hand, the table of deaths from syphilis shows an enormous and steady increase in the number of deaths of infants under the age of one. In the first

---

[1] The proportion assigned to the first year of life is calculated from the specimen table for 1852 (females only) and from the tables of London mortality.

year of compulsory vaccination (1854) the deaths suddenly increased by one-half, and the increase has gone on steadily since then (see Table II.). The interpretation of the fact is by no means easy or free from fallacies. There are doubtless other and better reasons for the increase besides vaccination; and it is significant that the tables for Scotland show the mortality to be chiefly in the first three months of life, whereas the statutory limit for vaccination in that country is six months.

Other alleged effects of vaccination.

In the polemical writings of anti-vaccinists, such diseases as scrofula, tubercle, hooping-cough, diarrhœa, and other common causes of infantine mortality are alleged to have increased owing to vaccination. There is little or no reason, in theory or in experience, to suspect that tuberculous or scrofulous infection is ever communicated by vaccine lymph. As regards the above and other infantine maladies, vaccination may predispose the child to fall into them, in so far as it produces, or ought in theory to produce, a considerable constitutional disturbance and presumably a loss, for a brief period, of the natural power to resist the various noxious influences by which the age of infancy, especially among the poor, is beset.

The value of cowpox as a protection against smallpox may now be judged of apart from the fanciful doctrine of variolæ vaccinæ by which it was originally recommended. It has been put to a test extending over eighty years; and in some circumstances it has been possible to apply the logical methods of agreement and difference with a good deal of cogency. The besetting fallacy of all vaccination logic is that of *post hoc ergo propter hoc;* and the only way to escape it is to hold intelligent views of the history, the natural history, and the epidemiology of smallpox. This will necessitate a brief excursus.

Smallpox.

Smallpox, which is really a tropical skin disease of the nature of lichen turned pustular, or of ecthyma, must be judged according to what we know of foreign pestilences in general. Perhaps we are safest to take a line through the behavior of the plague. Plague in western Europe had the start of smallpox by a good many years, if we speak only of prevalence on the large scale. "Throughout the 16th century," says Hirsch, "the plague was a permanent form of disease on the continent of Europe. . . . During the first two-thirds of the 17th century we still meet with it over an equally wide area and equally often. But in the last thirty years of that century the plague was observed to be retreating gradually from the soil of Europe." It was not only in London after the fire of 1666 but also in Denmark and Sweden, in Italy, in Holland and Belgium, in Switzerland, in France, in western Germany, and in Spain that the years 1660–1680 saw the last of plague; it lingered only in the Levant, in Poland, and in other parts of northeastern Europe, with occasional epidemic visits, such as those of Messina and Marseilles. Now it has left the Levant and Egypt, has abandoned even Mesopotamia and Arabia, and retreated to a few poor villages on the Perso-Armenian frontier. Or, take the example of leprosy, which owed its existence rather to the widespread or national concurrence of the same causes in various countries than to the travelling of an infection: Italy had it first and lost it first, and nearly every other country in Europe saw its rise, its general prevalence, its decline, and its extinction, the northern countries keeping it longest. Again, typhus fever was a standing disease so long as Europe was the theatre of protracted wars and all their consequences; but, like other infections, typhus gradually declined and has almost disappeared since the conditions on which it depended ceased.

Leaving these parallels and coming to the facts of smallpox itself, it rose to prominence in western Europe in the 16th century, and in England in the 17th.[1] From the early part of the 18th century a remission was noted; but the latter half of that century saw a considerable extension of the area of the disease, for which the practice of inoculation has been blamed. It is a mistake to suppose that smallpox has shown a tendency towards a universal infection; for all its chances it has kept within moderate limits of age and place, and extended only by repeated provocation. Thus, Hirsch says of the western hemisphere, "A still more terrible source for America was the importation of Negro slaves, so much so that in after years, particularly in South America and the West Indies, not only the first appearances of smallpox, but every fresh outbreak of it, could be traced to importation from Africa,"—the African continent being then, as now and always, one of its principal native seats. In Europe it has been peculiarly a disease of infancy and of the most crowded parts of cities. It has had victims among the upper classes, just as cholera has had; but, like that disease, its habitat is among the crowded poor; and it would have touched the well-to-do-classes less in former times if there had always been spacious west-end quarters in cities or the modern "passion for clean linen," personal ablutions, and fresh air. Tenement houses and ill-ventilated courts or alleys have been the natural harborage of smallpox; in proportion as these have been demolished the disease has disappeared or been circumscribed in its area. It is fallacious to estimate its prevalence now in ratio of the whole population; for a just comparison of one period with another, we have to take into account, not the death-rate per million living, but the death-rate per million still living under the old-world conditions. From the earliest period of its history in Europe, the disease has had its seasons of quickening or revival, with long intervals of quiescence; only in the most crowded parts of Western cities has it ever been endemic from year to year. These epidemic outbursts have varied much in intensity and in area, the conditions of variation being mostly unknown. In that respect, it need hardly be said, smallpox is like other epidemic diseases.

Influence of vaccination upon smallpox.

During the early years of the 19th century there was a marked remission of the epidemic outbursts of the disease in most parts of Europe. The amount of vaccination during those years was inconsiderable; in particular it hardly touched the poor. Thus, at the time of the Norwich epidemic of 1819, it was estimated (by Cross) that only one-fourth of the inhabitants were vaccinated, and these almost exclusively the well-to-do. At the same time the practice of inoculating smallpox, which was with good reason blamed for keeping the contagion generally diffused and active among the non-inoculated, began to be discontinued and soon ceased altogether. Undoubtedly there was a marked decline in smallpox during the first fifteen years of the century, but the associated circumstances are as complex as the fact itself is simple. We have to bear in mind the old law of periodic exacerbation and dormancy, the cessation of a practice (inoculation) which almost certainly interfered with the natural tendency of smallpox as a foreign pestilence to die out, and the unusual prevalence of typhus fever (on the Continent), and other displacing or substitutive factors in the death-rate. To what extent vaccination was a factor will have to be decided by the experience of a period when the practice was much more generally in vogue. For that purpose we may here restrict the inquiry to England and Wales, premising that the experience of other European countries where vaccination has been equally practiced is not different.

Table III. begins with the year 1847; the registration reports go back to 1838, but there is a break in the tables for five years near the beginning.

In the first years of the table the deaths from smallpox of children under five were to those of all other ages in the ratio of 3 to 1 or of 5 to 2 (at Norwich in 1819 there were 530 deaths, of which half were in infants under two, and all the rest save ten were in children under ten years); the disproportion lessened gradually until about 1864 it was nearly 4 to 3; in 1870 the proportion was nearly equal; and from that time onward the preponderance leaves the age of infancy and childhood, so that in 1884 the deaths under five were three times fewer than those at all other ages. The great epidemic of 1871–72 brought out that remarkable change of incidence most decidedly. Taking the mortality of 1871 as an instance, the significance of the changed incidence on the periods of life is that the 7770 deaths under the age of five would, in pre-compulsion times, have had a complement of no more than 2500 deaths in the latter periods of life, or that the actual mortality of 15,356 above the age of five would have had a complement of some 40,000 or 45,000 deaths below that age. (In British India in 1884 of 333,000 deaths 72 per cent. were of children under 12 in Bengal, and 64 per cent. in Madras.) Apart from the changed incidence of smallpox, Table III. shows merely the caprices of the disease as an epidemic. After every epidemic outburst the disease declines and sometimes looks as if it were about to die out altogether. The alarm attending each severe epidemic has induced the legislature to make the vaccination law more stringent and vaccinators to insert more of the virus, so that the periodic subsidence has corresponded to, and has seemed to be owing to, the better enforcement of the practice; but there have always been alternating periods of quiescence and exacerbation, irrespective of any prophylactic. Moreover, smallpox being a foreign contagious skin disease lurking in congenial haunts, it would be quite according to precedent that it should one day cease absolutely in a community where sanitary progress had advanced so far as to take the ground from under the feet of the pestilence; such absolute cessation would have no more necessary connection with almost universal vaccination than the alternating quiescence and recrudescence of epidemics have been connected with each new Act of Parliament. The epidemic of 1871-72 was one of the worst in the whole history of European smallpox; and it may be that it was one of the last flickers of a slowly expiring flame. The universal practice of cowpoxing, however, is based upon the assumption that this contagious skin disease imported from the tropics is a thing that Europe must reckon with for an indefinite time. On the other hand the teaching of epidemiology is that a foreign pestilence never stays unless it finds quarters suited to its existence, and that it may even take its departure capriciously, as in the case of the plague, after it has had a certain career, or on being displaced by some congener such as typhus. Vaccination is considered to have turned smallpox in great part aside from the early years of life and thrown it more than ever upon the later ages, while measles and other maladies proper to childhood have at the same time increased.[2]

---

[1] The first known use of the term "small pocks" is in Holinshed's *Chronicle* (1577), an epidemic of *pestis* in 1365 being so rendered, although it was probably the ordinary bubo-plague of the period. The pox of Elizabethan writers was the French pox or great pox (syphilis), which overran Europe as an epidemic in 1494. Its prominent character at its first appearance was the loathsome affection of the skin (especially the face); hence when variola came on the scene it was called the lesser pox, or smallpox.

TABLE III.

Deaths from Smallpox from 1847 to 1884, with the numbers among Children under five.

Year.	Total of All Ages.	Children under Five.	All Other Ages.	Year.	Total of All Ages.	Children under Five.	All Other Ages.

Its utility to the individual.

Thus far as regards the utility of vaccination to the state; we have now to consider its utility to the individual. Do the vaccinated escape in an epidemic? or, if they do not escape an attack of smallpox, do they escape death from it? In answer to the first question, apart from the familiar negative experience of everyone, we have the statistics of smallpox hospitals, which relate to the poorer class and probably do full justice to the fact of non-vaccination, inasmuch as the unvaccinated residue is mostly to be found in those slums and tenements of the poor where smallpox (now as always) is apt to linger. At the Eastern Metropolitan Hospital (Homerton) from its opening early in 1871 to the end of 1878 there were 6533 admissions for smallpox, of which 4283 had vaccination marks, 793 had no marks although vaccinated, and 1477 were unvaccinated, giving a proportion of 0.29 unvaccinated. In the epidemic hospitals of Liverpool, Glasgow, and Dublin the proportion was 0.25 during the same period. For some of the German states the proportion of unvaccinated cases comes out a good deal less than one-fourth; thus, in Bavaria, in 1871 of 30,742 cases 29,429 were in vaccinated persons, or 95.7 per cent., and 1313 in the unvaccinated, or 4.3 per cent.[3] In some of the small local outbreaks of recent years the victims have been nearly all vaccinated (*e.g.*, at Bromley in 1881, a total of 43 cases, including sixteen confluent, all vaccinated).[4] In the army and navy, where vaccination and revaccination are absolutely without exception, the proportion is accordingly 0. It would thus appear that the rather excessive proportion of cases among the small residue of unvaccinated in the civil population must have other associated circumstances besides non-vaccination; and these are not far to seek.

Death-rates among vaccinated and unvaccinated.

The next question is the death-rate among the vaccinated and unvaccinated respectively. The total death-rate from smallpox in modern times is almost the same as it was in the 18th century; large aggregates collected by Jurin and others in pre-vaccination times show a mortality of 18.8 per cent., and corresponding aggregates in English and American hospitals, mostly since 1870, show a mortality of 18.5 per cent. It has, however, to be borne in mind that the division into discrete, confluent, and malignant smallpox is an old one; that a mild type was quite common in the 17th and 18th centuries, and was now and then characteristic of whole epidemics, just as in the case of scarlatina; and that the vaccinated are at present liable to be attacked by the confluent and malignant disease as well as by the discrete. But are the vaccinated liable to the fatal forms of smallpox in the same proportion as the unvaccinated? It is only since 1879 that the registrar-general's tables for England and Wales have attempted to supply data bearing on this; and it will be seen from the following abstracts (Tables IV.-VII.) that the data are still far from being sufficient:

TABLE IV.

Deaths from Smallpox, showing the Numbers of the Unvaccinated.

Year.	Total Deaths.	Unvaccinated.	Vaccinated.	Not stated.	Year.	Total Deaths.	Unvaccinated.	Vaccinated.	Not stated.

[1] The Italic numerals indicate the periodic maxima.

[2] See Farr, *Reg. Gen. Report* for 1867, p. 213: "To operate on mortality, protection against every one of the fatal zymotic diseases is required; otherwise the suppression of one disease-element opens the way to another" (p 219). He quotes Watt (1813) to show that the decrease of smallpox mortality among infants in Glasgow from 1783 to 1812 was balanced by a great increase in the infantine deaths from measles. See also Guy, *Journ. Statist. Soc.*, 1882, p. 430.

[3] Majer, *Vierteljahrschrift für gericht. Med.*, xxii. 855.

[4] Nicolson, *Lancet*, 27th August, 1881.

These figures may be made to prove anything, according to the bias of the individual; the column of "not stated" commands the situation. The official figures[1] for Bavaria in 1871 are more precise: among the 29,429 cases of smallpox in vaccinated persons there were 3994 deaths, while among the 1313 unvaccinated cases there were 790 deaths; of the latter no fewer than 743 deaths were of infants in their first year. The mortality among both the vaccinated and the unvaccinated is always excessive for infancy. Feeble health, as well as non-vaccination, is a factor in the very excessive smallpox mortality at that tender age.

The returns from special smallpox hospitals make out a very small death-rate (6 per cent.) among the vaccinated and a very large death-rate (40 to 60 per cent.) among the unvaccinated. The result is doubtful *qua* vaccination, for the reason that in pre-vaccination times the death-rate (18.8 per cent.) was almost the same as it is now in the vaccinated and unvaccinated together (18.5). At the Homerton Hospital from 1871 to 1878 there were admitted 793 cases in which "vaccination is stated to have been performed, but without any evidence of its performance"; the deaths in that important contingent were 216, or 27.2 per cent., but they are not permitted to swell the mortality among the "vaccinated."[2] Again, the explanatory remarks of the medical officer for Birkenhead in 1877 reveal to us the rather surprising fact that his column of "unvaccinated" contained, not only cases that were admittedly not vaccinated, but also those that were "without the faintest mark"; of the 72 cases in that column no fewer than 53 died. His column of "unknown" contained 80 per cent. of patients who protested that they had been vaccinated (28 deaths in 220 cases or 12.7 per cent.). Those who passed muster as veritably vaccinated were 233, of whom 12 died (5.1 per cent.). With reference to this question of the marks, it has to be said that cowpox scars may be temporary, that their "goodness" or "badness" depends chiefly on the texture of the individual's skin and the thickness or thinness of the original crust, and that the aspect of the scar, or even its total absence some years or even months after, may be altogether misleading as to the size and correctness in other respects of the vaccine vesicle, and of the degree of constitutional disturbance that attended it. This was candidly recognized by Ceely,[3] and will not be seriously disputed by anyone who knows something of cowpox and of how it has been mitigated, and of the various ways in which the tissues of individuals may react to an inoculated infection. In confluent cases the marks on the arm would be less easily seen.

The following statistical table (VIII.) shows death from smallpox to be comparatively rare where the marks are many and "good."

TABLE VIII.

Showing the Number and Kind of Arm Marks in 379 Fatal Cases of Smallpox at Homerton Hospital, 1871–80 (Gayton).

Vaccinal Marks.	Admissions.		Deaths.		Mortality pr. ct.

Re-vaccination.

The practice of re-vaccination was first recommended in England by G. Gregory, and in Germany for the army by Heim (1829). It has been more or less the law in Prussia since 1835:[4] "re-vaccination of school pupils at the age of twelve is an integral part of the vaccination law." Notwithstanding the fact that Prussia was the best re-vaccinated country in Europe, its mortality from smallpox in the epidemic of 1871 was higher (69,839) than in any other northern state. The efficacy of re-vaccination is sometimes sought to be proved by the immunity of nurses in smallpox hospitals. The experiment of not re-vaccinating the nurses was tried at the smallpox hospital of the South Dublin Union in 1871–72; 29 out of the 36 attendants had not been re-vaccinated, and these all escaped smallpox as well as the other seven.[5] But nurses are not rarely chosen from among those who have had smallpox, and cases of smallpox in re-vaccinated nurses are not unknown.[6] The evidence as to re-vaccination on a large scale comes from the army. According to a competent statistician (A. Vogt), the death-rate from smallpox in the German army, in which all recruits are re-vaccinated, was 60 per cent. more than among the civil population of the same age; it was ten times greater among the infantry than among the cavalry, and sixty times more among the Hessians than among the Würtembergers. The Bavarian contingent, which was re-vaccinated without exception, had five times the death-rate from smallpox in the epidemic of 1870–71 that the Bavarian civil population of the same ages had, although re-vaccination is not obligatory among the latter.

The susceptibility to cowpox infection diminishes with age; among the pupils of twelve years in Prussian schools it fails in about one-fourth of the attempts, and at later periods of life the proportion of failures is still greater.

It is often alleged that the unvaccinated are so much inflammable material in the midst of the community, and that smallpox begins among them and gathers force so that it sweeps even the vaccinated before it. Inquiry into the facts has shown that at Cologne in 1870 the first unvaccinated person attacked by smallpox was the 174th in order of time, at Bonn the same year the 42d, and at Liegnitz in 1871 the 225th.

Legislation.

State-supported facilities for vaccination began in England in 1808 with the National Vaccine Establishment. In 1840 vaccination fees were made payable out of the rates. The first compulsory act was passed in 1853, the guardians of the poor being entrusted with the carrying out of the law; in 1854 the public vaccinations under one year of age were 408,824, as against an average of 180,960 for several years before. In 1867 a new Act was passed, rather to remove some technical difficulties than to enlarge the scope of the former Act; and in 1871 the Act was passed which compelled the boards of guardians to appoint vaccination officers. The guardians also appoint a public vaccinator, who must be duly qualified to practice medicine, and whose duty it is to vaccinate (for a fee of one shilling and sixpence) any child resident within his district brought to him for that purpose, to examine the same a week after, to give a certificate, and to certify to the vaccination officer the fact of vaccination or of insusceptibility. The Local Government Board awards a considerable sum in premiums for totals of successful vaccination, at a higher scale of one shilling [$.243] for each case, and a lower scale of sixpence. The vaccination officer sees that all infants are vaccinated, either publicly or privately, before they are three months old (in Scotland six months), unless there is reason for postponing the operation. He acts also as registrar of vaccinations. Parents refusing to obey the summons taken out by the vaccination officer are liable to a penalty of twenty shillings [$4.86] for each offence. In 1880 the president of the Local Government Board brought in a bill to repeal the part of the Act relating to cumulative penalties; but the bill was withdrawn owing to protests from the medical profession. In a number of populous unions of England a majority of the guardians are decided not to prosecute under the Vaccination Act; in other unions prosecutions are not unfrequent, the convictions having amounted in 1885 to upwards of two thousand, and having usually led to distraint of goods (rarely to imprisonment) in default of paying the fine. In England about two-thirds of all infants are vaccinated at the public expense.

Vaccination was made compulsory in Bavaria in 1807, and subsequently in the following countries: Denmark (1810), Sweden (1814), Würtemberg, Hesse, and other German states (1818), Prussia (1835), Roumania (1874), Hungary (1876), and Servia (1881). It is compulsory by cantonal law in ten out of the twenty-two Swiss cantons; an attempt to pass a federal compulsory law was defeated by a plebiscite in 1881.

In the following countries there is no compulsory law, but Government facilities and compulsion on various classes more or less directly under Government control, such as soldiers, state employés, apprentices, school pupils, etc.: France, Italy, Spain, Portugal, Belgium, Norway, Austria, Turkey.

In only a few States or cities of the American Union is there a vaccination statute; in Canada there is none. Vaccination has been compulsory in South Australia since 1872, in Victoria since 1874, and in Western Australia since 1878. In Tasmania a compulsory Act was passed in 1882. In New South Wales there is no compulsion, but free facilities for vaccination. Compulsion was adopted at Calcutta in 1880 and since then at eighty other towns of Bengal, at Madras in 1884, and at Bombay and elsewhere in the presidency a few years earlier.

Re-vaccination was made compulsory in Denmark in 1871 and in Roumania in 1874; in Holland it was enacted for all school pupils in 1872. The various laws and administrative orders which had been for many years in force as to vaccination and re-vaccination in the several German states were consolidated in an imperial statute of 1874.

VÁCZ (Germ. *Waitzen*), a market town in Hungary, on the left bank of the Danube, 20 miles north of Buda-Pesth. It gives its name to a Roman Catholic bishopric (established by Stephen, first king of Hungary, in 1000) and various schools, convents, and charities connected therewith, and has a state deaf and dumb institute and a central Government prison. The cathedral, a magnificent structure, is an imitation of St. Peter's at Rome, with mediæval relics and pictures. The majority of the inhabitants are engaged in agriculture and cattle-breeding; but exportation of grapes from the neighboring hilly district is also largely carried on. Vácz is a station on the Austrian-Hungarian railway system. The population, mostly Magyars by nationality, was 13,199 in 1880, and in 1887 was estimated to number nearly 17,000.

VAGA, Perino del (1500–1547), a painter of the Roman school, whose true name was Perino (or Piero) Buonaccorsi. He was born in Florence on 28th June, 1500. His father ruined himself by gambling, and became a soldier in the invading army of Charles VIII. His mother dying when he was but two months old, he was suckled by a she-goat; but shortly afterwards he was taken up by his father's second wife. Perino was first apprenticed to a druggist, but soon passed into the hands of a mediocre painter, Andrea da Ceri, and, when eleven years of age, of Ridolfo Ghirlandajo. Perino rapidly surpassed his fellow-pupils, applying himself especially to the study of Michelangelo's great cartoon. Another mediocre painter, Vaga from Toscanella, undertook to settle the boy in Rome, but first set him to work in Toscanella. Perino, when he at last reached Rome, was utterly poor, and with no clear prospect beyond journey-work for trading decorators. He, however, studied with great severity and spirit from Michelangelo and the antique, and was eventually entrusted with some of the subordinate work undertaken by Raphael in the Vatican. He assisted Giovanni da Udine in the stucco and arabesque decorations of the loggie of the Vatican, and executed some of those small but finely composed Scriptural subjects which go by the name of "Raphael's Bible"—Raphael himself furnishing the designs. Perino's examples are Abraham about to Sacrifice Isaac, Jacob Wrestling with the Angel, Joseph and his Brethren, the Hebrews Crossing the Jordan, the Fall and Capture of Jericho, Joshua Commanding the Sun to Stand Still, the Birth of Christ, His Baptism, and the Last Supper. Some of these are in bronze-tint, while others are in full color. He also painted, after Raphael's drawings, the figures of the planets in the great hall of the Apartamenti Borgia. Perino exhibited very uncommon faculty in these works and was soon regarded as second only to Giulio Romano among the great painter's assistants. To Raphael himself he was always exceedingly respectful and attentive, and the master loved him almost as a son. He executed many other works about Rome, always displaying a certain mixture of the Florentine with the Roman style.

After Raphael's death in 1520 a troublous period ensued for Perino, with a plague which ravaged Rome in 1523, and again with the sack of that city in 1527. Then he accepted an invitation to Genoa, where he was employed in decorating the Doria palace, and rapidly founded a quasi-Roman school of art in the Ligurian city. He ornamented the palace in a style similar to that of Giulio Romano in the Mantuan Palazzo del Tè, and frescoed historical and mythological subjects in the apartments, fanciful and graceful arabesque-work, sculptural and architectural details—in short, whatever came to hand. Among the principal works are the War between the Gods and Giants, Horatius Cocles Defending the Bridge, and the Fortitude of Mutius Scævola. The most important work of all, the Shipwreck of Æneas, is no longer extant. Perino was particularly good in the technique and coloring of fresco, and his stucco-work was no less highly prized than his pictures; his Genoese paintings are, however, very inferior to those of Raphael in finish, as in other higher qualities, and his style in the nude tends rather towards Michelangelo. The Doria work is moreover extremely unequal. From Genoa Perino twice visited Pisa, and began some painting in the cathedral. Finally he returned to Rome, where Paul III. allowed him a regular salary till the painter's death. He retouched many of the works of Raphael, and labored hard on his own account, undertaking all sorts of jobs, important or trivial. Working for any price, he made large gains, but fell into mechanical negligence. Perino was engaged in the general decoration of the Sala Reale, begun by Paul III., when his health, undermined by constant work, and as constant irregularities, gave way, and he fell down dead on 19th October, 1547. He is buried in the Pantheon.

Perino, though his character and habits of life were not such as to inspire respect, seems to have been generally liked in a certain way; he was, however, jealous of rivals, particularly of Titian when in Rome, and grudging in the instruction of his pupils. He produced some excellent portraits, and his smaller oil pictures combine with the manner of Raphael something of that of Andrea del Sarto. Many of his works were engraved, even in his own lifetime. Daniele da Volterra, Girolamo Siciolante da Sermoneta, Luzio Romano, and Marcello Venusti (Mantovano) were among his principal assistants.

VAIR, Guillaume du (1556–1621), one of the fathers of French prose, and at the same time one of the most brilliant ornaments of the great school of French lawyers in the 16th and 17th centuries, was born at Paris on 7th March, 1556. Du Vair was in orders, and, though during the greater part of his life he exercised only legal functions, he in 1617 accepted the see of Lisieux and died bishop thereof. His reputation, however, is that of a lawyer, a statesman, and a man of letters. He was for a considerable time a member (councillor) of the parlement of Paris, and it was in this capacity that he pronounced his most famous politico-legal discourse, an argument nominally for the Salic Law, but in reality directed against the alienation of the crown of France to the Spanish infanta, which was advocated by the extreme Leaguers. It was also during his tenure of the same post that he published (in 1595) a *Traité de l'Eloquence Française*, which both advocates and exhibits a great improvement on the ordinary prose style of the day. In 1599 he became first president of the parlement of Provence (Aix), and in order not to give up this position he refused the see of Marseilles. In 1616 he received the highest promotion open to a French lawyer and became keeper of the seals. His death took place at Tonneins (Lot-et-Garonne) on 3d August, 1621. Both as speaker and writer he holds a very high rank, and his character was equal to his abilities. Like other political lawyers of the time, Du Vair busied himself not a little in the study of philosophy (of a Christian stoical cast) and in that of classical antiquity, translating Cicero, Demosthenes, and Epictetus, and writing various treatises, on which Charron, a general plagiarist, is held to have drawn freely. Du Vair's works were published in folio at Paris in 1641.

VALAIS (Germ., *Wallis*), one of the Swiss cantons, ranking as twentieth in the Confederation. Its name has been explained to mean the "Welsh land," as the Teutons called all non-Teutonic lands; but it is far more probably derived from "vallis," for Valais is simply the "Vallis Pœnina," or valley of the Rhone, from its source to the gorge of St. Maurice, together with some villages south of the Simplon Pass, and Monthey, Val d'Illiez, and Bouveret beyond St. Maurice, on the left bank of the river. The total area of the canton is 2026.3 square miles, which is exceeded only by that of Grisons (Graubünden) and of Bern. Of this 930.4 square miles are classed as productive, forests covering 243.2 and vineyards 9; of the remainder 375.1 square miles consist of snow and ice. The highest point of the canton is Monte Rosa (15,217 feet), and within its borders rises the Dom (14,942 feet), the loftiest peak entirely in Swiss territory. The population in 1880 was 100,216 (males predominating), an increase of 3329 since 1870. French is the native tongue of 67,214 and German of 31,962, the former dwelling (roughly speaking) west and the latter east of a line drawn north and south across the valley of the Rhone between Sierre and Leuk. The bulk (99,316) of the inhabitants are staunch Roman Catholics. The canton forms the diocese of Sion (founded in 4th century), which before 1513 was in the ecclesiastical province of Moutiers-en-Tarentaise (Savoy), and since then has been immediately dependent on the pope. In the canton there are three famous houses of Austin canons regular—St. Maurice (founded as a Benedictine monastery, as distinct from the see, in 515 by Sigismund of Burgundy), the hospice on the Great St. Bernard (first mentioned in 1125), and that on the Simplon Pass (first mentioned in 1235). Ecclesiastical affairs are managed without any control or interference on the part of the state, though the cantonal legislative assembly selects as bishop one of four candidates nominated by the chapter of Sion. The only town of any size is the capital, Sion or Sitten (4871 inhabitants in 1880). The population are mainly engaged in agricultural pursuits, and great efforts have been made to improve matters lately, while the Rhone has been embanked to prevent disastrous floods. Much wine (*e.g.*, Muscat and Vin du Glacier) and a vast quantity of grapes are exported. Education is compulsory and free, but very backward. A railway runs from Brieg to Bouveret. The mineral waters of Leukerbad and Saxon are well known, and in summer the canton is a favorite haunt of tourists.

The Vallis Pœnina was won by the Romans after a great fight at Octodurus (Martigny) in 57 B.C., and was so thoroughly Romanized that the Celtic aboriginal inhabitants and the Teutonic Burgundian invaders (5th cent.) became Romance-speaking peoples. According to a tradition which can be traced back to the middle of the 8th century, the "Theban legion" was martyred at St. Maurice about 285. Valais formed part of the kingdom of Transjurane Burgundy (888), which fell to the empire in 1032, and later of the duchy of Burgundia Minor, which was held from the emperors by the house of Zäringen (extinct 1218). In 999 Rudolph III. of Burgundy gave all temporal rights and privileges to the bishop of Sion, who was later styled "præfect and count of the Valais," and is still a prince of the Holy Roman empire; the pretended donation of Charlemagne is not genuine. The bishops had much to do in keeping back the Zäringen, and later the counts of Savoy. The latter, however, succeeded in winning most of the land west of Sion, while in the upper part of the valley there were many feudal lords (such as the lords of Raron and the counts of Visp). About the middle of the 13th century we find independent communities or "tithings" ("dizains" or "zehnten") growing up. In the same century the upper part of the valley was colonized by Germans from Hasli (Bern), who thoroughly Teutonized it, though many Romance local names still remain. In 1354 the liberties of the seven "tithings" (Sion, Sierre, Leuk, Raron, Visp, Brieg, and Conches) were confirmed by the emperor Charles IV. A little later the influence of Savoy became predominant, and the count secured to his family the bishopric of Sion, of which he was already the suzerain. His progress was resisted by the tithings, which in 1388 utterly defeated the forces of the bishop, the count, and the nobles at Visp, this being a victory of the Teutonic over the Romance element in the land. From 1384 the Morge stream (a little below Sion) was recognized as the boundary between Savoyard or Lower Valais and episcopal or Upper Valais. For the connection of the latter with the Val d'Ossola, see SWITZERLAND, vol. xxii., p. 823. By the election of Walther von Supersax of Conches as bishop in 1457 the Teutonic element finally won the supremacy. On the outbreak of the Burgundian War the bishop of Sion and the tithings made a treaty with Bern. In November of the same year (1475) they seized all Lower Valais up to Martigny, and in 1476 (March), after the victory of Granson, won St. Maurice, Evian, Thonon, and Monthey. The last three districts were given up in 1477, but won again in 1536, though finally by the treaty of 1569 Monthey, Val d'Illiez, and Bouveret alone were permanently annexed to Valais. These conquered districts (or Lower Valais) were always ruled as subject lands by the bishop and tithings of Upper Valais. In 1533 a close alliance was made with the Catholic cantons; but by 1551 the Protestants had won so much ground that toleration was proclaimed by the local assembly. In 1586 Upper Valais became a member of the Golden League, and finally in 1603–4 the four tithings of Conches, Brieg, Visp, and Raron carried the day in favor of the old faith against those of Leuk, Sierre, and Sion. In 1790–91 Lower Valais rose in revolt; but it was not finally freed till 1798, when the whole of Valais became part of the Rhodanic, and then one of the cantons of the Helvetic Republic. Such prolonged and fierce resistance was, however, offered to French rule by the inhabitants that in 1802 Bonaparte declared Valais an independent republic, yet in 1810, for strategic reasons, he incorporated it with France as the "department of the Simplon," and it was not freed till the Austrians came in 1813. In 1815 a local assembly was created, in which each of the seven tithings of Upper and each of the six of Lower Valais (though the latter had nearly double the population of the former) elected four members, the bishop being given four votes. In 1832 Valais joined the League of Sarnen to maintain the Federal Pact of 1815. In 1838–40 it was convulsed by a struggle between the Conservative and Radical parties, the split into two half cantons being only prevented by the arrival of Federal troops. The constitution was revised in 1839 and 1844; the local assembly was to be elected according to population, and the bishop was given a seat instead of his four votes. In 1843 Valais was one of the Sonderbund, and in 1844 civil war raged, many Liberals being slain at the bridge of Trient (May, 1844). The introduction of the Jesuits embittered matters, and Valais was the last canton to submit in the Sonderbund War (1847); it contented itself, however, with voting steadily against the acceptance of the Federal constitutions of 1848 and 1874. By the constitution of 1847 all ecclesiastical immunities were swept away, and the bishop lost his seat in the assembly. That constitution was revised in 1852, and the present one is dated 1875. There is now a legislative assembly of 101 members, elected for four years by all male citizens of twenty years, in the proportion of one member to 1000 inhabitants, and an executive council of five members, holding office for four years, and chosen by the legislative assembly, though in a certain proportion to the different districts of the canton (two for the upper part, one for Sion, two for the lower part). The "financial referendum" exists, by which when a capital expenditure of £2400 [$11,664], or an annual one of £800 [$3888], for three years, is to be incurred, or it is proposed to raise the property tax higher than 1½ per cent., the proposal must be submitted to and approved by a popular vote.

See Furrer, *Gesch. von Wallis* (3 vols., 1852-54); Gingins La Sarra, *Développement de l'Indépendance du Haut Valais et Conquête du Bas Valais* (1844); and J. Gremaud, *Documents Relatifs à l'Histoire du Valais* (1875 *sq.*). (W. A. B. C.)

VALDEPEÑAS, a town of Spain, in the province of Ciudad Real, on the railway line from Madrid to Cordova, is situated in the midst of a district thickly clothed with vineyards at the foot of the northern slope of the Sierra Morena. It is a straggling place and its only industry is that of wine-making (see WINE). The population within the municipal boundaries in 1877 was 13,876.

VALDES, JUAN DE (*c.* 1500–1541), Spanish religious writer, born about 1500 at Cuenca in Castile, was the younger of twin sons of Fernando de Valdes, hereditary regidor of Cuenca. Juan has often been confounded with his twin-brother Alphonso, who was in the suite of Charles V. in 1520, acted as his Latin secretary from 1524, and died in 1532 at Vienna. It has been conjectured that Juan studied at the university of Alcala. We first meet him as the anonymous author of a politico-religious *Diálogo de Mercurio y Caron*, apparently written in 1528 and published then or soon after. As this *Diálogo* reflected strongly on the corruptions of the Roman Church, Valdes got into difficulties with the Spanish Inquisition, and left Spain for Naples in 1530. He removed in 1531 to Rome. On 12th January, 1533, he writes from Bologna, where he was in attendance upon the pope, Clement VII.; his criticisms of papal policy had been condoned, inasmuch as in his *Diálogo* he had defended the validity of the marriage of Catherine of Aragon to Henry VIII. But in the autumn of 1533 he returned to Naples, and seems never to have left it again. His name has been Italianized into Valdesso and Val d'Esso. It has frequently been asserted that he was appointed by Charles V. as secretary to the viceroy at Naples, Don Pedro de Toledo; but of this there is no evidence, and it seems a "harmonizing" conjecture, based on the confusion between Alphonso and Juan. Curione (writing in 1544) calls him "cavalliere di Cesare," but there is no proof of his having ever held an official appointment. At his house on the Chiaja he was the centre of a very distinguished circle, literary and religious, and the influence of his conversations and his writings, chiefly circulated in manuscript, stimulated the desire for a spiritual reformation of the church. The first-fruit of his cultured leisure at Naples was a philological treatise, *Diálogo de la Lengua* (written 1533); but, though his friends urged him to seek distinction by his humanistic studies, his bent was towards the spiritual problems of Biblical interpretation and the deep things of the devout life. Vermigli (Peter Martyr) and Marcantonio Flaminio were leading spirits in the coterie of Valdes, which included Vittoria Colonna and her sister-in-law Giulia Gonzaga. On Ochino, whom he furnished with themes for sermons, his influence was very great. Carnesecchi, who had known Valdes at Rome as "a modest and wellbred courtier," found him at Naples in 1540 "wholly intent upon the study of Holy Scripture," portions of which he translated from the Hebrew and Greek into Spanish, with comments and suggestive prefaces. To his teaching Carnesecchi ascribes his own complete adoption of the Evangelical doctrine of justification by faith, and at the same time his estrangement from the policy of the Lutheran schism. Valdes died at Naples in May, 1541.

The death of Valdes scattered his band of associates. Ochino and Vermigli abandoned the hope of a regenerated Catholicism, and left Italy. By degrees some of Valdes's writings were translated into Italian and published. They exhibit great originality and penetration, combined with a delicate vein of semi-mystical spirituality, and retain a large measure of that personal charm which is attributed to their author in all contemporary notices. Llorente finds traces in Valdes of the influence of Tauler's writings; any such influence must have been at second hand. Valdes was in relations with Fra Benedetto of Mantua, the anonymous author of *Del Benefizio di Gesù Cristo Crocefisso*, which was revised by Flaminio (reprinted by Dr. Babington, Cambridge, 1855). The suggestion that Valdes was unsound on the doctrine of the Trinity was first made in 1567 by the Transylvanian bishop, Francis Dávid (see SOCINUS, vol. xxii. p. 242); it has been adopted by Sand (1684), Wallace (1850), and other anti-Trinitarian writers, and is countenanced by Bayle. Some color has been given to this view by isolated expressions in his writings, and by the subsequent course of Ochino, whose orthodoxy seems, however, to have been unjustly suspected, from the speculative insight with which he presented objections. But Valdes, though he never treats of the Trinity, even when commenting upon Matt. xxviii. 19, reserving it in his *Latte Spirituale* as a topic for advanced Christians, explicitly affirms the consubstantiality of the Son, whom he unites in doxologies with the Father and the Holy Spirit (*Opusc.*, p. 145). His interest centred in matters of practical rather than of speculative theology; his great aim was the promotion of a healthy and personal piety.

The following is a list of his writings.

(1) *Diálogo de Mercurio y Caron*, 8vo (no date or place of printing; 1528?). An Italian translation, by Nicolo Franco, was printed at Venice without date, and reprinted at the same place in 1545. Both with the original and the translation is generally found a *Diálogo* on the sack of Rome in 1527, by Alphonso de Valdes, printed at the same time. Both are ascribed to Juan in the reprint *Dos Diálogos* of 1850. (2) *Diálogo de la Lengua*, written in 1533, first printed at Madrid, 1737, reprinted 1860 and 1873. (3) *Qual Maniera si devrebbe tenere a informare . . . gli Figliuoli de Christiani delle Cose della Religione* (no date or place of printing; before 1545, as it was made use of by the Italian translator of Calvin's catechism, 1545). No Spanish original is known. It was reproduced as *Latte Spirituale*, Basel, 1549, and Paris, 1550. A Latin version, by Pierpaolo Vergerio, was published in 1554 and again in 1557; it has been translated into German twice, into Polish, into English by J. T. Betts, 1882, and into Spanish by Ed. Boehmer, in *Revista Cristiana*, Madrid, February, 1882 (also separately published). (4) *Trataditos*, first published at Bonn, 1881, from a manuscript in the Palatine Library at Vienna. An Italian translation, *I Cinque Tratatelli Evangelici*, was published at Rome, 1545, reprinted 1869. An English translation, by J. T. Betts, is in *XVII. Opuscules*, 1882. (5) *Alfabeto Christiano*, Venice, 1545, an Italian translation of an unpublished and lost Spanish original. An English version, by B. B. Wiffen, was published in 1861. (6) *Çiento i Diez Conçideraçiones;* the original is said to have been published, and all copies suppressed by the Spanish Inquisition; thirty-nine of the *Conçideraçiones* were published with the *Trataditos* from a Vienna manuscript. An Italian translation, by Celio Secondo Curione, *Le Cento et Dieci Divine Considerationi*, was published at Basel, 1550, 8vo. A French translation, by Claude de Kerquifinen, was published at Lyons, 1563, 8vo, and Paris, 1565, 8vo. The English translation by Nicholas Ferrar was published at Oxford, 1638, 4to, at the instance of George Herbert; it was reprinted at Cambridge, 1646; a new translation, by J. T. Betts, was issued in 1865. A translation into Spanish from the Italian, by Luis Usóz i Rio, was published in 1855. (7) *Seven Doctrinal Letters*, printed with the *Trataditos*, from a Vienna manuscript, and translated by J. T. Betts in the *XVII. Opuscules.* (8) *Comentario Breve . . . sobre la Epistola de San Pablo a los Romanos*, Venice, 1556; translation and commentary, edited by Juan Perez de Pineda, reprinted 1856; English version by J. T. Betts, 1883. (9) *Comentario Breve . . . sobre la Primera Epistola de san Pablo a los Corintios*, Venice, 1557; translation and commentary, edited, reprinted, and translated as No. 8. (10) *El Evangelio de San Mateo*, translation and commentary, first published in 1881, from a Vienna manuscript; English version, by J. T. Betts, 1883. (11) *El Salterio*, translation of the Psalms from Hebrew into Spanish, published with the *Trataditos*, from a Vienna manuscript. (12) At Vienna is an unpublished commentary in Spanish on Psalms i.–xli. (13) Sand mentions a commentary on St. John's Gospel, which is not known to exist.

The notices of Valdes in Sand (*Biblioth. Antitrinitar.*, 1684, p. 2), Bayle, and Wallace (*Antitrin. Biog.*, 1850, ii. 8) are very inadequate. The revival of interest in him is due to McCrie, *Hist. Ref in Italy*, 1827, and *Hist. Ref. in Spain*, 1829. But the full knowledge of his life and teachings was first opened up by Benjamin B. Wiffen, whose *Life* of Valdes was prefixed in 1865 to the new translation of the *Considerations*. Since then important discoveries have been made in the Aulic Library, by Dr. Edward Boehmer: compare his *Span. Reformers of Two Centuries*, 1874, and *Lives of the Twin Brothers, J. and A. de Valdes*, prefixed to *Biblioth. Wiffeniana*, 1882, also separately, with introd. by J. T. Betts. For an interesting sketch of Valdes, see Benrath's *Bernardino Ochino*, 1875. Respecting his theological standpoint, compare Bonet-Maury, *Early Sources of Eng. Unit. Christianity*, trans. by Hall, 1884. (A. GO.)

VALDO. See WALDO.

VALENCE, a town of France, chef-lieu of the department of Drôme and an episcopal see, is situated on the left bank of the Rhone, 65 miles south of Lyons on the railway to Marseilles. The river is here crossed by a fine suspension bridge. The cathedral of St.

Apollinaris (originally of St. Stephen) was rebuilt in the 11th century in the Auvergnesque variety of the Romanesque style, and consecrated in 1095 by Urban II. It was greatly injured in the Wars of Religion, but restored in 1604. The porch was rebuilt in 1861; above it rises a stone tower (187 feet). The church contains the monument of Pius VI. (bust by Canova), who died at Valence in 1799. A curious house (Les Têtes) of the 16th century has a sculptured front with heads of Homer, Hippocrates, Aristotle, Pythagoras, etc. The antique "little seminary" is occupied by a gallery of pictures, a museum of natural history, a library (25,000 volumes), and a collection of antiquities. Valence possesses a botanical garden, a champ de Mars, artillery barracks, and a departmental prison, worked on the solitary system. The chief industries are the spinning and weaving of silk, oil-pressing, distilling, metal-founding, and the manufacture of macaroni. A considerable trade is carried on in the product of this industry and in wine and agricultural produce. The population in 1881 was 21,941 (commune 25,402) and in 1886 22,453 (commune 24,761).

Valentia colonia Julia, Valentia Segalaunorum urbs, or *civitas Valentinorum*, was the capital of the Segalauni, and the seat of a celebrated school prior to the Roman conquest, a colony under Augustus, and an important town of *Viennensis Prima* under Valentinian. It was ravaged by the Alani and other barbarians, and fell successively under the power of the Burgundians, the Franks, the sovereigns of Arles, the emperors of Germany, the dukes of Valentinois, the counts of Toulouse, and its own bishops. The inhabitants rose unsuccessfully against these last in 1229, but obtained protection with the help of the dauphin in 1345. In 1450 they had their rights and privileges confirmed by Louis XI. and put on an equal footing with those of the rest of Dauphiné. In the 16th century Protestantism spread freely under Bishop Jean de Montluc, and Valence became the capital of the Protestants of the province in 1563. The town was fortified by Francis I. It had become the seat of a celebrated university in 1454; but the revocation of the Edict of Nantes struck a fatal blow at its industry, commerce, and population. Valence was the birthplace of General Championnet and of President Bonjean (shot by the Commune of Paris in 1871); the family of Montalivet had its origin here.

VALENCIA, a province of Spain, one of the three into which the former "kingdom" of Valencia is now divided, has an area of 4352 square miles and a population (1877) of 679,030, being thus, next to Barcelona, the most populous province in the kingdom. It is bounded on the N. by Teruel and Castellon de la Plana, on the E. by the Mediterranean, on the S. by Alicante, and on the W. by Albacete and Cuenca. The surface is very much diversified; along the coast it is for the most part low and level, the fertile "vegas" of Valencia, Játiva, and Gandia in many places rising very little above sea-level; to the west of these is a series of tablelands of a mean elevation of about 1000 feet, which in turn rise into the mountains that form the eastern boundary of the tableland of New Castile, and attain within the province a maximum elevation of nearly 4000 feet. The principal rivers are the Guadalaviar or Turia and the Jucar. The former enters the province in the extreme northwest, flows southeast, and falls into the sea below the town of Valencia; it receives numerous tributaries of little importance, and it dispenses fertility by numerous "acequias," mostly of Moorish origin, throughout the whole of the lower part of its course. The Jucar is joined on the left at Cofrentes ("Confluentes") by the Cabriel, a stream nearly as considerable as itself, and lower down by the Magro; its chief right-hand tributary is the Albayda. Both the Jucar and the Albayda, like the Turia, supply an extensive irrigation. Almost every kind of geological formation from the Silurian to the Quaternary is represented in Valencia: the vegas are Quaternary; nearly three-fourths of the entire province belongs to the Cretaceous; large areas, especially to the west, in the district of Requena and Utiel, are of the Tertiary period; in the north the Jurassic is prominent; and Triassic is found along many of the river-valleys. The coast is skirted by considerable stretches of sand dune, and by a series of these the lagoon of Albufera (21,000 acres) is separated from the Mediterranean. The vegas enjoy an exceptionally fine, almost sub-tropical climate. In their low-lying portions rice is the favorite crop; elsewhere wheat, maize, and all kinds of fruit are abundantly grown; the mulberry is cultivated for silk; and wine and oil are produced. Esparto grass is grown in the less fertile areas. The tablelands produce according to their elevation and exposure figs, almonds, olives, and vines. The pastures of the higher grounds sustain numerous sheep and goats; but cattle and horses are relatively few in Valencia. The hillsides are somewhat bare of timber. The mineral resources of the province are little developed. The fishing industry on the coast is considerable. The manufactures include those of silk, glass, pottery, and leather; there are also iron foundries, distilleries, and soap manufactories. The coast railway from Tarragona to Encina passes through Valencia, whence another line has been carried along the Cuenca road as far as to Utiel (54½ miles). The province is divided into twenty-one partidos judiciales and has 275 ayuntamientos. There are six "cities"—Valencia (see below), Gandia (7604 inhabitants in 1877), Játiva (14,534), Requena (13,527), Sagunto (6287), and Alcira (16,146).

VALENCIA, capital of the above province, is situated in the beautiful "huerta" of Valencia, on the right bank of the Guadalaviar or Turia, 3 miles above its mouth, and 304[1] miles by rail east-southeast from Madrid. Until 1871 it was enclosed by a wall, built in 1356 by Pedro IV.; two picturesque gateways with machicolated towers still remain. The river, reduced, except in time of flood, to a scanty stream by the demands made upon it for purposes of irrigation, is crossed by five bridges, of which the longest has thirteen arches. The streets are for the most part narrow, crooked and somewhat gloomy, but in the more modern quarters there are some broad and handsome thoroughfares. The cathedral (La Seo), begun in 1262, was afterwards (1459) lengthened in its original Gothic style, but in such a way as to spoil its proportions, and in the 18th century it was further injured by Pseudo-Classic additions. It possesses some fine examples of the sculpture and metal-work of the 15th century, as well as of the Valencian school of painting. The campanile (El Miguelete), an isolated octagonal Gothic tower, 162 feet in height, commands an extensive view of the town and surrounding country. Near the cathedral is the episcopal palace; its large and valuable library, rich in medals and other antiquities, suffered greatly during the French occupation in 1812. Besides the cathedral, Valencia has fourteen parish churches and numerous other ecclesiastical buildings, none of them of great architectural beauty or interest; the church of St. Nicholas (of Moorish origin) has, however, good specimens of Juanes as well as frescos by Dinis Vidal; and Ribalta can be studied in the chapel of the Colegio de Corpus or del Patriarcha. The university buildings, dating from the 16th century, are large but uninteresting; the library (about 42,000 volumes) suffered severely in 1812, and, like the other appointments of the university, falls considerably short of modern requirements.[2] There is a collection of pictures (about 1000) in the city gallery, but only a few—almost entirely of the local school—are of any importance. Among other public buildings may be mentioned the court-house, a Doric edifice, dating from the time of Ferdinand the Catholic, and having curious frescos (1592) in its "chamber of deputies"; the custom-house (1758), now a cigar manufactory, employing some 3500 women; and the silk exchange, a large and elegant Gothic hall (1482). The citadel, on the northeast of the town, was built by Charles V. as a protection against Barbarossa, the sea-rover; in the southwest of the town is the former College of Saint Augustine, now used as a model prison, adjoining which is a large hospital. Outside the walls are a botanic garden, a large bull-ring, and various shady promenades, including the beautiful "Glorieta," and, on the north side of the river, the alameda, leading to the port of El Grao. The principal manufacture is silk, and the town is also celebrated for its colored tiles or "azulejos." Linen and woollen fabrics, hats, leather, paper, cigars, glass, and pottery are also manufactured, and there are foundries and printing-works. Corn, rice, silk, saffron, oranges, raisins, almonds, figs, and other fruits are extensively exported, and iron, hardware, timber, and colonial produce are imported. The port is at El Grao (Villanueva del Grao; population 4433 in 1877), 3 miles distant, where a commodious harbor with a minimum depth of 20 feet has been constructed. The works were begun in 1792. The population of Valencia in 1877 was 143,856, and in 1888 about 170,000 (estimated).

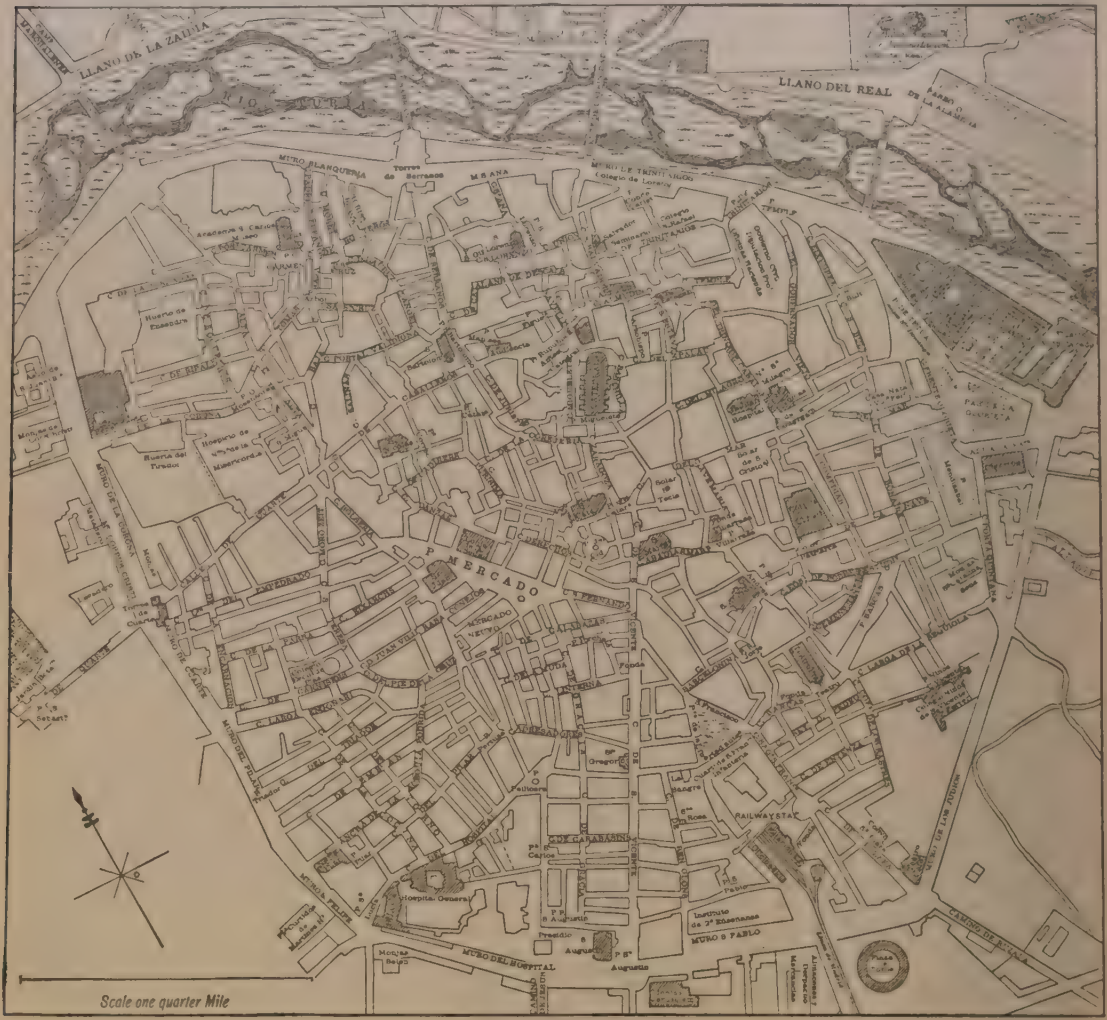
[2] [The first printing press in Spain was probably set up in Valencia in 1474.—Am. Ed.]



Plan of Valencia.

The earliest historical mention of Valencia (*Valentia*) is by Livy (*Epit.*, lv.), according to whom Junius Brutus settled the soldiers of Viriathus here (136 B.C.). It sided with Sertorius (*c.* 77 B.C.) and was accordingly severely punished by Pompey, but must have recovered speedily, being mentioned by Pliny (iii. 4) as a colony in the region of the Edetani, and spoken of by Mela as an important place. It was taken from the Goths by the Moors in 714, and from the Moors by the Cid (see vol. v. p. 676) in 1094, from whom it is sometimes called Valencia del Cid. The Moors recovered possession in 1101, but were compelled finally to relinquish it in 1238, when Jayme I. of Aragon ("El Conquistador") added it to his dominions.[1] In the 16th and 17th centuries it became the seat of a considerable school of painting, of which Juanes (1506–79) may be regarded as the founder, and to which belonged also Francisco de Ribalta (1550–1628) Juan de Ribalta (1597–1628), José Ribera (1588–1656), Pedro Orrente (1560–1644), and J. G. Espinosa (1600–1680). In the beginning of the 17th century Valencia and its surrounding district suffered greatly from the expulsion of the Moors, its most industrious and enterprising cultivators. In the War of Succession Valencia sided emphatically with the house of Austria, for which it was punished by being deprived of many of its ancient privileges. In 1808 an abortive attempt to capture it was made by the French; they succeeded, however, in 1812, and held it till June, 1813.[1]

VALENCIA, a town in the United States of Venezuela, capital of the state of Carabobo, situated amidst savannas and tropical plantations, 1800 feet above sea-level, in the valley between the two chains of the Maritime Andes. It is about 3 or 4 miles distant from the Lagoon of Tacarigua or Lake of Valencia (about 45 miles in length and from 10 to

---

[1] [There are several other Valencias in Spain, as V. de Alcantara, V. del Ventosa, V. Don Juan.—AM. ED.]

13 in width). The town is connected by cart-roads with Carácas and other places in the interior, as well as with its port, Puerto Cabello. A railway across the northern chain of the Maritime Andes, with a total length of 33½ miles, was nearly completed between Valencia and its seaport in the end of 1887. The town is well built, with straight streets cutting one another at right angles. The *plaza* or chief square, which is adorned with an early Spanish church, commands a magnificent view of the Maritime Andes. There are several manufactories, among them a weaving factory and one for the making of machinery and agricultural implements. An iron aqueduct supplies the town with drinking water. Among the educational institutions are a college of science and a normal school. The climate is said to be healthy. The highest temperature is equal to 85° Fahr., the lowest 68°, the mean 76.5°. The population in 1883 was 36,145.

VALENCIENNES, a town of France and a first-class fortress, in the department of Nord, is 157 miles north-northeast of Paris on the railway to Brussels, at the point where the river Rhonelle joins the Scheldt. The latter here divides into two branches, one of which flows through the town, while the other, canalized, fills the trenches of the citadel and skirts the fortifications. Valenciennes is the centre of a rich coal-field, which has called into existence numerous foundries, forges, rolling-mills, wire-works and machine shops. There is also an extensive beet root cultivation, with attendant sugar-works and distilleries. Cambrics and lawns are manufactured and calico-printing is carried on, though little of the famous lace is now made. There are a court of first instance, a chamber of commerce, a conseil de prud'hommes, a chamber of agriculture, and a sugar exchange. The town-hall, rebuilt after the old plan in 1867–68, and surmounted by a square campanile, contains examples of the three Watteaus, Van Dyck, Velazquez, Rubens (the stoning of St. Stephen), as well as numerous productions of the native school of fine arts (founded in 1782). There are also collections of medals and seals and a fine specimen of old Valenciennes tapestry. The library, formed at the Revolution from the libraries of the religious houses of Valenciennes, St. Amand, and the neighborhood, contains 25,000 printed volumes and 980 MSS., the latter including valuable works in early Romance. Valenciennes also contains several interesting private collections, and has associations for the promotion of agriculture, science, art, music, etc. The church of Notre Dame du Cordon, of the 13th century style, was consecrated in 1864. The church of St. Géry has a graceful modern tower; but only a few pillars remain of the old building of 1225. The crooked and ill-paved streets contain some houses of the 15th and 16th centuries. Statues of Watteau and Froissart adorn the town. Of the six gates three have some architectural pretensions. The population in 1881 was 23,291 (commune 27,607) and in 1886; 22,919 (commune 27,575).

Valenciennes, so named because founded or restored by the emperor Valentinian I., was a residence of Clovis, and it was hither that Charlemagne summoned his first assembly of states in 771. The Normans were repulsed from its fortifications in 881. Valenciennes by turns belonged to Hainault and was independent, till taken by Baldwin of Flanders in 1003. It espoused the cause of Jean d'Avesnes in 1353, and was unsuccessfully besieged by the Flemings. In the 16th century Valenciennes became the stronghold of Protestantism in Hainault, but was conquered by the Spaniards, who committed all sorts of excesses. In 1656 the Spaniards under Condé made a successful defence against the French under Turenne; but in 1677 Louis XIV. took the town after an eight days' siege, and Vauban constructed the citadel. Valenciennes has since always belonged to France. In 1793, after forty-three days' bombardment, the garrison, reduced to 3000 men, surrendered to the allied forces numbering some 140,000 or 150,000 men, with 400 cannon. In 1815 it defended itself successfully. Among the natives of Valenciennes may be mentioned Isabella of Hainault, wife of Philip Augustus of France, Baldwin IX. of Flanders (emperor of Constantinople), Jeanne of Flanders, Henry VII. of Luxemburg (emperor of Germany), Froissart, the painters Watteau (3), Pater and Abel de Pujol, the sculptors De Crauck, Durez, Saly, Carpeaux and Lemaire, the soldiers Jacques de Lalaing and Charles de Lannoy (viceroy of Naples), and the navigator Lemaire.

VALENS, emperor of the East from 364 to 378, owed his elevation in the thirty-sixth year of his age to his brother Valentinian, who chose him to be his associate in the empire, of which a formal division into East and West was now once for all definitely arranged (see VALENTINIAN I.). Valens had been attached to Julian's bodyguard, but he was not much of a soldier, though his father, Gratian of Pannonia, had risen from the ranks to a high position. A revolt headed by Procopius in the second year of his reign, and backed up by the public opinion of Constantinople and the sympathy of the Gothic princes and chiefs on the Danube, seemed so alarming that he thought of negotiation; but in the following year the revolt collapsed at the prompt action of a loyal and able veteran officer. In the year 366 Valens at one stroke reduced the taxes of the empire by one-fourth, a very popular measure, though one of questionable policy in the face of the threatening attitude of the Goths on the lower Danube. Before venturing on a campaign against them, Valens received baptism from Eudoxus, the bishop of Constantinople and the leader of the Arian party. After some small successes over the Goths, won by his generals, Valens concluded a peace with them, which lasted six years, on a general understanding that the Danube was to be the boundary between Goths and Romans. On his return to Constantinople in 369–70 Valens began to persecute his orthodox and Catholic subjects. Yet he can hardly have been a hearty and willing persecutor, or he would not have suffered the orthodox Basil to remain bishop of Cæsarea in Cappadocia, nor can he have been a thoroughgoing religious fanatic, or he would not have restrained many of his subjects from burying themselves in monasteries to escape the duties of citizens. Indeed he had not the strength of will or force of character to have been either the one or the other.

In the years 371 to 377 Valens was in Asia Minor, most of the time at the Syrian Antioch. The late war with Persia under the emperors Julian and Jovian had not been satisfactorily concluded: the question as to the possession of the protectorate of Armenia was still in suspense. Valens, though anxious to avoid an Eastern war, because of danger nearer home from the restlessness of the Goths, was compelled to take the field against Sapor, who had invaded and occupied Armenia. It seems that Valens[1] crossed the Euphrates in 373, and in Mesopotamia his troops drove back the king of Persia to the farther bank of the Tigris. But the Roman success was by no means decisive, and no definite understanding as to boundaries was come to with Persia. Valens returned to Antioch, where in the winter of 373 a young man of high rank, Theodorus by name, was made to believe by a pack of fortune tellers and magicians that the emperor's successor would be a man whose name began with "Theod." Theodorus was put to death, with many others whose name began with the same fatal letters; and this led to a vindictive persecution throughout the province of Asia of all who professed or practiced magic and necromancy. The age was a very superstitious and inquisitive one, and Valens certainly shared its weakness. Between 374 and 377 we read of grievous complaints of injustice and extortion perpetrated under legal forms, the result probably of the recent panic, and pointing to an increasing weakness and timidity at headquarters. Although preparations were made for following up the war with Persia and securing the frontier, a truce was patched up, rather to the disadvantage of the empire, Armenia and the adjacent country being half conquered and annexed by Sapor. The armies of Rome, in fact, were wanted in another quarter. The Huns, of whom we now hear for the first time, were beginning in 376 to press the Goths from the north, and the latter asked leave of the emperor to cross the Danube into Roman territory. This they were allowed to do, on the condition that they came unarmed, and their children were transported to Asia as hostages. The conditions, however, were not strictly enforced, and the whole affair was treacherously mismanaged by the imperial generals, who for their own profit forced the new settlers to buy food at famine prices. Accordingly, the enraged Goths, under their chief, Frithigern, streamed across the Balkans into Thrace and the country round Adrianople, plundering, burning and slaughtering as they went. They were driven back for a time, but returned in the spring of 378 in greater force with Huns and Alans to fight with them against the empire; and again, after one or two repulses, they penetrated to the neighborhood of Adrianople. Valens, who had now returned to Constantinople, left the capital in May, 378, with a strong and well-officered army. Without awaiting the arrival of his nephew, Gratian, emperor of the West, who had just won a great victory over one of the barbarous tribes of Germany in Alsace, Valens attacked the enemy at once, although his troops had to go into action heated and fatigued by a long march on a sultry August day. The battle was decided mainly by the cavalry of the Alans and Sarmatians, the Roman infantry being outnumbered, outmanœuvred, and finally so hemmed in that the men could scarcely draw their swords. The slaughter went on for hours, till the imperial army was destroyed. Valens either perished on the field or, as some said, in a cottage fired by the enemy. From the battle of Adrianople the Goths permanently established themselves south of the Danube.

---

[1] Amm. Marc., xxix. 1; the narrative is brief and not very clear.

Ammianus Marcellinus, a contemporary writer, is our chief authority for the reigns of Valens and Valentinian. See also Gibbon's sketch of the period in the 26th and 27th chapters of his *Decline and Fall* and Hodgkin's *Italy and her Invaders*.

VALENTINE, or **VALENTINUS**, the name of a considerable number of saints,[1] three of whom may be particularized. 1. VALENTINUS, presbyter and martyr, according to the authorized Roman legend (see lesson for second nocturn, 14th February, in the diocese of Tortosa), was arrested and thrown into chains at the instance of the emperor Claudius (Gothicus), and handed over to Calphurnius, who employed one Asterius to try to win him back to idolatry. Valentine miraculously healed the blind daughter of Asterius, who accordingly believed and was baptized, with all his house. The saint after long imprisonment was beaten with clubs and finally beheaded on the Flaminian Way (14th February). 2. VALENTINUS of Interamna (Terni), bishop and martyr, miraculously healed Chæremon, the deformed son of Craton, a Greek rhetorician living in Rome, who along with various other prominent persons was accordingly converted. This Valentine, who also is commemorated on 14th February, is invoked, especially in Italy and Germany (St. Velten), in cases of epilepsy and cognate disorders. 3. VALENTINUS, who is spoken of as the apostle of Rhætia, and venerated in Passau as its first bishop, flourished during the first half of the fifth century.

For the peculiar observances that used to be connected with St. Valentine's Eve and Day in England, Scotland, and also (it is said) in some parts of France, and to which allusion is so frequently made by English writers from Shakespeare onwards, such works as Brand's *Popular Antiquities*, Hone's *Every-Day Book*, or Chambers's *Book of Days*, may be consulted. Their appropriateness to the spring season is, in a general way, perhaps, obvious enough; and, as for the name, it has been suggested that there is at least a similarity in sound between Valentine and *galentin* (Fr. dim. from *galant*).

VALENTINIAN I., emperor of the West from 364 to 375. He had been an officer of the guard under Julian and Jovian, and had risen high in the imperial service. With a fine robust frame, he possessed great courage and great military capacity. He was chosen emperor in his forty-third year by the officers of the army at Nicæa in Bithynia early in 364, and shortly afterwards named his brother VALENS (*q.v.*) colleague with him in the empire. The two brothers, after passing through the chief cities of the neighboring district, arranged the partition of the empire at Naissus (Nissa) in Upper Mœsia. As emperor of the West, Valentinian took Italy, Illyricum, Spain, the Gauls, Britain, and Africa, leaving to Valens the eastern half of the Balkan Peninsula, Greece, Egypt, Syria, and Asia Minor as far as Persia. During the short reign of Valentinian there were wars in Africa, in Germany, and in Britain, and Rome came into collision with barbarian peoples of whom we now hear for the first time,—Burgundians, Saxons, Alemanni. The emperor's chief work was guarding the frontiers and establishing military positions. Milan was at first his headquarters for settling the affairs of northern Italy; next year (365) he was at Paris, and then at Rheims, to direct the operations of his generals against the Alemanni. This people were driven back to the German bank of the Rhine, and checked for a while by a chain of military posts and fortresses, though at the close of 367 they swooped down on Moguntiacum (Mainz) and plundered the city. In that same year Valentinian was at Amiens, and there, before his assembled troops, he gave the title of Augustus to his son Gratian, eight years of age. The next three years he spent at Treves, organizing the defence of the Rhine frontier against the Alemanni and Saxons, and personally superintending the construction of numerous forts. Treves was, in fact, his headquarters during most of his reign. His general administration seems to have been thoroughly honest and able, in some respects beneficent. If he was hard and exacting in the matter of taxes, he spent them in the defence and improvement of his dominions, not in idle show or luxury. Though himself a plain and almost illiterate soldier, he was a founder of schools, and he also provided medical attendance for the poor of Rome, by appointing a physician for each of the fourteen districts of the city. He was a Christian, an orthodox Catholic, and in his life perfectly pure; but he permitted absolute religious freedom to all his subjects. Against all abuses, both civil and ecclesiastical, he steadily set his face, even against the increasing wealth and worldliness of the clergy. Valentinian was in many ways a good and able ruler at a particularly difficult time. The great blot on his memory is his cruelty, which at times was frightful, and showed itself in its full fierceness in the punishment of persons accused of witchcraft, soothsaying, or magical practices. In 374 the Quadi, a German tribe in what is now Moravia and Hungary, resenting the erection of Roman forts to the north of the Danube in what they considered to be their own territory, crossed the river and laid waste the province of Pannonia, Valentinian's native land. The emperor in the April of the following year entered Illyricum with a powerful army, and gave audience to an embassy from the Quadi at Bregetio on the Danube, somewhere near Pressburg. Their defence threw him into a paroxysm of rage, in which he suddenly fell down, apparently in a fit of apoplexy, and died in a few hours. His two sons, Gratian and Valentinian II., were jointly his successors.

VALENTINIAN II., an infant of four years of age, with his half-brother Gratian, a lad of about seventeen, became the emperors of the West on the death of their father, Valentinian I., in 375. They made Milan their home: and the empire was nominally divided between them. Gratian taking the trans-Alpine provinces, whilst Italy, Illyricum in part, and Africa were to be under the rule of Valentinian II., or rather of his mother, Justina. Justina was an Arian, and the imperial court at Milan pitted itself against the Catholics, under the famous Ambrose, bishop of that city. But so great was his popularity that the court was decidedly worsted in the contest, and the emperor's authority materially shaken. In 387 Maximus, who had commanded a Roman army in Britain, and had in 383 (the year of Gratian's death) made himself master of the northern provinces, crossed the Alps into the valley of the Po and threatened Milan. The emperor and his mother fled to Thessalonica, to Theodosius, the emperor of the East and husband of Galla, Valentinian's sister. At their entreaty he marched into Italy with an army, decisively defeated Maximus, and set Valentinian once more on the throne (388). He also converted the lad to orthodox Catholicism. Four years later Valentinian was dead. A barbarian warrior, a Frank named Arbogast, who had fought for Gratian and Theodosius, so presumed on his services that Valentinian was provoked into giving him a letter of dismissal. But Arbogast tore the letter up before the emperor's face and openly defied him. Soon afterwards Valentinian was slain, no doubt by Arbogast's order, at Vienne in Gaul, while taking part in some athletic sports. Eugenius, a humble dependent of the barbarian, succeeded to the empire of the West, a disgrace noted by the poet Claudian (*De Tertio Consulatu Honorii*, lxvi.).

---

[1] The *Heiligenlexicon* of Stadler-Ginal enumerates fifty two.

VALENTINIAN III., emperor of the West from 425 to 455, the son of Constantius and Placidia, daughter of the great Theodosius, was declared Cæsar at Thessalonica under the auspices of Theodosius II., and again the following year at Rome, in the seventh year of his age. His reign of thirty years was a period of great and terrible events associated with the names of Attila, Genseric, and Aetius, the "last of the Romans." This period is marked by the dismemberment of the Western empire, the conquest of the province of Africa by the Vandals in 439, the final abandonment of Britain in 446, the loss of great portions of Spain and Gaul, in which the barbarians had established themselves, and the ravaging of Sicily and of the western coasts of the Mediterranean by the fleets of Genseric. As a set-off against these calamities there was the great victory of Aetius over Attila in 451 in the neighborhood of Châlons. (See ROME, vol. xx., p. 799.) The burden of taxation became more and more intolerable as the power of Rome decreased, although there were a partial remission of taxes in 450 and a cancelling of arrears in consequence of the general impoverishment of Rome's subjects. Ravenna was Valentinian's usual residence; but he fled to Rome in 452 on the approach of Attila, who, after ravaging the north of Italy, died in the following year. In 454 Aetius, between whose son and a daughter of the emperor a marriage had been arranged, was treacherously murdered by Valentinian. Next year, however, the crime was avenged by the assassination of the emperor as he was looking on at some games in the Campus Martius. He was a contemptible creature, cowardly, self indulgent, without spirit, and without ability. With Valentinian III. the family of Theodosius became extinct.

Our chief original sources for the reign of Valentinian III. are Jordanes, Prosper's *Chronicles*, written in the 6th century and ending with the year 455, and the poet Sidonius Apollinaris. See also Gibbon's history of the period (*Decline and Fall*, c. xxxiii.-xxxv.) and Hodgkin's *Italy and her Invaders* (1880).

VALENTINUS AND VALENTINIANS. Valentinus was the most important Christian theologian before Origen. Clement and Origen both were his pupils. In his school all those problems were started which afterwards engrossed the Greek fathers, and a large proportion of the solutions given by him and his followers subsequently became, though in a modified form, accepted doctrines. The dogmatic of Origen lies at the foundation of the orthodox dogmatic of the church, and it in its turn had its prototype in that of the Valentinian school. Valentinus was the first man in Christendom who for other than merely apologetic purposes sought to fuse together the results of Greek philosophy with the substance of the Gospel, combined the exalted ethic of the Platonic and Neopythagorean schools with the preaching of the evangelical pulpit, and treated the manifestation of Jesus as the keystone in the great structure of thought which Greek science had reared. His theology is, so to speak, the central pier of the bridge connecting the Jewish with the Christian Alexandrians. He may perhaps be regarded as superior to Philo in sobermindedness and in acuteness, and as having excelled Origen at once in delicacy of religious and moral perception and in vigor of language, though he was far behind him in learning and in extent of knowledge.[1] His success as a teacher was brilliant. Tertullian tells us that among all the Christian "collegia" that of Valentinus was the most crowded,[2] and the numerous branches into which his scholars soon divided are evidence of the wealth of his influence. Even his enemies have praised his "ingenium et eloquium" (*Adv. Valent.*, 4). Tertullian, Clement, Origen, Jerome, and Adamantius agree in testifying that he was a man of singular gifts. The few extant fragments of his writings fully confirm this: there is not one of them that is not marked by originality and depth. And his disciples, although they have partly deteriorated his teachings by undisciplined fancies and inappropriate mythologizing, have, every one of them, something particular and valuable to say. Their influence did not cease until in the catechetical school of Alexandria the church found teachers of her own who were at once scientific theologians and defenders of the church of orthodoxy.

Valentinus.—Of Valentinus himself almost nothing is known. That he was an Egyptian by birth and received his education in Alexandria is probable but not certain.[3] He came to Rome under Hyginus about 138, flourished under Pius (140–155), and was still there in the time of Anicetus (*c.* 155–166). This we learn from Irenæus (iii. 4, 3), who lets us see that his main activity was in Rome. He further tells us that Polycarp during his sojourn in that city was the means of converting some Valentinians. Tertullian supplements (*De Præscr.*, 30) Irenæus with the information that Valentinus originally attached himself in Rome to the main body of the church, but "ob inquietam semper curiositatem qua fratres quoque vitiabat," after having been twice temporarily suspended from communion, he was ultimately cut off. This statement shows that the Roman Church did not, to begin with, possess the standards by which to try Valentinus. The sections of the *Shepherd* of Hermas which treat of the Gnostics represent them as still continuing to exist within the church, although their dangerous character was already known. It was not, then, until the bishopric of Anicetus that the Roman Church succeeded in ridding itself of the Valentinian collegia. It seems very doubtful whether there is any good foundation for Tertullian's further allegation (*Adv. Valent.*, 4) that Valentinus was ambitious of obtaining the episcopate of Rome and that his failure in this caused him to break with the church. Hippolytus will have it (see Epiphanius and Philaster) that Valentinus afterwards went to Cyprus as a declared heretic. We are not in a position to controvert this statement; but the words of Irenæus would almost lead to the conclusion that he died in Rome. At any rate there is no reason to suppose that he was alive much later than 160. Tertullian, in spite of a disposition to bring him down to as recent a period as possible, does not seem to think of him as living in the time of Marcus Aurelius. But in the school of Valentinus it was asserted that their master had been a pupil of Theodas, a *γνώριμος Παύλου*;[1] in that case he must have been a very old man in 160.

---

[1] Jerome nevertheless calls him "doctissimus" (*Comm. in Osee*, ii. 10).

[2] Tert., *Adv. Valent.*; *cf.* Origen, *Hom.*, ii. 5, and *Comm.*, xiv. p. 40, "robustissima secta."

[3] Epiph., *Hær.*, 31; *Mur. Fragm.*, *fin.*

Valentinus was the author of several epistles, three fragments of which have been preserved by Clement;[2] one of these was addressed to a certain Agathopus. He also composed homilies (one entitled *On Friends*), of which we possess four fragments.[3] An expression of Tertullian's (*Adv. Valent.*, 2) seems to imply that Valentinus was also the author of a treatise entitled *Sophia*. Perhaps this is the source from which Irenæus's systematic account of the Valentinian doctrine (i. 11, 1) was indirectly taken. Tertullian speaks of *Psalms* of Valentinus (*De Car.*, xvii. 20); the author of the *Muratorian Fragment* seems also to refer to these; and in the *Philosophumena* of Hippolytus (vi. 37) a considerable fragment from them is given. The "gospel" of Valentinus is spoken of below.

Sources.—All that we possess of Valentinus and his disciples are the fragments preserved by their opponents, the fathers of the church. We cannot therefore put implicit confidence in all that they tell us, or accept as of primary importance in the doctrine of the Valentinians all that they represent as such. The extant fragments of the writings of Valentinus himself, as well as of those of his scholars (Ptolemæus, Heracleon, Theodotus, and others), fortunately enable us to set their theology in a more worthy light than does the fantastic "system" which Irenæus has given. Of the four ancient treatises against the Valentinians known to Tertullian we possess but one, that of Irenæus, those of Justin, Miltiades, and Proculus being lost. The loss of Justin is most to be regretted, for he was a contemporary, and wrote his *Syntagma* probably in Rome at the time when Valentinus was actually laboring there. In Rome some sixty years later the author of the *Muratorian Fragment* also took notice of him. Proculus wrote a special polemic against him, while Miltiades wrote in the same sense in Asia Minor and Irenæus in Gaul about 180. Tertullian's *Adversus Valentinianos* was composed in Carthage some twenty years later, and Clement engaged in a work of a similar nature almost simultaneously at Alexandria. Against the Marcionite Church the fathers were equally energetic, Marcion and Valentinus during the period between 150 and 230 passing for the most dangerous heretics. Our oldest and at the same time fullest source is the work of Irenæus, which rests upon a tract of Ptolemæus and probably makes use of the *Syntagma*[4] of Justin. In all probability he had read nothing of Valentinus himself. Tertullian's *Adversus Valentinianos* is largely taken from Irenæus, but contains some things that are original and of very great value: he had either himself read some Valentinian works, or had at least obtained authentic information as to their contents. Our best sources for Valentinus himself are the *Stromata* and *Eclogues* of Clement of Alexandria, who had read much of Valentinus and something of Heracleon, and gives extracts from both. His *Excerpta ex Theodoto* are also invaluable. Hippolytus in both his works against heretics has transcribed Irenæus; yet in his *Philosophumena* he has followed a new source in describing the Valentinian system. Origen made a careful study of Heracleon's *Commentary on John's Gospel*, and in his own *Commentary* he frequently refers to it both approvingly and otherwise. The numerous fragments he has preserved have very great value for the historian. Lastly, Irenæus and Hippolytus have been transcribed by Epiphanius, who also has preserved various matters of importance, particularly the letter of Ptolemæus to Flora.

Valentinians.—The school of Valentinus soon divided into two main branches, that of Italy and that of Asia Minor.[5] Both in turn subdivided into various sections; but the Asiatic branch on the whole preserved most faithfully the teaching of the master. His influence spread even beyond the limits of the schools. Tatian, for example, in his later period indubitably derived much from Valentinus, and the fathers of the Alexandrian school were very largely indebted to him. Even in the time of Epiphanius Valentinians still existed in some districts of Egypt. The Italian branch had as heads of its schools Secundus, another master of uncertain name (Colarbasus? Epiphanius? see Iren., i. 11, 3), Ptolemæus, Heracleon, Theotimus, and Alexander. Secundus modified the master's doctrine of the æons and introduced a dualism into it. The anonymous scholar shows tokens of Pythagorean influence. But the most important, exceeding in the extent of their influence even the master himself, were Ptolemæus and Heracleon. The former made into hypostases the æons which Valentinus himself had regarded as impersonal powers of the one Godhead. He is the systematic and Biblical theologian *par excellence* of the Valentinian school, conspicuous for a powerful if also undisciplined phantasy; and in his letter to Flora he shows how thorough has been his study of the Old Testament, and how penetrating, how carefully considered, and how pointed his criticism of it. Heracleon, mentioned also by Irenæus, earned distinction by his *Commentary* (*ὑπομνήματα*) *on the Gospel according to John*, for it is probably the first scientific commentary that Christendom produced. Clement (*Strom.*, iv. 9, 73) calls him the most eminent teacher of the Valentinian school. He appears to have shown much greater sobriety than Ptolemæus, whose speculations recall those of the later Neoplatonists in a most striking manner, just as we find Valentinianism generally to have anticipated, not only the later scientific theology of the Catholic Church, but also Neoplatonism. Of Theotimus all that we know is Tertullian's remark (*Adv. Valent.*, 4): "multum circa imagines legis operatus est." Tertullian is also our sole informant about Alexander (*De Carne*, 17-20). He seems to have busied himself specially with the Christological problem, and to have written under the title of *Syllogismi* a treatise into which quotations from Valentinus's *Psalms* were introduced as authorities.

The names mentioned as those of leaders of the Asiatic school are Axionicus, Theodotus, and above all Bardesanes; we also have some fragments of Valentinian writings belonging to the East, but of which the origin is otherwise unknown.[6] Axionicus at Antioch[7] was the master's most faithful disciple. Clement of Alexandria has preserved excerpts of a very inconsecutive character and in a very corrupt text from a systematic work, and some commentaries of Theodotus (*Ἐκ τῶν Θεοδότου καὶ τῆς ἀνατολικῆς καλουμένης διδασκαλίας κατὰ τοὺς Οὐαλεντίνου χρόνους ἐπιτομαί*). These excerpts, which constitute one of the most important sources for Gnosticism generally, have not hitherto received the attention they deserve. Zahn (*Forschungen*, iii. p. 123 *sq.*) has tried to make out that Theodotus is identical with Theodas, Valentinus's master. But from the excerpts it seems hardly probable that they should be the work of a man who must have written at latest under the emperor Trajan. Bardesanes, though originally influenced by Valentinus, ultimately took up peculiar and independent ground of his own, and through him Valentinus exercised a great influence upon the Syrian Church, which continued until the 4th century (see SYRIAC LITERATURE, vol. xxii., p. 867). In Asia Minor the Valentinian collegia continued until past the middle of the 4th century (see *Epp. Juliani*). The church fathers bring into connection with Valentinus the Magian Marcus, as to whose doctrine we are very adequately informed by Irenæus, but it is questionable whether he can really be reckoned as one of the disciples of that master.

Teaching of Valentinus.—Valentinus made his appearance at a time when the Christian communities were still destitute of any fixed doctrinal system: they were still associations pledged to a holy life on the ground of their faith in the one spiritual God and in His Son Jesus Christ, closely held together by the bonds of brotherly love, and strictly separated from the world and from them that are without by the consciousness of having received the Holy Ghost. But an enormous volume of facts, of sayings, and of thoughts had by this time become current within the church, material drawn from the Old Testament, from the Gospel history, from the Pauline epistles, from other early Christian writings, and from the Hellenistic and apocalyptic literature of the Jews. How this material was to be arranged, how it was to be kept within bounds, and with what degree of authority it was to be invested were questions still unsettled. But one thing was certain—Paul had declared it, and every Christian apostle, prophet, and teacher had repeated it—that the Christian faith guaranteed knowledge supreme and complete, and led on from truth to truth. Another thing was sure—that all human wisdom was but folly in presence of this new "divine" wisdom, which was inclusive of all human knowledge. The means, moreover, by which every saying, every fact was to be turned into a profound thought had for long been known and in use in the Christian communities,—that of allegory. But as yet there was no settled principle fixing the manner in which the allegorical method was to be applied, or determining what were the ruling thoughts of Scripture. The attitude of Christian teachers towards the Jewish wisdom was as indeterminate as it was towards Greek philosophy. The Pauline theology was intelligible only to a very few, and the Old Testament was as it were a veritable sphinx. It was understood to be a superhuman book, but it was also understood that much of its contents, if taken literally, was valueless. In what sense was it to be understood? How much of it was to be taken literally and how much spiritually? Was everything to be taken spiritually? According to what principle was it on this assumption to be interpreted? Was the whole of it the revealed word of the Most High, or were various authors to be recognized? Might it possibly be that part of it was divine, part heroical, part genial, part natural, part false, and part devilish? Or was it perhaps true that no part of the book proceeded from the Most High God, that nothing was pneumatic, but all psychical or carnal? And, if the Old Testament was to be allegorized, must not the narratives and the sayings of the Gospels be also treated in the same way? Was not allegory here also the pathway to the thought? If the opening chapters of Genesis and the histories of the patriarchs and of the people of Israel were a profound philosophical poem, why should not also the life of Jesus Christ be only the veil of a cosmic mystery? All these questions had within the period from 60 to 130 exercised, not indeed the great mass of believers, for these were uneducated, but thinking Christians; and the more the Christian preaching enlarged its scope, the more Christians came into contact with Syrian, Samaritan, Egyptian, and Greek wisdom, and the more they found themselves called upon to make comparisons and to bring into clearness that which is peculiar to and distinctive of Christianity, it was inevitable that these questions should stir the minds of educated Christians all the more intensely. Upon the one basis of faith in Jesus Christ accordingly there were about the year 130 a great variety of groups, differing from one another in doctrine, worship, organization, and the like,[1] but differing also in their attitude to Christianity at large, some keeping themselves aloof from it because they regarded it as wholly perverted, others being driven out from it, others again, while remaining within the main body, yet forming special schools, or "mystery" unions, and so on. In Syria, as also in other portions of the Roman empire, the gospel was associated with Semitic "cultus wisdom" and with the abstruse speculations of a physical science still in its childhood; the entire Old Testament was rejected and an attitude of opposition assumed towards fellow-members in the great Christian union.

These developments, however, could reckon on only a relatively small degree of encouragement within the Græco-Roman world. The barbaric elements they contained were too conspicuous, and on the other hand they were too far removed from Jewish-Christian tradition and from Christian common sense. But the attractiveness must have been very great when, on the basis of Christian tradition and the mysterious traditions of Oriental peoples, a system was set up with the aids of Greek philosophical science for a school of "knowing ones" or "Gnostics," and a cultus organized for a community of the "initiated." This was what Basilides and Valentinus achieved. The importance of Valentinus lies in the facts, firstly, that he recognized the relationship (for such a relationship really existed) between the theogonic-cosmogonic myth-wisdom of western Asia and the Neopythagorean, Platonic, and Philonic philosophy; secondly, that he touched all this rich and varied material which he had appropriated with the magic wand of the Platonic conception of the universe, and thus transmuted the whole into entities of a purely spiritual character; and thirdly, that he gave a decisive part to the appearance of Jesus Christ in that great drama which the history of the higher and the lower cosmos presented to his mind. In all this he had no design of setting up a new "confession," and still less any notion (as Marcion had) of utterly remodelling Christianity. He was prevented from cherishing any such ideas by his conviction that men were divided by the inalterable constitution of their natures into three classes,—the "pneumatic," men of the spirit, genial natures, in whom sparks of the divinity are found; the "psychical," moral men, who can if they choose be ethically good; and "hylic" or carnal, hopelessly chained to that which is perceived by the senses. The ordinary members of Christendom at large he held to be "psychical," and esteemed them as such. But he did not regard their Christianity as *the* Christianity, rather only as its exoteric form. Alongside of the exoteric there had all along, according to him, existed an esoteric. The apostles did not say out everything to everybody, but on the contrary communicated to the "spiritual ones" a secret doctrine into which only select persons might be initiated, and that not until after long and careful probation. This secret teaching included a special dogmatic, a special ethic, and a special worship. But it was not out of all connection with the Christianity that was publicly taught. We can observe in the history of the Valentinian schools the zeal with which they strove to adapt themselves to the Christianity publicly professed, and to follow it in all its developments. The Valentinians always, so far as they possibly could, accepted such things as the development of the canon (agitated for by themselves) within the church at large, the building up of a tradition, the symbols framed, and the like; to this Irenæus, Tertullian, and the Alexandrians all bear witness. In this they present the strongest possible contrast to Marcion and his church, who from the outset took up an attitude of the utmost hostility to the main body of Christians. Hence they expressly even controverted Marcionitism, as the letter of Ptolemæus to Flora and the polemic of Bardesanes against the Marcionite Prepon show. If such was the unvarying attitude of Valentinus's scholars, it is fair to attribute it also to Valentinus himself. In his day indeed the dogmatic, ethical, and legal advances of Christendom at large were still in their most rudimentary stage, but what there was of them must have been valued by him even then as the exoteric form of Christianity, to which he superadded his own Gnostic esoteric form. In this respect he was the forerunner of Clement and Origen, who likewise distinguished Gnostic from common Christianity, and very probably learned the distinction from Valentinus and his scholars. But his connection with both was of a still more intimate character. They are related not only by virtue of the fact that they all regarded the gospel as the religion of the perfect Hellenically-cultured spiritual man, but also by the large-hearted disposition they cherished, and the settled purpose they manifested, to appropriate everything noble and great in the history of humanity, to rank it according to its proper value, and to find a place for it in the edifice of Christian philosophy. And it is very interesting to notice that they completely set aside the Greek and Roman mythologies, regarding them as worthless and devilish. The formal peculiarity of the Valentinian Gnosis is that it places all moral and intellectual ideas, possessions, and entities in a descending scheme of genetic development. With Valentinus himself they figure as "motus et affectus" of the Godhead, the ultimate cause of all things, the alone Good; by his scholars they are hypostatized. This descending development (self-revelation) of the Godhead takes place with a holy rhythm. At this point the Pythagorean speculations about numbers on the one hand and the ancient Semitic astrological wisdom on the other seemed important to Valentinus; but everything is made spiritual: even the old Semitic antithesis of "male" and "female" is adopted, but with an altered meaning.[2] The whole inner development of the primal cause (*βύθος*) into the pleroma, the cosmos of perfection, is designed to explain how it was that this world of appearance, of mixture, and of sin arose. Valentinus was a strict monotheist, but at the same time he discerned in the present world the mingling of irreconcilable elements. The problem then was how, while acknowledging the absolute perfection, goodness, and causality of God, to reconcile with this the existence of the actual pneumatico-psychico-hylic world, and at the same time to show the possibility of redemption in the case of those who are capable of it. Valentinus solved this problem by assuming that the self-unfolding of the Godhead is at the same time to be thought of as a dissipation of energy. God alone is *ἀγέννητος*. The powers emanating from Him (*νοῦς*, *ἀλέθεια*, *λόγος*, *ζωή*, *ἄνθρωπος* = ideal man, *ἐκκλησία*, and so on) are *γεννητά*. Hence, although *ὁμοούσια* with the Godhead, they have nevertheless a limitation attaching to them. They are copies of the Godhead in a descending line; but the copy is never of equal value with the pattern. The thirtieth and last æon, Sophia,[3] has the element of imperfection in the strongest degree. This belongs to it in the form of "passion" (πάθος), the passionate desire after full knowledge of and fusion with the primal God. This passion for the pleroma, having seduced the æon into overstepping its proper bounds, is accordingly separated from it and removed out of oneness with it; it thus falls into nothingness, the κένωμα, but gives the impulse to the making of this world. This world is the outward shaping of nothingness, of appearance, through connection with the fallen wisdom. It is a feeble copy of the pleroma without any abiding hold, but it includes pneumatic portions, though these have fallen very low. It was fashioned by the demiurge, an intermediate being brought forth by the fallen wisdom. The demiurge is psychical, and thus has no feeling and no understanding for the pneumatic which adhered to the elements of the world he framed. But over against the sensuous powers included in this world, so far as it is derived from nothingness, the demiurge is the representative of order, righteousness, freedom for better things, and the men who have received something of his spirit are those earnest moral natures who strive against their passions and aim at *justitia civilis*. Far above these stand the pneumatic ones, who, like their mother, have the strong passion of genius towards that which is highest, and in this possession, in knowledge and in the desire for knowledge, are raised far above the antithesis of the hylic (the devil) and the psychic (the demiurge). They carry within them an indestructible and divine element which is unintelligible to their very maker, but they are placed in a world which is foreign to them; they are as men imprisoned and fettered. Here it is that the Christian idea of redemption comes in. Jesus Christ appears. The declarations about Him in the Valentinian school were exceedingly various. We can find traces in them of all the contemporary and later Christologies of the Christian Church, even of the Adoptian. What they all had in common was (1) the idea that Jesus Christ made manifest was an exceedingly complex Being, in whom two or three natures, or even a greater number, had to be distinguished (compare Origen's Christology); (2) the conviction that the highest element in the Redeemer was not one of the æons which had somehow parted with some of its potential energy, but was the perfect self-manifestation of the Good, the Supreme God Himself; (3) the conception that the physical nature of Jesus Christ was no actual corporeity, but either something psychical or something pneumatical. This Jesus Christ then delivers all who are pneumatic in the world by communicating knowledge. By full knowledge of God, of the world, and of themselves they are raised above the world, enter upon their undying divine life, and finally are brought by Christ into the pleroma. But psychical persons also are redeemed by Him. They who hitherto have been brought up according to the laws of the Old Testament, that is, of the demiurge, now receive the perfect law; Jesus moreover by His death procured for them the forgiveness of sins. They are now therefore in a position to lead a perfect moral life, and after death, if they have made a right use of their freedom, shall be brought to an abode of bliss. The Valentinian ethic shows a fine combination of spiritual freedom with the element of asceticism. Their thesis, that primarily it is not the outward act but the intention that is important, was misunderstood by the fathers of the church as if they had given permission to pneumatic persons to live in license, to deny the faith under persecution, and the like. But there is no foundation for this. The fragments we possess from writings of Valentinus and his school show rather that they were second to no Christian body in moral earnestness. The Valentinians appear to have joined in the religious worship of the main body of the church so long as they were tolerated within it. But along with this they celebrated their own mysteries, in which only the initiated might take part.

---

[1] See Harnack, *Dogmengesch.*, i. p. 171 *sq.*

[2] The earliest opponents of the Valentinians distinguished them sharply from the "Gnostics." They rightly perceived that the Semitic and mythological element was for the Valentinians merely the material, which they filled with the spirit of Hellenism. Some of the heads of schools, however, dealt with this material in a highly fantastic fashion, and accordingly the church fathers say with justice that "inolescentes doctrinæ Valentinianorum in silvas jam exoleverunt Gnosticorum" (Tert., *Adv. Valent.*, 39).

[3] The number 30 comes from astronomy: at bottom the æons of Valentinus are 29½, the number of days in the lunar month.

In the foregoing sketch only the broad general outlines of the Valentinian theology have been indicated. In all the schools, and even with Valentinus himself, it was much richer and more complicated than has been indicated. But all was strictly wrought out, and even the apparently abstruse served always for the expression of a weighty thought. Very manifold and various were in particular the doctrines about the fallen wisdom (Sophia) and about its relations to the world and the demiurge; very various also were the views of Jesus and of Christ and of their relation to the pleroma of the æons. Finally their representations about "Horos" differed widely. "As a harlot daily changes her attire," says Tertullian in his malicious way, "so do the Valentinians change their opinions." But none of these differences affected the oneness of the general view. That the history of redemption constitutes along with the history of nature and of the world one grand drama, that it is for scientific cosmology to explain how it is that the "mixtures" have come to pass, and that it is for scientific sotierology to show how the "separations" have been brought about, as to these matters all were at one. Equally were they at one in their view of Christ as the absolute revelation of God, and in the persuasion that the creator of the world is identical with the God of the Old Testament, and is an "intermediate" Being. But the various Valentinian schools were above all united in their attitude towards the Scriptures. They were Biblical theologians: that is to say, they started from the conviction that complete wisdom lay only in the words of Jesus Christ, or, in other words, in the Gospels. They accordingly sought to base their systems throughout on the words of the Lord, applying to these the allegorical method. In a secondary degree they availed themselves also of the writings of the apostles. Their dogmatic claimed—as afterwards did that of Origen—to be evangelical and apostolic; but, since they interpreted the New Testament after the same method as that which Philo applied to the Old, it was as a rule Platonic thought that they introduced into the plain and simple words of Jesus, and thus the fathers of the church were not without justification in calling them "sectatores Platonis" (Tert., *De Præscr.*, 30). As their method of exegesis supplied them with the means of everywhere finding the sense that suited them, it is highly improbable that they were at the trouble to prepare any new scriptures. The fathers do not as a rule charge them with either fabrication or falsification, but only with perversion of the Word through wrong interpretations. Nor did they dispute or reject the Roman creed; they simply, by a peculiar interpretation, put their own meaning upon it; yet at the same time they had alongside of it their own "regula fidei." It is hardly probable that they possessed an "evangelium veritatis" of their own, but it is not impossible. They subjected the Old Testament to an admirable religious criticism. Ptolemæus distinguished in the law (1) what the demiurge had said; (2) what came from Moses; (3) what the later teachers of the law had added. Amongst those portions which were regarded as having proceeded from the demiurge himself, he again distinguished three groups: (*a*) the Decalogue, which is of perpetual obligation, and which only required to be completed by Christ (in the sermon on the mount); (*b*) those commands which were given only for a season on account of the shortcomings of the people, and which were abolished by Christ; (*c*) the ceremonial law, which had a typical meaning that was fulfilled by Christ. They denied that anything in the Old Testament came from the supreme God, the God of goodness and love.

From the fragments of Valentinus and of Heracleon and Theodotus the student can learn how these Valentinians anticipated the ecclesiastical speculations of subsequent centuries. The following points may be mentioned in this connection: (1) the speculation as to ὁμοούσιος, ὅμοιος, ἑτερούσιος, ἀγέννητος, and γεννητός, by which they prepared the way for the Unitarian problem in its scientific shape: (2) their speculation about "Jesus" and "Christ" and about His various natures, by which they opened the way for later Christology; (3) their scientific allegorical treatment of the New Testament Scriptures and their undertaking to found their whole system upon the sacred writings of Christianity, thus anticipating Origen's dogmatic; (4) their distinction of the perficienda, abroganda, and implenda in the Old Testament, which paved the way for the doctrine of Irenæus and Tertullian in reference to the law; (5) their doctrine of baptism; (6) their doctrine of the Lord's Supper; (7) their doctrine of purification after death, in which they anticipated the later dogma of purgatory (Origen, Augustine, Gregory I.); (8) their twofold ethic (for psychical and for pneumatic persons; see Clement and Origen, as also the monachism of the Catholic Church); (9) and finally the view destined later to play so large a part within the church, that the soul of the Christian Gnostic is the bride of Christ.

Literature.—The fragments have been collected by Grabe (*Spicilegium*, ii. 430 *sq.*) and Hilgenfeld (*Ztschr. f. wiss. Theol.*, 1880, p. 280; 1881, p. 214; 1883, p. 356). The system is set forth more or less in the works on Gnosticism by Neander, Matter, Baur, Lipsius, Hilgenfeld, Mansel, and Möller. See also Heinrici, *Die Valent. Gnosis. u. d. heil. Schrift* (1871), and Rossel, *Ges. Schriften* (1847). (A. HA.)

VALENTINUS, pope for thirty or forty days in 827, in succession to Eugenius II. (824–827), was a Roman by birth, and according to the *Liber Pontificalis*, was first made a deacon by Paschal I. (817–824). Nothing further is known of his history. His successor was Gregory IV. (827–844).

VALERIAN, a genus of herbaceous perennial plants of the natural order *Valerianaceæ*. Two species—*Valeriana officinalis*, L. (see vol. iv. pl. VIII.), and *V. dioica*, L.,—are indigenous in England, while a third, *V. pyrenaica*, L., is naturalized in some parts of Scotland and the west of England. The valerians have opposite leaves and small flowers, usually of a white or reddish tint, and arranged in terminal cymes. The limb of the calyx is remarkable for being at first inrolled and afterwards expanding in the form of pappus. The genus comprises about 150 species. In medicine the root of *V. officinalis* is intended when valerian is mentioned. The plant grows throughout Europe from Spain to the Crimea, and from Iceland through northern Europe and Asia to the coasts of Manchuria. Several varieties of the plant are known, those growing in hilly situations being considered the most valuable for medicinal purposes. Valerian is cultivated in England (in several villages near Chesterfield in Derbyshire), but to a much greater extent in Prussian Saxony (in the neighborhood of Cölleda, north of Weimar), in Holland, and in the United States (Vermont, New Hampshire, and New York).[1]

The dried root or rhizome consists of a short central erect portion, about the thickness of the little finger, surrounded by numerous rootlets about $\frac{1}{10}$ of an inch in diameter, the whole being of a dull brown color. When first taken from the ground it has no distinctive smell; but on drying it acquires a powerful odor of valerianic acid. This odor, now regarded as intolerable, was in the 16th century considered to be fragrant, the root being placed among clothes as a perfume (Turner, *Herbal*, part iii., 1568, p. 76), just as *V. celtica* and some Himalayan species of the genus are still used in the East (see Spikenard). By the poorer classes in the north of England it was esteemed of such medicinal value that "no broth, pottage, or physical meat" was considered of any value without it (Gerard, *Herball*, 1636, p. 1078).

Valerian owes its medicinal properties to a volatile oil, which is contained in the dried root to the extent of one or, more rarely, two per cent., plants growing on dry or stony soil yielding the largest quantity. The oil is a complex body, consisting of a terpene, $C_{10}H_{16}$; an alcohol, $C_{10}H_{18}O$, isomeric with borneol, and compounds of the alcohol with formic, acetic, and valerianic acids; and an ether having the formula $C_{10}H_{17}O$. The valerianic acid occurring in the oil is not the normal acid, but iso-valerianic acid. The other constituents of the root are malic acid, resin, sugar, etc. Valerian is employed in medicine as a stimulant and antispasmodic in various forms of hysteria, and in chorea and hooping cough; it is also stated to possess anthelmintic properties.[2] The red valerian of cottage gardens is *Centranthus ruber*, also belonging to the *Valerianaceæ*; but Greek valerian is *Polemonium cœruleum*, belonging to the natural order *Polemoniaceæ*. Cats are nearly as fond of the smell of this plant as of the true valerian, and will frequently roll on the plant and injure it.

VALERIANUS, Publius Licinius, Roman emperor from 253 to 260, was a man of ancient family and is first mentioned in the year 238 as *princeps senatus*. Some thirteen years later, when Decius restored the censorship and added to the office legislative and executive powers so extensive that it embraced the best part of the civil authority of the emperor, Valerian was chosen censor by the senate, to whom the appointment was committed. The death of Decius cut short this novel experiment in government, but Valerian retained the confidence of Gallus, who sent him to fetch troops to quell the rebellion of Æmilianus. The soldiers in Rhætia, however, proclaimed Valerian emperor; and marching slowly towards Rome he found both his rivals dead. Valerian was already an elderly man—he is said to have been seventy years old at his death—and had scarcely the vigor to confront with success the enemies that threatened every frontier of the empire, but he applied himself to his heavy task with diligence and goodwill. Taking his son Gallienus as colleague, and leaving the wars in Europe to his direction, under which matters went from bad to worse and the whole West fell into disorder, Valerian chose for his own part the war in the East, where Antioch had fallen into the hands of a Persian vassal and Armenia was occupied by Shápúr, while in 258 the Goths ravaged Asia Minor. Valerian recovered Antioch, fought in Mesopotamia with mixed success, and finally was taken captive (see Persia, vol. xviii., p. 619). His ultimate fate is unknown.

VALERIUS, Publius, surnamed Publicola, the colleague of Brutus in the consulship in the first year of the Roman republic. According to the legend represented by Livy and Plutarch (see Rome), he was a member of one of the noblest Roman families, being son of Volusus, a descendant of a Sabine of that name who had settled in Rome along with King Tatius. He was one of those who witnessed the death of Lucretia, and joined in the oath to avenge her wrongs. He took a prominent part in the expulsion of the Tarquins, and though not originally chosen as the colleague of Brutus he soon afterwards took the place of Tarquinius Collatinus. On the death of Brutus, which left him alone in the consulship, the people began to fear that he was aiming at kingly power. To calm their apprehensions, he discontinued the building of a house which he had begun on the top of the Velian Hill, overlooking the Forum, and also gave orders that the fasces should henceforward be lowered whenever he appeared before the people. He introduced various laws further to protect the liberties of the citizens, one of these enacting that whosoever should attempt to make himself a king might be slain by any man at any time, and another providing an appeal to the people on behalf of any citizen condemned by a magistrate. For these services the surname of Publicola or Poplicola was conferred on himself and on his descendants forever. He was thrice re-elected to the consulship, and during his fourth term of office he received the honor of a triumph for his victory over the Sabines. He died in the following year (503 B.C.), and was buried at the public expense, the matrons mourning him for ten months.

VALERIUS FLACCUS. See Flaccus.

VALERIUS MAXIMUS, Latin writer, author of a collection of historical anecdotes, published his work in the reign of Tiberius. Prefixed to many MSS. of the collection is a life of the author, but it is a late and worthless compilation, and the only trustworthy information concerning his career is drawn from a few passing allusions in the book itself. The family of Valerius was poor and undistinguished; for the great Valerii Maximi who are conspicuous in the annals of the early Roman republic cannot be traced lower than the Punic Wars. Valerius himself professes to have owed everything to Sextus Pompeius, who was descended from a paternal uncle of the great Pompey. This Pompeius was a kind of minor Mæcenas, and the centre of a literary circle to which Ovid belonged; he was also the intimate of the most literary prince of the imperial family, Germanicus. He took Valerius with him when he went to Asia as proconsul. Although Valerius does not state that his profession was that of a teacher of rhetoric, the fact is betrayed by every page of his writings. In his prooemium he plainly intimates that he is putting forth a kind of commonplace book of historical anecdotes for use in the schools of rhetoric, where the pupils were severely trained in the art of embellishing speeches by references to history. The title for the work in the MSS. is "Books of Memorable Deeds and Utterances." No ancient reader would have expected accuracy in such a book, and the indignation expressed by many modern scholars at its glaring historical errors has been much misplaced. The stories are very loosely and irregularly arranged in nine books, each book being divided into sections, and each section bearing as its title the topic, most commonly some virtue or vice, or some merit or demerit, which the stories in the section are intended to illustrate. Most of the tales are from Roman history, but each section has an appendix consisting of extracts from the annals of other peoples, principally the Greeks. The exposition exhibits strongly the two currents of feeling which are intermingled by almost every Roman writer of the empire,—the feeling that the Romans of the writer's own day are degenerate creatures when confronted with their own republican predecessors, and the feeling that, however degenerate, the latter-day Romans still tower above the other peoples of the world, and in particular may take much comfort to themselves from their moral superiority to the Greeks.

---

[1] [*V. officinalis* is common in gardens in the U. S., and is sometimes called "garden heliotrope" from the odor of its flowers.—Am. Ed.]

[2] [Valerianate of zinc has been largely used as a remedy for neuralgia.—Am. Ed.]

The range of authorities from whom the collection is drawn is undoubtedly narrow. It has even been maintained that Valerius used four authors only,—Cicero, Livy, Sallust, and Pompeius Trogus; there are, however, clear traces of others, as of Varro, Asinius Pollio, and Herodotus. By far the largest part of the matesial comes from Cicero and Livy, though each is only mentioned once by name. Valerius was neither a well-read nor an able man. His treatment of his material was careless and unintelligent in the extreme; but for all that he did not miss his aim. Even though in one tale Tanaquil be made the wife of Ancus Martius, and in another Æschylus be mistaken for Pericles, though the Scipios and the Catos be mingled in confusion, though conflicting versions of the same occurrence be given, and the most startling anachronisms presented, yet the excerpts are none the less apt illustrations, from the rhetorician's point of view, of the circumstance or quality they were meant to illustrate. Scholars have long since ceased to corrupt the text of Valerius, as Pighius did, to save his character for historical accuracy, nor do they now, with Perizonius, distort his meaning for the pleasure of adding to the list of his sins. What, then, are his claims to the attention of modern students? In the first place, the existing literary remains of the time in which he wrote are extremely scanty, and mere scarcity confers value on many articles which are in themselves poor. And even on the historical side we owe something to Valerius. He often used sources now lost to us, and where he touches on his own time he affords us some glimpses of the much debated and very imperfectly recorded reign of Tiberius. His attitude towards the imperial household has often been misunderstood, and he has been represented as a mean flatterer of the same type with Martial. But, if the references to the imperial administration be carefully scanned, they will be seen to be extravagant neither in kind nor in number. Few will now grudge to Tiberius, when his whole action as a ruler is taken into account, such a title as "salutaris princeps," which seemed to a former generation a specimen of shameless adulation. The few allusions to Cæsar's murderers and to Augustus hardly pass beyond the conventional style of the writer's day. The only passage which can fairly be called fulsome is a rhetorical pæan over the death of Sejanus. But it is as a chapter in the history of the Latin language that the work of Valerius chiefly deserves study. Without it our view of the transition of classical into silver Latin would be much more imperfect than it is. Erasmus declared that Valerius is no more like Cicero than a mule is like a man, which is only another way of saying that he had in excess the faults of his age. The entire life, thought, and literature of the first century and a half of the empire were steeped in the influences of rhetoric, enthroned in the seat of education. In Valerius are presented to us, in a rude and palpable form, all the rhetorical tendencies of the age, unsobered by the sanity of Quintilian and unrefined by the taste and subtlety of Tacitus. Here we have the loathing for direct and simple statement and the pursuit of novelty at any price. Every device which can put a gloss of newness on the language is eagerly adopted. The barrier between the diction of poetry and that of prose is broken down; the uses of words are strained; monstrous metaphors are invented; there are startling contrasts, dark innuendoes, and highly colored epithets; the most unnatural variations are played upon the artificial scale of grammatical and rhetorical figures of speech. It is a most instructive lesson in the history of Latin to set side by side and compare minutely with each other a passage of Valerius and its counterpart in Cicero or Livy.

In the MSS. of Valerius a tenth book is given, which consists of the so-called "liber de prænominibus," the work of some grammarian of a much later date. The collection of Valerius was much used for school purposes, and its popularity in the Middle Ages is attested by the large number of MSS. in which it has been preserved. Like other school books it was epitomated. One complete epitome, probably of the 4th or 5th century, bearing the name of Julius Paris, has come down to us; also a portion of another by Januarius Nepotianus. The best edition of Valerius with explanatory matter is that by C. Kempf (Berlin, 1854); the best text is that by C. Halm (Leipsic, 1865).

VALETTA, or **VALLETTA**. See MALTA, vol. xv. pp. 343–6. The population was 24,854 in 1881, and was estimated at 26,700 in 1888.

VALLA, **LORENZO** (*c.* 1406–1457), one of the most salient personalities of the earlier Italian Renaissance, was born at Rome, of parents derived from Piacenza, possibly in the year 1406–07, or perhaps somewhat earlier.[1] He was educated in the humanistic schools of Rome, according to the customs of that age, learning grammar from some humble dominie and afterwards attending the classes of eminent professors. Valla mentions Leonardo of Arezzo as his chief master in Latin and Giovanni Aurispa in Greek. He wished to establish himself as apostolic secretary in the Eternal City. But for some reason or other this office was refused him. At the age of twenty-four he went to Piacenza on family affairs, and from this city proceeded to Pavia, where he obtained a professorship of eloquence. Like all the scholars of that time, Valla wandered from university to university, accepting short engagements and airing his talents as a lecturer in many cities. It appears that he professed the New Learning in Milan and Genoa as well as Pavia. Somewhere, and at some uncertain date during this period, he came into relations with Alphonso of Aragon, who conquered the kingdom of Naples. Valla did not, however, follow this prince's fortunes in the early days of their acquaintance. We find him once more in Rome in 1443 during the pontificate of Eugenius IV. At this period of his career Valla won the highest reputation by his dialogue *De Voluptate* and his treatise on the *Elegances of the Latin Language*. In the former work he contrasted the principles of the Stoics with the tenets of Epicurus, openly proclaiming his sympathy with those who claimed the right of free indulgence for man's natural and sensuous appetites. It was a remarkable utterance, since the paganism of the Renaissance here found, for the first time, deliberate expression in a work of scholarly and philosophical value. The *Elegantiæ* was no less original, though in a different sphere of thought. This work subjected the forms of Latin grammar, the rules of Latin style and rhetoric, to critical investigation. It placed the practice of composition upon a foundation of analysis and inductive reasoning. But there was a third essay composed by Valla during the pontificate of Eugenius which displayed the same originality and a like critical acumen. This bore the title of a *Treatise on the Donation of Constantine*; and in it Valla proved that the claims founded by the Roman see upon that supposed grant reposed on forged documents and legendary fables. It was not published until 1440, when Valla had been already three years resident at Alphonso's court in Naples.

There was every reason why the king of Naples should be interested in a man of Valla's stamp. He wished to attract scholars of the highest ability to his capital, and he was always on bad terms with the papacy. Valla combined the qualities of an elegant humanist, an acute critic, a freethinker, and a venomous pamphleteer who had committed himself to a destructive polemic against the temporalities of Rome. Accordingly the king made him his private secretary, encouraged him to open a school of rhetoric in Naples, and defended him against the attacks of friars and inquisitors. From Naples Valla continued his war of pamphlets against the church. He proved that the letter of Christ to Abgarus was a forgery, ridiculed the Latinity of the Vulgate, questioned the authenticity of the Apostles' Creed, and accused St. Augustine of heresy. If is a singular note of that period in Italy that, on the death of Eugenius IV., his successor, Nicholas V., invited Valla to Rome, not to arraign him before the bar of the Inquisition, not to punish him for his insolent criticism, but in order to confer upon him the post of apostlic secretary, with substantial pecuniary appointments. This entrance of Valla into the Roman curia has been justly called "the triumph of humanism over orthodoxy and tradition." Nicholas had no other object than that of fixing one of the chief scholars of the age near his own person. He allowed Valla to open a school of eloquence in Rome, and he paid him munificently for translating Thucydides into Latin. Thus, for the sake of his erudition and stylistic talents, the supreme pontiff rewarded a man whose chief titles to fame are the stringent criticism with which he assailed the temporalities of the church, and the frank candor with which he defended a pagan theory of human conduct.

---

[1] [Drackenborch in vol. vii. of his edition of Livy has given a full account of Valla, placing his birth in 1407, but others say five years later.—AM. ED.]

All the biographical notices of Valla are loaded with long accounts of his literary quarrels. Intolerant of rivalry, inordinately vain, and greedily self-seeking as the scholars of that epoch were, they indulged in the fiercest internecine warfare among themselves. The bulky folios of their works contain hundreds of invectives which may be ranked among the most obscene, the most wearisome, and the most disgraceful products of the human intellect. Valla won a regrettable celebrity by the number and the virulence of his enmities. Bartolomeo Fazio, Georgios Trapezuntios, and Poggio felt the stabbing sharpness of his pen. It must, however, be admitted that these antagonists gave back quite as good as they got. It is almost impossible to form a just estimate of Valla's private life and character through the dust-clouds of abuse and dirt which these controversies stirred up around his memory. He died at Naples in the year 1457. Posterity honors in him not so much the stylist and the scholar as the initiator of a bold critical method, applied to language, historical documents, and ethical opinions.

The collected edition of Valla's *Works* is that of Basel, 1465. For detailed accounts of his life and work, consult Tiraboschi; Voigt's *Wiederbelebung des Alterthums;* and Symonds's *Renaissance in Italy* (vols. ii. and v.).

VALLADOLID, a province of Spain, one of the eight into which Old Castile is now divided, is bounded on the N. by Leon and Palencia, on the E. by Burgos, on the S. by Segovia, Avila, and Salamanca, and on the W. by Zamora. The area is 3043 square miles and the population in 1877 was 247,458. The province belongs entirely to the basin of the Douro, which traverses it from east to west, and within its limits receives the Pisuerga (with the Esgueva) on the right, and the Duraton, Adaja (with the Eresma), and Zapardiel on the left. The country watered by these rivers is for the most part flat and exceedingly fertile, the only part that can be called in any sense hilly being in the northwest, where the low Montes de Torozos occur. For the excellence and abundance of its grain crops Valladolid shares with La Mancha the title of granary of the peninsula. Besides the ordinary cereals and pulses, the province produces hemp, flax, various fruits, red and white wine, oil and madder. The Montes de Torozos are well clad with oak and other timber. The pastures are extensive and large numbers of horses, mules, and sheep, as well as some cattle, are reared, while honey, wax, and silk are also produced. The woollen fabrics of Valladolid were once highly esteemed, but this industry has now greatly declined. Some trade is carried on, facilitated by the Canal of Castile, which connects Valladolid, on the Pisuerga, with Alar del Rey, in Palencia, also on that river. The province is traversed by the national highways from Madrid to Santander, Leon, and Coruña, and the Calatayud and Salamanca roads may also be regarded as trunk lines. It is also traversed from north to south by the northern railway, which has a branch from Valladolid to Rioseco. There are 11 partidos judiciales and 237 ayuntamientos. The most important places besides Valladolid, the capital (see below), are Medina de Rioseco (4776 inhabitants in 1877) and Medina del Campo (5296).

VALLADOLID, capital of the above province, on the left bank of the Pisuerga, at its confluence with the Esgueva, which traverses the town by two channels, is situated (about 2250 feet above sea level) 150 miles by rail to the northwest of Madrid. The site is in a small valley enclosed by steep and broken, though not very high, ground. The town, which was formerly surrounded by walls and entered by four principal gates, contains some fine streets and squares, especially the so-called Plaza Mayor, but on the whole it has a dull and deserted aspect, though of late years its industrial and commercial activity has somewhat revived. The granite cathedral, begun in 1585, would, if carried out according to the original design of Herrera, be a magnificent specimen of the Græco-Roman style of that architect; only the nave, however, was ever completed, and the tower (one of four in the plan) fell in 1841. The interior is well proportioned, but bare. The tower and nave of the church of Sta. Maria la Antigua date from about 1200. The church of San Pablo is later (1286); its chief feature of interest is a beautiful flamboyant portal, and formerly it had exquisite cloisters. Adjoining is San Gregorio (15th century) with a fine Plateresque façade. San Benito, dating from the end of the 14th century, is an elegant Gothic building with a lofty roof finely groined. The college of Santa Cruz, a classical building founded in 1479, now houses a collection of pictures and sculptures of little value, except for some examples of Rubens and of the work of Berruguete. The university was founded in 1346; but the present Rococo building dates from the decadence of architecture in Spain. Among other public buildings of Valladolid may be mentioned the royal palace, built in the beginning of the 17th century, and the court-house and town-hall; several ex-convents are now used as barracks. Along the banks of the rivers are several public walks adorned with trees and fountains. The principal industries are the manufacture of linen, silk, and woollen fabrics, pottery, gold and silver work, leather, and paper. There is a considerable trade in the abundant agricultural produce of the vicinity. The population in 1877 was 52,206.

Valladolid is usually identified with the ancient Pintia of Ptolemy, described in the *Itinerary* as a town of the Vaccæi on the road from Asturica to Cæsaraugusta. The present name is usually, but rather obscurely, explained as equivalent to Beled Walid, "the land of Walid." The town was recovered from the Moors in the 10th century, but is first named in a public document by Sancho II. of Leon in 1072. The cortes of Castile frequently met here in the following centuries, and in the beginning of the 15th century John II. made it his principal residence. After the removal of the capital to Madrid by Philip II. in 1560 it began rapidly to decay. In December, 1808, it was taken and sacked by the French, and in the January following Bonaparte resided here for some days, and caused the destruction of many fine buildings and works of art. Columbus died (1506) and Philip II. was born (1527) at Valladolid.

VALLADOLID, a city of the state of Michoacan de Ocampo, in Mexico. See MORELIA.

VALLADOLID, a town in the state of Yucatan, Mexico, lying towards the centre of the northern plateau, on the river Bolina, about 90 miles southeast of Merida, with which it is about to be connected by a railway. Valladolid, which with the suburban district has a population (1885) of 18,470, mostly Indians and half-castes, is situated in the healthiest and best cultivated part of Yucatan, and is accordingly much frequented by invalids. The town is well built, with regular streets, and low but substantial houses, generally fronted by a garden plot and shady trees. Amongst its buildings are seven fine churches, a large Jesuit college, a town-hall, a hospital, and a well-constructed aqueduct. But like everything else in Yucatan the place presents a general appearance of decay, although there is a considerable local cotton industry. Some miles to the east lie the remarkable ruins of Chichen-Itza, covering a space of nearly two miles in circumference. Amongst these remains are several sonatos, or tanks, from 65 to 200 feet in diameter and 50 to 110 feet deep, with steep rocky sides, in which water is still stored.

Valladolid is one of the oldest Spanish settlements in Yucatan, having been originally founded by Francesco de Montejo at a place called Chauachaa in 1543. But it was removed the next year to Zaqui, about 15 miles from the sea, with easy access to the port of El Cuyo, and soon after to its present position.

VALLE, Pietro della (1586–1652), to whom we owe one of the best books of Eastern travel, came of a noble Roman family which had produced two cardinals, and was born, on 11th April, 1586, in the family palace built by Cardinal Andrea. His early life was divided between the pursuits of literature and arms. He saw active service against the Moors of Barbary, but also became a member of the Roman Academy of the *Umoristi*, and acquired some reputation as a versifier and rhetorician. To the latter quality we owe some tedious passages in his *Travels;* but that book gives also sufficient evidence of solid and useful learning in the classical authors, which served him well, particularly in the first part of his wanderings. The idea of travelling in the East was suggested by a disappointment in love, as an alternative to suicide, and was ripened to a fixed purpose by a visit to the learned Mario Schipano, professor of medicine in Naples, to whom the record of Pietro's travels was addressed in the form of very elaborate letters, based on a full diary. Before leaving Naples he took a vow of pilgrimage to the Holy Land, and sailing from Venice on 8th June, 1614, reached Constantinople, where he remained for more than a year, and acquired a good knowledge of Turkish and a little Arabic. On 25th September, 1615, he sailed for Alexandria with a suite of nine persons, for he travelled always as a nobleman of distinction, and with every advantage due to his rank. From Alexandria he went on to Cairo, and, after an excursion to Mount Sinai, left Cairo for the Holy Land on 8th March, 1616, in time to assist at the Easter celebrations at Jerusalem. Having sedulously visited the holy sites, he journeyed by Damascus to Aleppo, and thence to Baghdad, where he married a Syrian Christian named Maani, a native of Mardin. He now desired to visit Persia; but, as that country was then at war with Turkey, he had to leave Baghdad by stealth (4th January, 1617). Accompanied by his wife, who was the courageous and constant companion of his Persian journeys until her death in consequence of a miscarriage (30th December, 1621), he proceeded by Hamadan to Ispahan, and joined Shah Abbas in a campaign in northern Persia, in the summer of 1618. Here he was well received at court and treated as the shah's guest. On his return to Ispahan he was occupied with political schemes hostile to the Turk, the alliance of Persia with the Cossacks and the king of Poland, and also with a project for the foundation of a Catholic colony in Persia; at the same time he diligently continued his Oriental studies and observations. He now began to think of returning by India rather than adventure himself again in Turkey; but the state of his health, and the war between Persia and the Portuguese at Ormuz, created difficulties. In October, 1621, he started from Ispahan, and, visiting Persepolis and Shiraz, made his way to the coast; but, after long delay and many troubles—his wife dying at Mina—he was forced to return to Shiraz, after the capture of Ormuz, and it was not till January, 1623, that he found passage for Surat on the English ship "Whale." In India he remained till November, 1624, his headquarters being Surat and Goa. He was at Muscat in January, 1625, and at Bussorah in March. In May he started by the desert route for Aleppo, and, after a short stay there and a visit to Antioch, took ship at Alexandretta on a French vessel. Touching at Cyprus and doing quarantine at Malta, he reached Rome on 28th March, 1626, and he was received with much honor, not only by literary circles, but by Pope Urban VIII., who appointed him a gentleman of his bedchamber. The rest of his life was uneventful; he married as second wife a Georgian orphan of noble family, Mariuccia (Tinatin de Ziba), whom his first wife had adopted as a child, and who had accompanied him in all his journeys. By her he had fourteen sons. He died at Rome on 21st April, 1652.

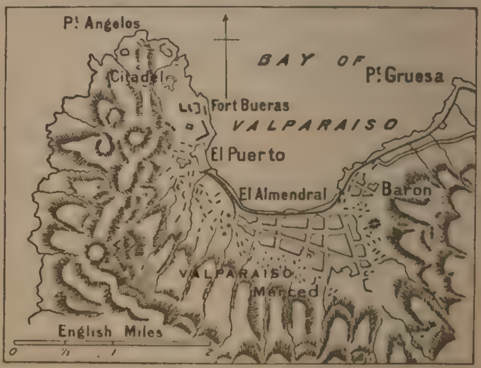
In Pietro della Valle's lifetime there were printed (1) a *Funeral Oration on his Wife Maani*, whose remains he brought with him to Rome and buried there (1627); (2) an *Account of Shah Abbas*, printed at Venice in 1628, but not published; (3) the first part of the letters describing his *Travels* (Turkey, 1650). The *Travels* in Persia (2 parts) were published by his sons in 1658, and the third part (India) in 1663. An English translation appeared in 1665 (fol.). Of the Italian text the edition of Brighton, 1843 (2 vols. 8vo), is more esteemed than the other reprints. It contains a sketch of the author's life by Gio. P. Bellori (1622). Della Valle's story is often prolix, with a tendency to the rhetorical. He has no turn for incident, an absolute want of humor, and little real literary faculty of any kind; but he is clear and exact, well informed, and very instructive, so that his work still possesses high value.

VALLEJO, a city of Solano county, California, United States, is situated on the shore of San Pablo Bay, near the western end of the Straits of Carquinez. It has an excellent harbor, and railroad communication by a branch of the Central Pacific Railroad. The city contains large flour-mills; the population in 1880 was 5987. Vallejo, which takes its name from the Mexican general M. G. Vallejo, who took the country from the Indians in 1835, was in 1854 the capital of the State of California.

VALLOMBROSA, Order of. See Monachism, vol. xvi. p. 734–5.

VALLS, a town of Spain, in the province of Tarragona, 11 miles to the north of that town, on a height near the Francoli. It is an old town and its walls and towers still remain. The usual Catalonian industries of wool and cotton spinning and weaving, as well as dyeing, distilling, paper-making, and tanning are carried on with considerable activity. The population within the municipal boundaries in 1877 was 13,250.

VALPARAISO, a city of Chili, the chief town of the province of the same name, and one of the principal commercial ports on the west coast of South America, is situated on a fine bay of the South Pacific Ocean, in 33° 0′ 2″ S. lat. and 71° 41′ 15″ W. long., 70 miles northwest of Santiago, with which there is communication by a circuitous railway of 115 miles. The city lies at the south part of the bay, which is 2½ miles wide, semicircular in form, and well sheltered, except towards the north. There is good anchorage in the roadstead. There are two floating docks, capable of accommodating vessels of from 1400 to 3000 tons. The city is situated at the base of a range of barren hills, varying from 1000 to 1400 feet in height, which have a narrow strip of low land betwen them and the sea; on this and on sites formed by cutting away the



Plan of Valparaiso.

cliffs most of the houses are built. Further space is afforded by the deep dells or watercourses between the hills. These open towards the sea, and are on both sides covered with houses. Much of the foreshore has been raised by earthquakes. The erection of an extensive embankment was begun in 1885. The older portion (Puerto) of the city, in which are the principal public and commercial buildings, is separated from the newer portion, called the Almendral, by a projecting point. The city is defended by a chain of forts, begun in 1866. The principal public buildings are the Government palace, the custom house, the large bonded Government warehouses, the hospital, the city hall, and two theatres. The educational institutions include a theological seminary, a naval academy, and a lyceum; the last-named had 415 students in 1884 and 481 in 1885. The commercial enterprise of the city is largely dependent on the foreign merchants, especially Englishmen, Americans, and Germans. It is the commercial capital of Chili, and the principal residence of the foreign consuls. The principal industrial establishments are the Government railway shops, a large foundry and machine shops, coach-building and wheel-wright works, and a very large sugar refinery, the raw material for which is obtained from Peru. The population (97,737 in 1875) was 95,000 in 1885, of whom about a tenth were foreigners.

The number of vessels in the foreign trade that entered the port in 1885 was 587 of 582,066 tons, the number that cleared 348 of 373,551 tons. More than half of the tonnage was British,—Chilian, German, and French following in the order named. In the coasting trade the number of vessels that entered in 1885 was 781 of 434,486 tons, the number that cleared 1050 of 640,138 tons. About nine-tenths of the tonnage was British and Chilian, the latter having a slight advantage. The following table shows the value of the import and export trade during five years, 1881 to 1885:

Year.	Imports.			Exports.			Total.		
	£	s.	d.	£	s.	d.	£	s.	d.
1881	7,437,545	8	2	7,891,783	0	0	15,329,328	8	2
1882	8,563,650	17	4	10,713,669	6	8	19,277,320	4	0
1883	9,673,618	13	6	11,441,571	7	4	21,115,190	0	10
1884	9,414,841	1	0	9,441,757	1	8	18,856,598	2	8
1885	6,620,326	18	2	8,324,446	17	8	14,944,773	15	10

The foreign trade is chiefly with Great Britain, France, Germany, and the United States, the value of the exports to these countries in 1885 being £1,356,583 [$6,493,993.38], £110,312 [$536,816.50], £262,065 [$1,273,635.90], and £15,424 respectively, and of the imports £1,787,310 [$8,686,326.60], £911,080 [$4,427,848.80], £900,066 [$4,427,848.80], and £318,629 [$1,548,536.94] respectively. The principal exports are metals (nitrate, bar copper, silver produce, copper and silver regulus, and gold and silver specie), wheat, barley, flour, wool, nuts, hay, beans, honey, iodine, coal, hides, and guano; and the imports include iron, steel, wire, nails, machines and tools, sugar, rice, cashmeres, prints, shawls, wines and beer.

Valparaiso was founded in 1536[1] by the Spanish officer Juan de Saavedra, who named it after his birthplace near Cuenca in Spain. In 1578 the city was captured by Drake, the exact date of his appearance before it being 5th December; and it was again taken by Hawkins's expedition in 1596. In 1600 it was sacked by the Dutch corsair, Van Noort. It was visited by severe earthquakes in 1730 and 1822, and by earthquake shocks in 1839 and 1873. It suffered from fire in November, 1858; and on 31st March, 1866, it was bombarded by the Spanish fleet under Admiral Nuñez, when a large part of the town was laid in ruins.

VALS, or Vals-lès-Bains, a village of France, in the department of Ardèche, with a population of 2186 in 1886, is noted chiefly for its alkaline waters, which are similar to those of Vichy (see vol. xvi., p. 452). Within the commune, which in 1886 had a population of 3911, paper is manufactured to a small extent, and some silk is spun.

VALTELLINA, or Valtelline, the upper valley of the Adda, in the extreme north of Italy (province of Sondrio), derives its name from Teglio, the former capital, not far from Tirano (Val di Teglio, Val Teglina; Germ., Veltlin), and has a length, from Bormio to the Lake of Como, of about 68 miles. The chief town is Sondrio (4014 inhabitants in 1881), other important places being Tirano (3119) and Morbegno (3240). Near Bormio (Germ., Worms) there are some frequented mineral springs (sulphur and lime), known in Pliny's time, and efficacious in diseases of the skin. There are several other baths in the side valleys, such as Santa Caterina (chalybeate), Masino, and Le Prese (sulphur). The highest points in the ranges enclosing the valley are the Piz Zupo (13,121 feet) in the Bernina group and the Königsspitze (12,645 feet) in the Ortler district; the Monte della Disgrazia (12,074 feet) is the highest peak comprised entirely within the water-basin of the valley. Three well-marked Alpine passes are traversed by good carriage-roads—the Stelvio Pass or Stilfserjoch (9046 feet, the highest carriage-road in Europe) from Bormio to Meran in the Adige valley, the Bernina Pass (7628 feet) from Tirano to Samaden in the Upper Engadine, and the Aprica Pass (4049 feet) from Tirano to the Val Camonica and the Lake of Iseo. The main valley is traversed from end to end by a magnificent carriage-road constructed by the Austrian Government in 1820–25. A railway from Colico, on the Lake of Como, to Sondrio (27 miles) was opened in 1884, and is being pushed on towards Tirano. The population is wholly Italian-speaking and Roman Catholic, the valley being in the diocese of Como. The shrine of the Madonna of Tirano (founded 1520) annually attracts a large number of pilgrims. The valley, particularly in its lower portion, is extremely fertile; and of late years vigorous measures have been taken to prevent the damage caused by the frequent inundations of the Adda. Chestnuts, vines, mulberry trees, and fig trees abound; and there are many picturesquely-situated churches, castles, and villages. The chief articles exported are wine and honey. The wine is largely consumed in north Italy and Switzerland, the best varieties being Grumello, Sassella, and Montagna. About 20,000 ℔ weight of honey is annually sent abroad. Politically the whole valley belongs to the kingdom of Italy, except the side valley of Poschiavo (Puschlav), which belongs to the Swiss canton of the Grisons (Graubünden).

The political history of Valtellina is made up of the histories of three districts—(1) the "free community" of Poschiavo (first mentioned as such in 1200–01); (2) the county of Bormio (first mentioned as a county in 1347); and (3) Valtellina proper, extending from the defile of the Serra di Morignone on the east to the Lake of Como on the west. After the defeat of the Lombards (774) these three districts were given by Charlemagne to the abbey of St. Dennis near Paris, which never seems to have exercised its rights. In 824 Lothair I., confirming an earlier donation made by Charlemagne, gave the churches of Poschiavo and Bormio to the Bishop of Como. Bormio was in 1205 won by the men of Como, who in 1006 had received one-half of Valtellina from the emperor, and by 1114 they were masters of the entire valley. They retained Bormio till 1300, when it freed itself; but in 1336 it belonged to the bishop of Chur. In 1335 the Visconti, lords (later dukes) of Milan, became lords of Como, and therefore of Valtellina. In 1350 they seized on Bormio and Poschiavo, the latter being won back by the bishop of Chur in 1394, and again lost to the Visconti in 1435. As early as 1360 the men of Rhætia made incursions into Valtellina under the pretext that it had formed part of ancient Rhætia. This idea was confirmed in 1404, when, in return for kind treatment received during his exile, Mastino Visconti (son of Barnabo) gave to the bishop of Chur his share of the Milanese, including Poschiavo, Bormio, and Valtellina. Relying on this donation, the men of the Three Leagues of Rhætia (best known by the name of one, Graubünden) invaded the valley in 1486–87, Poschiavo becoming in 1486 permanently a member (not a subject land) of the *Gotteshausbund*. This donation served too as the excuse for seizing, in 1512, on Bormio and Valtellina, which were harshly ruled as "subject bailiwicks." Under the governor at Sondrio there were four "podestas" for the three divisions of Valtellina (Morbegno and Traona, Sondrio, and Tirano), besides one at Teglio and one at Bormio. Mastino Visconti's donation was solemnly confirmed in 1516 by the emperor Maximilian I. In 1530 the bishop of Chur was forced to sell to the Three Leagues for a small sum his title to these two districts. At the time of the Reformation Poschiavo became Protestant. The other two districts clung to the old faith and came under the influence of Carlo Borromeo, who, when founding in 1579 his "Collegium Helveticum" at Milan for Swiss students for the priesthood, reserved for Valtellina six out of the forty-two places. Valtellina was extremely important to the Hapsburgs as affording the direct route between their possessions of the Milanese and Tyrol. Hence a great struggle, into which religious questions and bribery largely entered, took place between Austria and Spain on one side, and France and Venice on the other. In 1603 Fuentes, the Spanish governor of the Milanese, built a fortress (of which traces still remain) close to the Lake of Como and at the entrance to the valley, in order to overawe it. The religious conflicts in Graubünden led to reprisals in the "subject land" of Valtellina. In 1620 (19th July–4th August) the Spanish and Romanist faction (headed by the Planta family) massacred a great number of Protestants in the valley, 350 to 600 according to different accounts (*Veltliner Mord*). For the next twenty years the valley was the scene of great strife, being held by the Spaniards (1620, 1621–23, 1629–31, 1637–39), by the French (1624–26, 1635–37), and by the pope (1623, 1627). At length George Jenatsch, a former pastor, who had been the active and unscrupulous leader of the Protestant party, became a Romanist (1635) in order to free the land from the French by aid of the Spaniards (1637), who finally (1639) gave it back to its old masters on condition that the Protestants were excluded from the valley. In this way the local struggles of Valtellina came to be mixed up with the Thirty Years' War. In 1797 Bormio and Valtellina were annexed to the Cisalpine republic, in 1805 to the kingdom of Italy (of which Napoleon was king), and in 1815 (despite the remonstrances of the Rhætian leagues) to the kingdom of Lombardo-Venetia, held by the emperor of Austria. In 1859 they became, like the rest of Lombardy, part of the kingdom of united Italy. Poschiavo followed the fortunes of the "Gotteshausbund." It became (after 1798) part of the canton Rhætia of the Helvetic republic, and in 1803 of the canton of the Graubünden or Grisons, which was then first received a full member of the Swiss Confederation.

VALUE. In most departments of economic theory it is convenient to use as the basis of the exposition the opinions of J. S. Mill, not only because he has embodied in his treatise in a remarkable manner nearly everything of importance from the theoretical standpoint in the work of his predecessors, but also because most of the recent advances in economic science have been made by way of criticism or development of his views. This observation is especially true of the theory of value. In this subject Mill had digested the mass of previous learning with such effect that he commences his treatment with the remark: "Happily there is nothing in the laws of value which remains for the present or any future writer to clear up; the theory of the subject is complete. The only difficulty to be overcome is that of so stating it as to solve by anticipation the chief perplexities which occur in applying it." Curiously enough this part of economic theory was the first to receive at the hands of Jevons and others serious modification, the nature and need for which can, however, only be properly understood after a preliminary examination of the old orthodox position.

Value in use and in exchange.

Price.

As regards the question of definition, Mill starts with the distinction somewhat loosely drawn by Adam Smith between value in use and value in exchange. When we say that a thing possesses a certain value in use, we say in more words than are necessary that it is useful; that is to say, value in use is an awkward phrase for utility. The conception of utility (see Wealth) is the most fundamental in economics. It is held by Mill to mean the capacity to satisfy a desire or serve a purpose, and thus "useful," the corresponding adjective, is as fitly applied to ices as to steam-engines. But utility is obviously much wider than value, and Mill proceeds to say that by value in political economy we should always understand exchange value. This language seems familiar and definite, but on analysis it is clear that exchange implies two terms at least. If we say that a thing can be exchanged, we imply that it can be exchanged for something else, and when we speak of the exchange value of a thing we must directly or indirectly refer to the value of some other thing or things. In practice in modern societies this other thing is standard money: an Englishman who talks of the exchange value of anything means the number of pounds sterling (or parts thereof) which it will fetch in the market or be appraised at by a fair arbitrator. On this view then the value of a thing is its price; but a very little experience in the theory or history of economics will show that it is often desirable, and sometimes necessary, to contrast value with price. "At the same time and place," says Adam Smith, "money is the exact measure of the real exchangeable value of all commodities. It is so, however, at the same time and place only." If, however, the exchange value of a thing is not its price, what is it? According to Mill, "The value of a thing is its general power of purchasing, the command which its possession gives over purchasable commodities in general." But what, we may well ask with Mill, is meant by command over commodities in general? Are we to understand the complete national inventory of wealth, or the total of things consumed in a given time by a nation? Obviously such conceptions are extremely vague and possibly unworkable. If, however, we make a selection on any representative principle, this selection will be more or less arbitrary. Mill is to some extent aware of these difficulties, although he never subjected them to a rigorous analysis; and he points to the obvious fact that a coat, for example, may exchange for less bread this year than last, but for more glass or iron, and so on through the whole range of commodities it may obtain more of some and less of others. But in this case are we to say that the value of the coat has risen or fallen? On what principles are we to strike an average? The attempt to answer these questions in a satisfactory manner is at present engaging the attention of economists more than any other problem in the pure theory. Mill, however, instead of attempting to solve the problem, frankly assumed that it is impossible to say except in one simple case. If, owing to some improvement in manufacture, the coat exchanges for less of all other things, we should certainly say that its value had fallen. This line of argument leads to the position: "The idea of general exchange value originates in the fact that there really are causes which tend to alter the value of a thing in exchange for things generally, that is, for all things that are not themselves acted upon by causes of similar tendency." There can be no doubt as to the truth of the latter part of this statement, especially if we substitute for one commodity groups of commodities. But it is doubtful if the idea of general exchange value arises from a consideration of the causes of value; and recent writers have constantly emphasized the distinction between any change and the causes of the change. Following out the idea in the last sentence quoted, Mill goes on to say that any change in the value of one thing compared with things in general may be due either to causes affecting the one thing or the large group of all other things, and that in order to investigate the former it is convenient to assume that all commodities but the one in question remain invariable in their relative values. On this assumption any one of them may be taken as representing all the rest, and thus the money value of the thing will represent its general purchasing power. That is to say, if for the sake of simplicity we assume that the prices of all other things remain constant, but that one thing falls or rises in price, the fall or rise in price in this thing will indicate the extent of the change in its value compared with things in general. There can be no doubt that, in discussing any practical problem as to the changes in the relative value of any particular thing, it is desirable to take the changes in price as the basis, and much confusion and cumbrousness of expression would have been avoided in the theory of the subject if, to adapt a phrase of Cournot's, money had by Mill and others been used to oil the wheels of thought, just as in practice it is used to oil the wheels of trade.

Requisites for value.

By this method of abstraction the treatment of the theory of value becomes essentially an examination of the causes which determine the value of particular commodities relatively to a standard which is assumed to be fixed. Now in order that anything may possess value in this sense, that it may exchange for any portion of standard money or its representatives, it is evident on the first analysis that two conditions must be satisfied. First, the thing must have some utility; and secondly, there must be some difficulty in its attainment. As regards utility, Mill apparently regards it simply as a kind of entrance examination which every commodity must pass to enter the list of valuables, whilst the place in the list is determined by variations in the degree of the difficulty of attainment. Later writers, however (more particularly Jevons), have given much more prominence to utility, and have drawn a careful distinction between final and total utility. This distinction is useful in throwing light on the advantages of, and motives for, exchanging commodities. Suppose that on a desert island A possesses all the food, so many measures—(say) pecks—of corn, and B all the drinking water, so many measures—(say) pints. Then A, taking into account present and future needs, might ascribe to the possession of each portion of his stock so much utility. The utility of the first few pecks of corn might be regarded as practically infinite; but, if his stock were abundant, and a speedy rescue probable, the utility ascribed to successive portions would be less and less. In the same way B might make an estimate of the utility of successive measures of the drinking water. Now, if we regard only *total* utilities from the point of view of each, both are infinite. If an exchange were made of the total stocks of both men, the position of neither would be improved. But, if A sets aside (say) half his stock, then it may well happen that he could advantageously exchange the rest against part of B's drinking water. In precisely the same way B might set aside so much of his stock for his own consumption, and then the utility of the remaining portion would be much less than the utility he would gain if he obtained in exchange A's surplus. Thus, if the two men exchange their remainders, both will gain in utility; in the case supposed they will make an enormous gain. For simplicity we have supposed each stock to be divided into two portions, but nothing has been said of the principles of the division. It is, however, clear that A can advantageously go on exchanging a measure of corn for a measure of water so long as by doing so he makes a gain of utility. Conversely B can advantageously offer water so long as he gains greater utility from the corn received in exchange. The utility of the last portion of corn retained by A (or of water by B) is the *final* utility of the stock retained, and similarly the utility of the last measure obtained in exchange may be called the final utility of the stock purchased. A will have done his best if these utilities are just equal. For at this point, if he were to offer (at the same rate of exchange) more corn, it is clear that he would lose more utility than he would gain. *Mutatis mutandis*, the same reasoning applies to B; and thus the rate of exchange will be so adjusted as to bring about this equality of final utilities on both sides.[1] It follows that, if A gains on the last portion received just as much utility as he loses on the portion parted with, on all the other portions received he will have gained more than he lost. The total of these gains over successive portions has been called by Prof. Marshall *consumer's rent*.

Final and total utility.

Difficulty of attainment.

However useful this theory of final utility may be in throwing light on the fundamental nature of value, and on the advantages of exchange, it is obviously too abstract to be applied to the explanation of the relative values of the endless series of commodities and services which constitute a nation's stock of valuables at any time. For this purpose we must resort to the law of supply and demand, which requires a very careful statement owing to the ambiguities of popular language. Mill has succeeded in getting rid of most of these ambiguities, but he has hardly given due emphasis to the fundamental character of the law. He argues, after the brief consideration allotted to the element of utility, that the other preliminary condition necessary for value—difficulty of attainment—is not always the same kind of difficulty, and he arrives at three distinct laws of value, according to the forms or degrees of this difficulty. (1) In the first place the difficulty may consist in an absolute limitation of the supply, and in this case the corresponding law is said to be the law of supply and demand. Even on Mill's view the class of commodities which comes under this heading is both large and important, for it includes not only the favorite examples of old pictures, china, etc., but also land, and especially building sites in large cities. Again, it is pointed out that, although comparatively few commodities may be absolutely limited, almost all commodities may be so locally and temporarily, which is really only another way of saying that the law of supply and demand governs all market values; for it is obvious that the supply actually forthcoming or obtainable in a specified time in any market is limited,—a point which may be well illustrated by the extreme case of a "corner." Again, under certain circumstances the supply may be artificially limited, as in the case of monopolies, a typical example being the destruction by the Dutch of some of their spice, in order that the limited quantity might sell for a total higher price. Besides all these important instances of the operation of the law of supply and demand, Mill is compelled also to bring under the same law the wages of labor, the values of the staples of international trade, and some other peculiar cases of value. In fact, step by step, he is almost forced to the conclusion, now generally accepted, that the law of supply and demand is the fundamental law of value, of which the other laws are only particular cases. At the outset, however, he appears to consider the two others as of co-ordinate importance. (2) When the difficulty of attainment consists not in the absolute limitation but simply in the fact that the article requires labor and capital to produce it, the normal or natural value is said to be determined by the cost of production. (3) In the last case taken by Mill it is supposed that an article can be increased in quantity, but only at an increasing cost, and in this case the corresponding law of value is the cost of production of that portion which is obtained under the most unfavorable circumstances. These three laws of value may now be examined critically and their mutual relations discussed, for the last two, if not properly of co-ordinate importance with the first, are at any rate wide generalizations.

Three laws of value.

In order to understand the law of supply and demand, it is best to take separately the general law

---

[1] For a full account of the theory of which only the principles are here indicated, see Jevons, *Theory of Pol. Econ.*, London, 1871.

Law of supply and demand.

Law of demand.

of demand and the general law of supply, and then effect a combination. Demand must be defined as the quantity of any article demanded at some particular price, it being assumed, of course, that the bidder of the price can meet his engagements, or, as is sometimes said, that the demand is an effectual demand. It is quite clear that by demand we cannot simply mean desire to possess, because in a sense every one desires everything, and the less the means of payment so much greater in general is the desire. Again, it is obviously necessary to insert the qualifying clause "at some particular price," because, as a rule, with a change in price a different quantity will be demanded. It is, indeed, this variation of quantity demanded, according to variation in price, which gives rise to the statement of the general law of demand, namely: As the price of any article falls, other things remaining the same, the quantity demanded increases, and, conversely, as the price rises the quantity demanded decreases. A very good example of this law is found in the effects of the remission of taxes. The repeal of a tax leads to a fall in price and the fall in price is accompanied by increased consumption. Conversely, it has often been found that to increase the amount of a tax does not increase the revenue from it, because the demand for the article falls off. The precise connection between the price and the quantity demanded differs in different cases, and, strictly speaking, is probably never the same for any two commodities. At the same time, however, commodities may be placed in large classes according to the general character of the variation. The variation of quantity demanded according to price will ultimately rest on the principle of *final utility* explained above. A person with a limited amount of money to spend will hit the economic mark in the centre if the final utilities of his several purchases are equal. This is a rather technical way of saying that a prudent man will not spend a penny more on any particular thing if the penny spent upon some new object would give him a little greater satisfaction. Reverting to the variations of demand according to price, a contrast will at once be observed between necessaries and luxuries. However much the price rises, so long as people have the means they must consume a certain amount of necessaries, but, however much the price falls, the limit of consumption of bread, for example, must soon be reached. On the other hand, a great fall in price of many luxuries may cause an enormous increase in the demand whilst a great rise may almost destroy the demand. A great deal of light might be thrown on many interesting problems in the progress of a nation and of its various component classes, if the laws of demand, or the statistics of consumption according to price, were obtainable.

Law of supply.

Turning to the element of supply, this term in a similar way may be defined as the quantity offered for sale at some particular price, and the general law of supply may be stated thus: As the price rises, other things remaining the same, the quantity offered tends to increase, and, conversely, as the price falls the quantity offered tends to diminish. Expressed in this manner, supply appears to be exactly analogous to demand, and the analogy seems to hold good even when we push the analysis up to the utility to the seller as compared with the utility to its buyer. For, as the price rises, the seller will obtain greater utility, and will thus retain less for his own use or will be induced to produce more. On closer inspection, however, the law of supply is found to be not so simple as the law of demand. It would only be so if the seller had simply to compare the relative advantages of exchanging his commodity and of retaining it for his own use, without any further reference to the conditions of, or the motives for, production. In most commodities, however, the determining influence is not the comparative utility of consumption by the owner on the one hand or of the consumption of something else obtained by exchange on the other, but it is rather a comparison of the trouble of producing with the advantage of selling the article when produced. Of course, if we are considering finished products in any market the case is more simple; but even here the question of the relative advantages of present sale and reservation for a future market or distant place must be determined, and then the element of cost of production will again be brought back.

Equation between demand and supply.

Before considering the relation of cost of production to supply, it will be convenient to combine the laws of supply and demand, taking the former in its simplest aspect, and to state the general law of supply and demand as governing value. Excluding the simple case of the barter of two commodities on which the rate of exchange will be determined as explained above in reference to final utility, and meaning by demand the quantity demanded in a market at a certain price, and by supply the quantity there and then offered at a certain price, the general law may be stated thus: In any market the price of any article will be so adjusted that the quantity demanded will exactly equal the quantity offered at that price. The force by which the adjustment is made is, in general, competition. Thus, if the price were above the point indicated by the law, there would be a lessened demand and the competition of sellers would tend to lower the price. Conversely, if the price were lower the competition caused by the increased demand would tend to raise it. The law as thus stated corresponds to what Mill calls the equation between demand and supply. He was induced to adopt this phrase in place of the more popular expression, the ratio of demand to supply, on the ground of its greater accuracy. And, if the term ratio is to be taken strictly, no doubt Mill's criticism is perfectly just. At the same time the equation must be stated very carefully to avoid falling into the truism suggested by Cairnes, namely, that in any market the quantity bought at any price is equal to the quantity sold at that price. The point is that in accordance with the general principles of supply and demand the quantities offered and demanded vary with the price. And, however inaccurate the literal use of the term ratio may be, it has the advantage of suggesting a change of price according to changes in demand and supply.

Monopoly values.

It may be useful at this point to consider the principles by which monopoly values are regulated. The simplest case is when one individual possesses the whole stock and the cost of production is so small that it may be neglected. Take the case, for example, of some natural well having a unique character for the mineral waters it supplies. The monopolist will, in the first place, have to discover the law of demand for his article. If he fixes a very high price, he may only occasionally sell a pint to a king or a millionaire, whilst, if he fixes a very low price, he may sell to every peasant and yet get a very poor return. He will, in fact, have to work out a problem in mathematics, and must so adjust his price that the quantity sold multiplied by the price per unit will be a maximum. The same kind of difficulty is found in the case in which the expenses of production, although considerable, are practically fixed or only increase slightly in proportion to the quantity furnished. The minimum price will be given by the expenses of production, whilst the actual price will tend to be such as to yield the maximum profit. Take, for example, the case of a steamer which has a practical monopoly and is not controlled by Government. The owner will not send out the steamer at all unless the passengers and cargo pay the expenses; but, if there is a great demand, he will raise the price so as to secure a maximum profit. In general, however, any

Competition values.

increase in the quantity of the article produced (or the service rendered) will be accompanied by an increase in the necessary outlays, and this increase may be greater or less per unit. In these cases the calculation of the maximum profit is a matter of great difficulty. Take, for example, the case of a railway which has a monopoly in a certain tract of country. The manager may aim at keeping down expenses and charging high rates, being contented with a moderate traffic; or he may lower his charges and incur additional expense to increase the gross income. It is worthy of remark that in many cases the monopolist has a choice of two methods which give practically equally good results, one starting with low and the other with high prices. But it is clear that the mass of the general public or the great body of consumers have an interest in low prices being adopted, whilst, on the other hand, the tendency is usually for the monopolist to charge higher prices than are really profitable in a maximum degree. The simplicity of the method of high prices is always attractive and often deceptive. Accordingly, even on these very general grounds, the interference of Government with monopolies may be defended as being in the interests of the public and not against the interests of the monopolists. The case of the parliamentary third-class tickets furnishes an instructive example. At first the railways made their parliamentary trains as slow and inconvenient as possible, whereas now there is hardly a train which does not carry passengers at parliamentary rates without compulsion. In a similar way many cases of Governmental interference with landowners may be justified, for very often there is a tacit combination on the part of a few great landowners to act on certain customs.[1] As a rule, however, in modern commercial countries monopolies are an exception. Any one, for example, can prosecute any trade or manufacture if he can provide the requisite skill, labor, and capital, and even as regards land,—at any rate in the greater part of England and Scotland,—there is from the point of view of cultivation no real monopoly. But, when competition arises, exceptional profit ceases, and thus a new principle for determining values comes into play. If the producer of any article is obtaining more than the usual rate of profit, he at once provokes competition, and thus even the dread of this possible competition may keep down prices. This is often expressed by saying that the potential supply affects prices almost as much as the actual supply. It thus becomes obvious that, as regards freely produced commodities the production of which may be extended indefinitely at the same or at a decreasing cost, the value tends to conform to the minimum cost of production, and that any other value is consequently unstable. It will be observed, however, that cost of production only determines values by operating through the actual or potential supply, and thus that the law of demand and supply is fundamental. Once a thing is made, the actual cost of production has no influence on its value, except as indicating the conditions of future possible supply.

Cost of production.

At this point it becomes necessary to analyze and explain the nature of cost of production. In the last resort it will be found that nothing can be produced without labor, and in a modern society capital must be added. Thus the component elements of production are labor and capital acting by natural forces upon raw material. But, since both the forces and the produce of nature require labor and capital for their exploitation, the elements that must be considered primary and fundamental in the case of commodities that can be indefinitely increased are labor and capital. Capital again, is itself a product of labor, and it is also wealth set aside by the owner for future use instead of for present consumption. Accordingly, in order that a thing may be continuously produced, labor must obtain a sufficient reward for toil and capital a sufficient reward for "abstinence," or for preservation and accumulation of wealth. Thus the ultimate elements in the real cost of production are the toil and trouble and irksomeness of labor and of saving. But this toil and trouble will not be submitted to unless in any particular case the fair reward of industrial competition is forthcoming. However much pleasure a good workman may take in his work or a prudent man in his savings, in the industrial world as at present constituted both labor and capital will be attracted towards the point of highest reward (compare Wages); and, accordingly, it is a necessary condition of the production of any article that the price obtained will yield the average rate of wages and profit obtainable for that species of work. Now these rates of wages and profit can be expressed in terms of money, and may be designated, following Prof. Marshall, the *expenses of production* as distinguished from the *real cost*. The real cost of production would on analysis consist of a confused unworkable mass of "efforts and abstinences," and the relation of these mental strains to their material rewards is the problem of wages and profits. But for the purpose of relative values it is not necessary to push the analysis so far, and thus, if we regard the capitalist as the producer, we may look on the elements of production as consisting of wages and profits. And this is quite in accordance with customary thought and language: every one who asks for the details of the cost of a thing expects to have a statement of the wages and profits directly involved, and of the material, which again directly involves wages and profits. So far, then, as freely produced commodities are concerned, the general law is that they tend to sell at such a price as will yield on the average the ordinary rate of wages and profits which by industrial competition the occupation can command. It is at this point that the difficulty emerges as to the precise nature of the connection between the prices of commodities and the money wages and profits of producers. Are we to consider that the former are determined by the latter, or the latter by the former? If, for example, commodity A sells for twice as much as commodity B, are we to say that this is because wages are higher in the former case, or are the wages higher because the price is higher? The answer to this question is given in the theory of Wages (*q. v.*). It is sufficient to state here that, in discussing relative values, we may assume that industrial competition has established certain relative rates of wages and profits in various employments, and that any prices of articles which yielded more than these rates, whilst in other cases no corresponding rise took place, would be unstable. Thus, in discussing the normal values of freely produced commodities we have to consider the quantity of labor and the rates of wages, and the quantity of capital and the rate of profits, the *normal* rates of these wages and profits being given.

Expenses of production.

Wages and values.

Normal value.

The use of the term "normal" requires some explanation. The word *norma* properly refers to the square used by masons and carpenters, etc., and thus a thing may be said to be in its normal position, when no change will be made: that is to say, the normal position is the stable position, or it is the position to which the workman will try to adjust his work. And, similiarly, by the use of normal as applied to wages and profits, we mean the stable rate or the rate towards which they are attracted. It is thus quite possible that the normal rate may differ from the average rate or the rate obtained over a term of years. For it may easily happen that as regards wages, for example, a high rate for a short period may lead to such an increase in that kind of production that for a much longer period the rate will fall below the normal. The normal rate seems to refer to the actual conditions of industry, the rate which can be obtained for a given amount of exertion, taking the average of employments at the time, rather than to the particular rate obtained for some class of work over a period of years.

---

[1] The general theory of monopolies is admirably treated by the French mathematician and economist Cournot, *Revue Sommaire des Doctrinis Economiques*, Paris, 1877.

With these explanations the proposition holds good that the normal values of freely produced commodities tend to be equal to their cost, or rather expenses, of production, and any price which yields a greater or less return to labor and capital is unstable.

Elements of expenses of production.

If all commodities were produced directly by the expenditure of labor, and in such a way that capital need not be considered, as in the simple natural state of society taken by Ricardo, then the only element to consider in value would be the quantity of labor. And in a society of a more developed character, in which wages are paid, if we consider that the rate of wages is uniform, and that profits may be disregarded in comparison with wages, the quantity of labor is the most important consideration, and fall in the relative value of any article can only take place through some economy of labor. But, as we approach more nearly to the actual constitution of modern industrial societies, we find serious differences in the rates of wages in different employments, the use of fixed capital becomes of greater importance, and in some cases the lapse of time necessary for the completion of the commodity is considerable. Thus interest and profits, as well as the differential rates of wages, have to be taken into account just as much as the quantity of labor, and it is generally convenient to consider also the established differences in various returns to capital under different conditions (risk, irregularity, etc.). Indirectly, of course, since all capital in the ordinary sense is the result of labor, the quantity of labor is always of primary importance; but in considering the proximate causes of relative values, it is best to consider capital and labor as independent factors. It follows, then, that, in order to compare the relative values of two commodities, A and B, freely produced in a modern industrial society, we must take into account, first of all, the relative wages and relative profits, and the relative amounts of labor and capital employed. If the producers of A are skilled workmen, and if the return to the capital is uncertain, whilst in the case of B the labor is unskilled and profit steady, then the value of A will be higher than that of B, supposing each produced by the same amount of capital and the same quantity of labor. Obviously, too, any change in the relative wages and profits will affect the relative values. If the commodities considered are not capable of division into similar parts (such as yards of cloth or silk), but must be considered in their entirety (*e.g.*, ships and houses), then we must take into account also the different quantities of labor and capital required for their completion, as well as the relative rates of wages and profits. As regards changes of value in this case, it will be observed that, if the proportions are different in which labor and capital are employed in the production of two commodities, then any change in the *general* rates of wages and profits will affect relative values. By making various suppositions as to changes in the different elements of the expenses of production, a great many cases may be obtained, as is done, for example, by Mill (*Pol. Econ.*, bk. iii. ch. iv.). All the cases enumerated and others may, however, be deduced from a general formula. Let E_1 represent the total expenses of production of commodity A. Let Q_1 be the quantity of fixed capital employed, and let r_1 be the rate of wear and tear per annum, so that the loss is Q_1/r_1. Let P_1 be the rate of profits per cent. per annum which must be obtained on the whole capital. Let Q_2 be the number of laborers, and w_2 the rate of wages per annum. Let t_1 represent the time taken for production reckoned in years (t_1 may be less than unity, thus t_1/Q_2 would be weeks). Then the total expenses of production are

General formula for expenses of production.

$$E_1 = \left\{ Q_1\left(\frac{P_1}{100} + \frac{1}{r}\right) + Q_2 . w_2\left(1 + \frac{P_1}{100}\right) \right\} t_1.$$

This simply means that the commodity must return in the normal case profits on the fixed capital with repair of waste, and also the wages expended (the amount depending on the number of laborers and the rate of wages), with profit on the circulating capital over all the time necessary to complete production. In some cases, it may be observed, it would be necessary to take t differently for the fixed capital and the labor or circulating capital. Then, in a similar way, E_2, the expenses of production of B, may be expressed:

$$E_2 = \left\{ Q_3\left(\frac{P_3}{100} + \frac{1}{r_3}\right) + Q_4 . w_4\left(1 + \frac{P_3}{100}\right) \right\} t_2.$$

Changes in relative values.

Thus the relative values of A and B will be found by comparing the aggregate of these several elements expressed on the right hand sides of the equations. It will now be evident on what a number of variable elements relative values must depend, even when we consider that the commodities can be indefinitely increased by the proper expenditure of capital and employment of labor. With the progress of invention and the development of industrial competition, constant changes are taking place in the various elements, and in the somewhat complicated formula given certain practical elements have been eliminated. Even if we suppose, for the sake of simplicity, that P_1 and P_3 are equal, as also w_2 and w_4 and t_1 and t_2,—that is, if we suppose a uniform rate of wages and profits, and the same amount of time required,—still any change in these *general* rates will affect relative values, owing to the different proportions in which fixed and circulating capital may be employed in the two cases. Thus, for example, we arrive at Mill's statement: "All commodities in the production of which machinery bears a large part, especially if the machinery is very durable, are lowered in their relative value when profits fall." And it will be found on trial that by making various suppositions as to the identity of certain of the elements, or as to their disappearance, many other causes of changes in relative values may be deduced. Two important practical conclusions of a general character may be drawn from this analysis. (1) Relative values are liable to constant disturbances, and accordingly, since relative prices tend to be adjusted to relative values, relative prices must be constantly changing. (2) It is extremely difficult to measure changes in the value of the monetary standard, or movements in the general level of prices, or variations in the purchasing power of money incomes.

Value and rent.

These difficulties are further increased by the importance of the group of commodities which can only be increased (the arts of production remaining the same) at an increasing cost, and which are placed by Mill under a third law of value. The most important examples of this law are agricultural and mining produce. In order to make the principles on which this law depends clear and intelligible, it is necessary to proceed at first by the abstract method so well described by Cairnes (*Logical Method of Pol. Econ.*, 2d ed., London, 1885). Assume then that there is an isolated country and that its agricultural produce consists of corn. Then at any given stage of the growth of wealth and population the amount of corn may be increased (the art of agriculture remaining stationary) either by taking into cultivation inferior lands or else by cultivating with greater care and expense the lands already in cultivation. But in either case what is known as the law of diminishing return would come into play, and the additional supply could only be obtained at an additional cost. It may be assumed that at any stage of development the cultivation would be carried to such a point as to give just the ordinary return to capital on the last "dose" of capital expended. Further it cannot be carried, for no farmer will work at a continuous loss; and competition will insure that it is carried so far, for, if this last application of capital yields ordinary profit, the former "doses" must yield more, that is to say, rent as well as profit. It thus becomes manifest that, under the conditions supposed, the extent to which "the margin of cultivation" will extend depends upon the price of the produce, and in the normal case —The price must be equal to the expenses of production of that part which is produced under the most unfavorable circumstances. This, then, is the third law of value, from which the economic theory of rent is an immediate deduction. For, if the last dose obtains just a sufficient return, the former doses must yield more, and the sum of these extra profits is rent. It thus appears, also, that rent depends upon price and not price upon rent.[1]

Qualifications of pure theory of rent.

The pure theory of rent is arrived at by making certain hypotheses and abstractions, and accordingly it must not be applied to particular practical cases without further consideration. The theory certainly indicates the effect of very important causes, but requires in practice a certain amount of qualification. (1) The essence of the theory is that the return to each dose of capital applied can be separated, and that the application of capital will cease when the last dose yields only ordinary profits; and no doubt it is roughly true to say that a farmer will discover on trial at what point he should cease applying capital, and that this will depend upon the price of the produce. At the same time, however, it is quite possible that a farmer who owns the land which he tills may find it advantageous to carry cultivation to a further pitch than if he only rented his land. For he will apply his own labor and capital at a less return on his own land. There can be little doubt that very many important improvements made by landowners have yielded less than the ordinary rate of profit, just as peasant proprietors obtain a poor return by way of wages for their own labor. A landowner cultivating his own land has the whole margin of economic rent to fall back upon, but a farmer has to pay his rent as a first charge. Thus, it is possible, provided always that the land is cultivated in both cases with the same skill, that food would be cheaper if all the land were cultivated by the owner and not by tenants farming for a profit, and thus the fact that the American farmers pay no rent may account partially for the lower prices at which they sell their corn. (2) Again, the pure theory takes no account of the size of the portions into which the land is divided, nor of the kind of crops which are grown. But, when most of the land of a country is rented, both of these factors have to be considered, and it may be more convenient to the landowner to let the land with certain restrictions, which again indirectly operate on the price. (3) It has been well observed by Passy[2] that the principal effect of various land laws is to increase or diminish the amount of the gross produce, which in Ricardian phraseology would mean to extend or contract the margin of cultivation. It thus appears that it is not always true to say that the payment of rent makes no real difference to the general public, and that it is simply a necessary method of equalizing farmers' profits. At the same time, however, with the necessary qualifications, there is no doubt that price determines rent and not rent price, especially when prices are affected by foreign competition. Recently in Great Britain a striking example has been afforded both of the abandonment of inferior lands (the contraction of the margin) and of a heavy fall in rent under the influence of falling prices.

Progress and rent.

The hypothetical history implied in Ricardo's theory as to the effects of the progress of society upon the value of agricultural produce also requires some criticism, such as that given by the historian of agriculture and prices, Thorold Rogers. The theory assumes that in the first place population increases, and thus there is a greater demand for food, and that therefore the margin of cultivation extends and the price rises, and rent rises also. But, as Rogers observes, history shows that agricultural improvements of all kinds have first of all increased the amount of food, and thus allowed of an increase in population. It is worth noticing that in our own times an increasing population in rural districts (*e.g.*, the Highlands of Scotland and the west of Ireland) may indirectly tend to lower or destroy rents through minute subdivision. Ricardo's theory, however, accounts very well for the rise in the ground-rents of towns and cities, and it is there far more than in the rural districts that the unearned increment is to be found.

Value of mining produce.

The value of mining produce is determined generally in the same way as that of agricultural produce; but similar qualifications must be introduced. The theory is that both extensively and intensively the produce of mines is subject to the law of diminishing return, that the margin recedes as the price falls and extends as it rises, and that thus the price is determined by the most costly portion which it just pays to bring to market. And no doubt the main facts of the theory are correct; and recently the mines of Great Britain no less than its lands have illustrated the retrogression of the margin and the fall in rents. The principal point to observe is that mines are gradually quite exhausted.[3] In general the produce of mines is, like that of land, consumed in a comparatively short time, and thus the value is subject to fluctuations according to the conditions of the annual demand and supply.

Precious metals.

The peculiar durability of the precious metals, however, makes them in this respect differ widely from most mining produce. It is of course undeniable that (supposing coinage free) the value of standard coins will be equal to the value of the same amount of bullion, and, conversely, that the bullion will be equal in value to the same amount of coins. The older economists argued that the precious metals had their value determined by their cost of production under the most unfavorable circumstances, and then argued that in consequence the value of money (or coins) tended to be governed by the cost of production of bullion. If, however, it is remembered that the annual production does not probably amount to two per cent. of the quantity in the hands of man, that cost of production can only operate through actual or potential supply, and that in the case of money the increase must be real to affect prices, it will be readily seen that the value of bullion is determined by the general level of prices (or the value of money), and not that the value of money depends upon the value of the bullion. At the same time, however, it is true that, if prices become very high,—in other words, if the value of money, and thus of bullion, becomes very low,—then a check is placed upon production from the mines, and, conversely, with falling prices or a rise in the value of the precious metals mining for them is extended and encouraged. But the difference in the annual supply due to this influence will be small under present or similar conditions. On the whole, this case of the precious metals furnishes perhaps the best example of the way in which the cost of production can only act through the law of supply and demand.

---

[1] An excellent account of the economic theory of rent, in which recent criticisms from different points of view (*e.g.*, by P. Leroy-Beaulieu, Henry George, etc.) are examined, is *Land and its Rent*, by Francis A. Walker, London, 1884.

[2] *Systèmes de Culture en France.*

[3] Cp. Marshall's *Economics of Industry*, London, 1879, bk. ii. chap. iii. § 5.

Law governing value of joint products.

There is one other part of the general theory of value which requires some notice. Some articles can only be produced in conjunction with others (*e.g.*, hides and beef, wool and mutton), and some modification of the theory is needed to suit this case. The law deduced is that—The sum of the values must be equal to the joint expenses of production, and the relative values *inter se* are determined by demand and supply. Thus the Australian sheep-farmers will extend their sheep-farms so long as for wool and mutton together they obtain a fair profit, but the amount contributed by each portion will be determined by the relative demand. It is interesting to observe that in the progress of society the value of the meat has risen as compared with that of the hides and the wool. The same principle determines the kind of produce which will be raised from land, though the application is rather more difficult owing to rotation of crops, etc.

Theory of international values.

Much discussion has taken place recently on the question whether a distinct theory of international values is required. In the limits assigned to this article it is only possible to indicate the principal points in dispute. The "orthodox" theory, as held by Ricardo, Mill, and Cairnes, has been attacked by Cournot, Prof. Sidgwick, and others, and has been re-stated with admirable clearness and much original power by Prof. Bastable.[1] The best way to answer the question seems to be to make clear the assumptions on which the values of commodities produced within any "nation" are determined, and then to consider whether any change must be made when we bring in other nations. We are at once met with the difficulty, What is a "nation?" The orthodox answer appears to be that within any nation (for which the term "economic area" might perhaps be advantageously substituted) there is effective industrial and commercial competition. This appears to imply no more than is contained in the principle noticed above, that relative values tend to be equal to the normal expenses of production (*commercial* competition), and that the expenses tend to be proportioned to the real cost (*industrial* competition). The question then arises, Do these conditions not exist in international trade?

Comparative cost.

The answer appears to be, first, that commercial competition certainly holds good; for as soon as a trade is established the commodities will sell at the same prices in both countries (allowance being made for cost of carriage). It would plainly be absurd to say that the value of Manchester goods is determined by their expenses of production if they are consumed in England, but by something else if they are sent to India. If then there is any difference between domestic and international values, it must arise owing to the absence of effective industrial competition; that is to say, in the same country (or economic area) the real cost determines the expenses of production on account of the supposed perfect mobility of labor and capital, but between different economic areas these agents of production do not pass with sufficient readiness to secure a similar correspondence. It thus follows that a country may import articles which it could produce at less real cost, provided that it pays for these imports with exports which cost even less. A very striking example of this doctrine of *comparative cost*, as it is termed, is furnished by Victoria after the great gold discoveries. All kinds of produce were imported and paid for with gold, because there was less real cost involved in obtaining the gold to pay for imports than in making the articles. According to this theory every country will devote its labor and capital to its most productive uses; and, if by some new imports a domestic industry is checked or abolished, it is argued that the labor and capital will be devoted to increasing the exports so as to pay for the new imports. It must clearly be assumed as axiomatic that in the absence of loans, tributes, etc., imports can in the long run only be paid for by exports, and also that those articles will be exported which can be produced at the least comparative real cost. This theory then may be held to explain in a satisfactory manner the origin and development of international *trade;* but the question of *values* is still undetermined. Consistently with exports paying for imports many different rates of exchange are possible, and the particular rate actually adopted is said to depend entirely on reciprocal demand. And in an extreme case, in which new countries trade solely in articles of which each has a monopoly, this answer would seem to be correct; but, when we consider that under present conditions trading countries have many articles in common, and that a slight margin of profit suffices to expand or diminish an export trade, this answer seems too vague and unreal. The most probable solution seems to be that the rates of exchange will be so adjusted as to give to the exporters the ordinary rate of profits current in their respective countries. In general it is clear that the rate will be determined independently of the foreign trade, or at least that the foreign trade is only one factor to be considered. It is said, for example, that the annual value of the agricultural produce of the United Kingdom exceeds the total amount of the exports. If the rate of profit falls, a trade which before was impossible becomes possible. The opinion may be hazarded that the best way of explaining the general theory of international values would be to start with the foreign exchanges; but such an investigation is too technical and difficult for this place.

Reciprocal demand.

Foreign exchanges.

(J. S. N.)

VAMPIRE, a term, apparently of Servian origin (*vampir*), originally applied in eastern Europe to blood-sucking ghosts, but in modern usage transferred to one or more species of blood-sucking bats inhabiting South America.

In the first-mentioned meaning a vampire is usually supposed to be the soul of a dead man which quits the buried body by night to suck the blood of living persons. Hence, when the vampire's grave is opened, his corpse is found to be fresh and rosy from the blood which he has thus absorbed. To put a stop to his ravages, a stake is driven through the corpse, or the head cut off, or the heart torn out and the body burned, or boiling water and vinegar are poured on the grave. The persons who turn vampires are generally wizards, witches, suicides, and persons who have come to a violent end or have been cursed by their parents or by the church. But any one may become a vampire if an animal (especially a cat) leaps over his corpse or a bird flies over it. Sometimes the vampire is thought to be the soul of a living man which leaves his body in sleep, to go in the form of a straw or fluff of down and suck the blood of other sleepers. The belief in vampires chiefly prevails in Slavonic lands, as in Russia (especially White Russia and the Ukraine), Poland, and Servia, and among the Czechs of Bohemia and the other Slavonic races of Austria. It became specially prevalent in Hungary between the years 1730 and 1735, whence all Europe was filled with reports of the exploits of vampires. Several treatises were written on the subject, among which may be mentioned Ranft's *De Masticatione Mortuorum in Tumulis* (1734) and Calmet's *Dissertation on the Vampires of Hungary*, translated into English in 1750. It is probable that this superstition gained much ground from the reports of those who had examined the bodies of persons who had been buried alive though believed to be dead, and was based on the twisted position of the corpse, the marks of blood on the shroud and on the face and hands,—results of the frenzied struggle in the coffin before life became extinct. The belief in vampirism has also taken root among the Albanians and modern Greeks, but here it may be due to Slavonic influence.

---

[1] *Theory of International Trade.*

Two species of blood-sucking bats (the only species known)—*Desmodus rufus* and *Diphylla ecaudata*—representing two genera (see MAMMALIA, vol. xv., p. 420), inhabit the tropical and part of the subtropical regions of the New World, and are restricted to South and Central America. They appear to be confined chiefly to the forest-clad parts, and their attacks on men and other warm-blooded animals were noticed by some of the earliest writers. Thus Peter Martyr (Anghiera), who wrote soon after the conquest of South America, says that in the Isthmus of Darien there were bats which sucked the blood of men and cattle when asleep to such a degree as to even kill them. Condamine, a writer of the 18th century, remarks that at Borja (Ecuador) and in other places they had entirely destroyed the cattle introduced by the missionaries. Sir Robert Schomburgk relates that at Wicki, on the river Berbice, no fowls could be kept on account of the ravages of these creatures, which attacked their combs, causing them to appear white from loss of blood. The present writer, when in South and Central America, had many accounts given him as to the attacks of the vampires, and it was agreed upon by most of his informants that these bats when attacking horses showed a decided preference for those of a gray color. It is interesting to speculate how far the vampire bats may have been instrumental —when they were, perhaps, more abundant—in causing the destruction of the horse, which had disappeared from America previous to the discovery of that continent.

Although these bats were known thus early to Europeans, the species to which they belonged were not determined until about fifty years ago, several of the large frugivorous species having been wrongly set down as blood-suckers, and named accordingly. Thus the name *Vampyrus* was suggested to Geoffroy and adopted by Spix, who also considered that the long-tongued bats of the group *Glossophagæ* were addicted to blood, and accordingly described *Glossophaga soricina* as a very cruel blood-sucker (*sanguisuga crudelissima*), believing that the long brush-tipped tongue was used to increase the flow of blood. *Vampyrus spectrum*, L., a large bat inhabiting Brazil, of sufficiently forbidding aspect, which was long considered by naturalists to be thoroughly sanguivorous in its habits, and named accordingly by Geoffroy, has been shown by the observations of modern travellers to be mainly frugivorous, and is considered by the inhabitants of the countries in which it is found to be perfectly harmless. Waterton believed *Artibeus planirostris*, a common bat in British Guiana, usually found in the roofs of houses, and now known to be frugivorous, to be the veritable vampire; but neither he nor any of the naturalists that preceded him had succeeded in detecting any bat in the act of drawing blood. It fell to the lot of Charles Darwin to determine one of the blood-sucking species at least, and the following is his account of the circumstances under which the discovery of the sanguivorous habits of *Desmodus rufus* was made: "The vampire bat is often the cause of much trouble by biting the horses on their withers. The injury is generally not so much owing to the loss of blood as to the inflammation which the pressure of the saddle afterwards produces. The whole circumstance has lately been doubted in England; I was therefore fortunate in being present when one was actually caught on a horse's back. We were bivouacking late one evening near Coquimbo, in Chili, when my servant, noticing that one of the horses was very restive, went to see what was the matter, and, fancying he could detect something, suddenly put his hand on the beast's withers, and secured the vampire." (*Naturalist's Voyage Around the World*, p. 22).

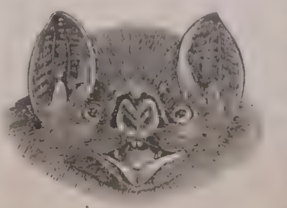

FIG. 1.—Head of *Desmodus rufus*, Weid.

Desmodus rufus, Weid, the common blood-sucking bat, is widely spread over the tropical and subtropical parts of Central and South America from Oaxaca to southern Brazil and Chili. It is a comparatively small bat, a little larger than the common noctule, the head and body about 3 inches in length, the forearm 2½, with a remarkably long and strong thumb; it is destitute of a tail, and has a very peculiar physiognomy, well represented in Fig. 1. The body is covered with rather short fur of a reddish brown color but varying in shade, the extremities of the hairs sometimes ashy. The teeth are peculiar and characteristic, admirably adapted for the purposes for which they are employed. The upper front teeth (incisors), of which there are only two, are enormously enlarged (see Fig. 2), and in shape obliquely triangular like small guillotines. The canines, though smaller than the incisors, are large and sharp; but the back teeth, so well developed in all other bats, are very small and reduced in number to two above and three below, on each side, with laterally compressed crowns rising but slightly above the level of the gum, their longitudinally disposed cutting edges (in the upper jaw) being continuous with the base of the canine and with each other. The lower front teeth (incisors) are small, bifid, in pairs, and are separated from the canines, with a space in front. The lower back teeth are narrow, like those in the upper jaw, but the anterior tooth is slightly larger than the others, and separated by a small space from the canines. Behind the lower incisors the jaw is deeply hollowed out to receive the extremities of the large upper incisors.

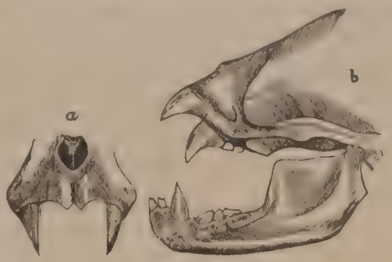

FIG. 2.—Teeth of *D. rufus*.

With this peculiar dentition there is associated as remarkable a departure from the general type in the form of the digestive apparatus. The exceedingly narrow œsophagus opens at right angles into a narrow, intestine-like stomach, which almost immediately terminates on the right, without a distinct pylorus, in the duodenum, but on the left forms a greatly elongated cæcum, bent and folded upon itself, which appears at first sight like part of the intestines. This, the cardiac extremity of the stomach, is, for a short distance to the left of the entrance of the œsophagus, still very narrow, but soon increases in size, till near its termination it attains a diameter quite three times that of the short pyloric portion. The length of this cardiac diverticulum of the stomach appears to vary from 2 to 6 inches, the size in each specimen probably depending on the amount of food obtained by the animal before it was captured.

The only other known species of blood-sucking bat, *Diphylla ecaudata*, Spix, inhabits Brazil, and appears to be much less abundant than *Desmodus rufus*, from which it is distinguished by its slightly smaller size, by the absence of a groove in the front of the lower lip, by the non-development of the interfemoral membrane in the centre, and by the presence of a short calcaneum (absent in *D. rufus*), but more particularly by the presence of an additional rudimentary back tooth (? molar) above and below, and by the very peculiar form of the lower incisors, which are much expanded in the direction of the jaws and pectinated, forming a semicircular row touching each other, the outer incisors being wider than the inner ones, with six notches, the inner incisors with three each.

Thus constituted, these bats present, in this extraordinary differentiation of the manducatory and digestive apparatus, a departure from the type of other species of the family (*Phyllostomidæ*) to which they belong unparalleled in any of the other orders of *Mammalia*, standing apart from all other mammals as being fitted only for a diet of blood, and capable of sustaining life upon that alone. Travellers describe the wounds inflicted by the large sharp-edged incisors as being similar to those caused by a razor when shaving: a portion of the skin is shaved off and, a large number of severed capillary vessels being thus exposed, a constant flow of blood is maintained. From this source the blood is drawn through the exceedingly narrow gullet—too narrow for anything solid to pass—into the intestine-like stomach, whence it is, probably, gradually drawn off during the slow process of digestion, while the animal, sated with food, is hanging in a state of torpidity from the roof of its cave or from the inner sides of a hollow tree. (G. E. D.)

VAN, a city of Asiatic Turkey, capital of a vilayet, is situated two miles to the east of the lake, to which it gives its name, in 38° 30′ N. lat. and 43° 18′ E. long. It lies on the ill-defined borderland between Armenia and Kurdistan, in an extremely fertile plain some 40 miles in circuit, which is described as one of the gardens of the East, whence the local saying: "Van in this world, heaven in the next." Its low flat-roofed houses are grouped irregularly at the southern base of a nummulitic limestone eminence, somewhat resembling a camel's back, which rises 100 feet sheer above the plain and is crowned by the so-called citadel, the fortifications of which are mostly in a dilapidated state. But it is naturally a position of great strength and of considerable strategic importance, standing at the junction of two military routes, which here diverge westwards through Músh and Kharpút to Asia Minor and southwards to Mosul and Mesopotamia, besides commanding the approaches to the Persian frontier at Kotúr and Bayezid. The town itself, which contains four mosques, two large churches, an Armenian bazaar, baths, and caravanserais, is enclosed within a double line of crenellated walls and ditches on the three sides not protected by the rock; and beyound these enclosures lies the suburban district of Baghlar, or the "Gardens." The population, estimated at from 30,000 to 35,000, are Turks, except about 2000 Armenians and a few hundred Mohammedan and Nestorian Kurds. Besides trade and agriculture, the inhabitants are engaged in a few industries, such as the making of coarse cotton chintzes, a highly prized goat-hair waterproof moire antique, a thick woollen cloth called *shayak*, and an excellent soap, prepared from the saline efflorescences of Lakes Van and Erchek, which consist in about equal proportions of the carbonate and sulphate of soda.

Armenian tradition derives the name of Van from an Armenian king who reigned a little before Alexander the Great and speaks of an older city founded by Semiramis (Shemiramagerd). This is of course fable; but the Vannic inscriptions (vol. xiii., p. 121–2) show that the region was the seat of an Armenian kingdom, whose native name was Biaina, as early as the 9th century B.C. In the isolated rock towering above the plain there are numerous galleries, flights of steps, crypts, and cuneiform rock inscriptions, one of which is trilingual, like that of Behistún, and like it relates the deeds of Xerxes, son of Darius. Others are in the Haikan or Old Armenian language; while for others scattered over the district a solution has been sought by Prof. Sayce with doubtful success in the present language of Georgia.

The vilayet of Van, one of the finest but also one of the least developed regions of Asiatic Turkey, lies on the Persian frontier between Erzerum (north) and Baghdad (south). It has an area of 15,000 square miles, with a population of over 1,000,000.

Lake Van.

Lake Van, called *Arsissa Palus* by the ancients, and also *Thospitis*, from its Armenian name Tosp, is 80 miles long and 30 broad, with a total area of 1500 square miles. Although of smaller extent than Lake Urmia, it contains a much larger volume of water owing to its much greater depth, which is at least 80 feet near Van and still more along the south side. The lake stands about 5400 feet above sea-level on the South Armenian plateau, which is encircled by the lofty ranges that bifurcate west and south from Ararat and culminate in the Sipan-Dagh (12,000 feet) on the north side of the lake. These mountains are clad with dense forests of beech, chestnut, ash, and walnut, while the broad fertile belt between their base and the lake is planted with melon gardens and orchards of plums, peaches, apricots, figs, and pomegranates, festooned with a vine which yields a palatable wine.

Lake Van, which is too brackish to be drinkable for man or beast, is inhabited by a species of blay or bleak, which abound especially about the mouths of the influents, and come to the surface when the spring floods spread over the heavier saline layers. This lake is a completely landlocked basin, or at least has no visible outlet. But the natives speak of underground channels through which it communicates southwestwards with the head-waters of the Tigris, attributing to the occasional obstruction of these channels the great oscillations of level that have undoubtedly occurred in past and recent times. In the 17th century and again about 1840 the water rose from 10 to 12 feet, and is even now (1888) rising. Lake Erchek perhaps marks its extreme eastern limit in former times. Lake Van is also indirectly connected with the Euphrates through the little Lake of Nazik, which lies west of the Sipan-Dagh, on the water-parting between the lacustrian and fluvial basins and which by a rare phenomenon sends emissaries to both. The narrow part of Lake Van, which runs for nearly 40 miles towards the northeast, and gives the lake somewhat the appearance of a frying-pan, is very shallow, and was once, according to tradition, a fertile plain. The lake is not regularly navigated. Scattered along the southeast shore are a few picturesque islets, one of which, Aktamar, is the seat of an Armenian patriarch.

VANADIUM, a rare element discovered in 1830 by Sefström, when analyzing a kind of iron obtained from the ores of Taberg in Sweden. Berzelius, in the course of an extensive investigation on vanadium, came to the conclusion that it is analogous to chromium, forming like it an acid trioxide, $VanO_3$, in which "Van" signifies 134.4[1] parts of a radical analogous to the $Cr = 52$ parts of chromium in chromic acid, CrO_3. He succeeded in isolating this radical, and, as it exhibited semi-metallic properties, he had no doubt that it was the element vanadium itself. His results were universally adopted as correct until Roscoe (in 1867) found that Berzelius's vanadium is an oxide containing $O_2 = 32$ parts of oxygen per Van, whence it followed that the presumed trioxide, $VanO_3$, is really a pentoxide, V_2O_5, where $V_2 = 2 \times 51.2 = 2$ atoms of the real element. Our present knowledge of vanadium is based chiefly upon his investigations. Of vanadium minerals, which are all very rare, we name two only,—mottramite, $(Pb,Cu)_3(VO_4)_2 + 2(Pb,Cu)(OH)_2$, and vanadinite, $3Pb_3(VO_4)_2 + PbCl_2$. This last is amorphous with apatite, which previous to Roscoe's discovery was difficult to explain. See CHEMISTRY, vol. v., p. 467.

Traces of vanadium are found in certain iron ores and in many other minerals. Roscoe utilized a kind of sandstone from Alderly Edge and Mottram in Cheshire which contains a small admixture of mottramite. Another suitable material is the "Bohnerz" of Steinlade and Haverloh, essentially a hydrated ferric oxide. For the extraction of vanadium from this latter mineral Wöhler recommends the following method. The finely powdered mineral is mixed with one-third of its weight of nitre and the mixture kept at a dull red heat for an hour. The ignited mass is powdered and lixiviated with water, which extracts the potash salts of the oxides V_2O_5, CrO_3, MoO_3, As_2O_5, P_2O_5, and SiO_2. The filtered solution is almost neutralized with nitric acid, but not completely, or else some of the V_2O_5 would be reduced by the nitrous acid to lower oxides; and the vanadic and most of the other acids named are precipitated as baryta salts by addition of chloride of barium. From the washed precipitate the acids are liberated by boiling dilute sulphuric acid, and the sulphate of baryta is filtered off. The solution is neutralized with ammonia, concentrated by evaporation, and, after cooling, kept in contact with a solid piece of sal-ammoniac more than sufficient to saturate the solution with this salt. Meta-vanadate of ammonia, $V_2O_5(NH_4)_2O$, being characteristically insoluble in sal-ammoniac solution, separates out as a yellowish crystalline precipitate. This is collected, washed with sal-ammoniac solution and after that with alcohol, and purified by re-crystallization or otherwise. The pure salt when heated to dull redness leaves the pentoxide, V_2O_5 (vanadic acid), as a red liquid, which freezes into a red-brown crystalline mass of sp. gr.,

---

[1] Calculated from our present constants.

3.35 (J. J. Watts). It dissolves in about 1000 parts of water, forming a yellow solution which reddens litmus. The pentoxide, though capable of uniting with strong acids, *e.g.*, with sulphuric into a salt, $V_2O_2(SO_4)_3$, behaves on the whole as an acid oxide analogous in its combining habits to phosphoric (see PHOSPHOROUS, vol. xviii., pp. 831–2, and CHEMISTRY, vol. v., p. 468). Solutions of vanadates are easily recognized: on addition of mineral acid they assume the yellow color characteristic of the pentoxide, and if the mixture is then kept in contact with zinc it passes through all shades of (intense) green till it ultimately assumes a lavender color. The solution then contains achloride corresponding to the oxide V_2O_2 (Berzelius's metal). It absorbs atmospheric oxygen with an extraordinary degree of avidity, assuming, in the absence of free acid, a dark brown color. An acidified vanadate solution, if shaken with peroxide of hydrogen and ether, furnishes a dark red reduction product, which passes into the ethereal layer. One part of vanadic acid in 40,000 parts of water can thus be rendered distinctly visible (Werther). If a mixture of the pentoxide and charcoal is heated in dry chlorine, it is converted into an oxychloride, $VOCl_3$ (trichloride of Berzelius), which distils over and may be purified by re-distillation over sodium. It is a canary-yellow mobile liquid, freezing below —15° C. and boiling at 126.7° C., and its sp. gr. at 14° C. is 1.841. Water decomposes it with formation of hydrochloric acid and pentoxide V_2O_5. If the vapor of this chloride is passed over red-hot charcoal in a current of chlorine, the tetrachloride VCl_4 is produced as a dark brown liquid, boiling at about 154° C. A mixture of the vapor of this chloride with hydrogen, when passed through a dull-red-hot tube, yields (more or less of "sesqui"-chloride, V_2Cl_6, and) the dichloride VCl_2, which, if pure, forms apple-green, mica-like, hexagonal plates. From this dichloride Roscoe for the first time prepared the true metal by heating it to redness in hydrogen gas, a simple enough method in theory, but in practice one of the most difficult of operations, because the dichloride is very difficult to prepare and highly hygroscopic, and because the metal is extremely prone to take up oxygen. Even the purest product which Roscoe succeeded in obtaining contained an appreciable admixture of oxide. Vanadium is a light gray powder, which under the microscope appears crystalline and exhibits a silvery lustre, sp. gr. = 5.5. Of its chemical properties the most remarkable is that it combines directly with nitrogen gas, N_2, into a bronze-colored nitride, VN.

Rare and expensive as vanadium is, it has found a practical application in the production of aniline black. The black is produced from aniline by the action of chloric acid, aided by the presence of some oxygen carrier. Sulphide of copper is usually employed; but, as Lightfoot found, a mere trace of vanadic acid (or vanadate of ammonia) acts more energetically than any other available agent. According to Witz, 1 part of vanadic acid suffices for 67,000 parts of aniline salt.

VANBRUGH, SIR JOHN (1666?–1726), dramatist and architect, was the son of a wealthy sugar-baker in Cheshire and grandson of a Protestant refugee of Ghent. From a passage in one of his letters to Tonson it might be supposed that he was born in the Bastille, though in what year is uncertain, probably in 1666. He was educated in France, but what he learnt there, whether architecture or merely that art of good-fellowship which he found to be the true Aladdin's lamp of social life, is a question that will be variously answered by those who, like Sir Joshua Reynolds, admire Blenheim and Castle Howard, and those who, like the wits of Vanbrugh's time, scoff at them. This, however, is certain, that after his return from the Continent to England what he did was, not to pursue architecture, but to work, with a gusto and a success that are humorous and exhilarating, the "Aladdin's lamp" above mentioned. His first step towards becoming a power in society was, of course, to enter the army. Perhaps, however, had he begun life in any other way his advance would have been just as rapid. For, strong as are social conditions, character is stronger still, and Vanbrugh's equipment—wit, tempered by good humor, a genuine feeling of comradeship, an exceedingly fine presence (according to Noble's description), and a winsome face (according to Kneller's portrait)—would, under any circumstances, have been irresistible. One of the points of difference between the dialogue in Vanbrugh's comedies and the dialogue in the comedies of Congreve is this: we feel that the characters in the *Relapse* and the *Confederacy* talk as Vanbrugh must have talked; we feel that the characters in the *Old Bachelor* and the *Way of the World* talk, not as Congreve talked, but as Congreve wrote. We feel that, while such dazzling sword-play as Congreve's would in society have chilled, even as it illumined the air, talk so hearty, good-humored, frank, and daring as that we get in Vanbrugh's plays would have made the fortune of any man of fashion, made it as certainly at a Roman supper party in the time of Augustus as at a London drinking-bout in the days of Queen Anne. It is no wonder then that he was a favorite, no wonder that the two best haters of the time, Swift and Pope, tried in vain to hate the "man of wit and honor," Vanbrugh. During the martial period of his life, Vanbrugh wrote the first sketches of the *Relapse* and the *Provoked Wife*. These he showed to Sir Thomas Skipworth, one of the shareholders of Drury Lane, and with fortunate results.

In 1695 he was offered—whether through the court interest which he had secured or whether because he really had acquired a knowledge of architecture in France is not known—the post of secretary to the commission for endowing Greenwich Hospital. He accepted the post, and by way of fulfilling his functions as an architect turned his attention to the amours of "Lord Foppington." His *Relapse or Virtue in Danger*, a sequel to Colley Cibber's *Love's Last Shift*, was produced at Drury Lane in 1697. When a comic dramatist of the school of Wycherley confesses that the fine gentleman of his play, "drinking his mistresses' health in Nantes brandy from six in the morning to the time he waddled on upon the stage in the evening, had toasted himself up to such a pitch of vigor" that something too outrageous even for such an audience seemed imminent, we may assume that he has enjoyed a satisfactory first night. The success was so triumphant that Montague, afterwards Lord Halifax, asked at once for the *Provoked Wife* for the theatre in Lincoln's Inn Fields, and—Skipworth waiving, for the advantage of Vanbrugh, his own claim upon the play—it was produced at that theatre in the following year. All that could be said in answer to those who condemned it on account of its unblushing libertinism was that Sir John Brute is sufficiently brutal to drive any woman into rebellion, and that since the glorious days of the Restoration a wife's rebellion and a wife's adultery were synonymous terms. The play was a complete triumph.

And now, having succeeded as a man of fashion, as an architectural commissioner, and as a comic dramatist of the school of Wycherley, Vanbrugh turned his attention to morals. Though *Æsop*—produced at Drury Lane in the same year as the *Provoked Wife*—was an adaptation of Boursault's dramatic sermon on the same subject, it was an improvement on the French play. As usual with Vanbrugh, who never did things by halves, he surpassed the Frenchman on that very point where the Frenchman had been pronounced unsurpassable. Just as in the *Relapse*, when he aspired to be merry, his merriment had entirely surpassed that of Cibber's play, of which his own was meant to be a sequel, and just as afterwards, when in Castle Howard and Blenheim he aspired to rival in massiveness the "thick rotundity of the earth," he laid on her a structure only a "few tons lighter than herself," so now, when he aspired to surpass the Frenchman in gravity, he achieved a kind of dulness compared with which the owl-like dulness of Boursault was as the wit of Voltaire. In a word, the humor of the piece lies in the fact that it was written by the author of the *Relapse* and the *Provoked Wife*. The play ran during a week only. Vanbrugh, accepting the failure with his usual good temper, seems then to have turned his attention completely to architecture; for the adaptation in 1700 of the *Pilgrim* of Beaumont and Fletcher, and the production in 1702 of *A False Friend*, could hardly have engaged his serious efforts at all, so perfunctory are they and so inferior to all that he had done before.

Castle Howard in Yorkshire, which he had built for the earl of Carlisle, was a great success so far as pleasing his patron went, who as a reward gave him yet another opening in life by presenting him,—the most ignorant man perhaps in England of heraldry, judging from the fun he made of the appointment,—with the tabard of Clarencieux king-at-arms. But, if the dangerous moment in every man's life is when he has just scored a brilliant success, it is especially so with genial glowing natures like Vanbrugh's. It seems to have been the success of Castle Howard that caused him to entertain the rash project of building a theatre, from his own design, for the acting of, his own plays. The joyous courage with which, having persuaded thirty people in the fashionable world to aid him in finding the money, and Congreve to aid him in finding the plays, he began to build in perfect unconsciousness of the danger before him is the only passage in his life which may be called pathetic, save of course his struggle with the "wicked woman of Marlborough." No doubt any architect who builds a theatre is always in danger of letting his ideas run riot in the wide field of experiment, but he who builds a theatre for his own plays seems doomed by the malice aforethought of fate. The magnitude of Vanbrugh's architectural ideas grew as the work went on, and with the ideas the structure grew till a theatre meant for the delicate *bijouterie* work of polite comedy seemed growing to the proportions of the Roman Colosseum. Whether Congreve endeavored to put a check upon his friend's architectural and authorial fervor does not appear. But it must be remembered that not only Vanbrugh's plays, but his own were to be acted there, and that, although Congreve was a man of great sagacity, no man not even he who pretended to set his gentility above his genius, is sagacious when confronted by the surpassing excellence of his own poems and plays.

When at length the time came to test the acoustics of the pile, it was found to be sadly defective. What changes were made to rectify the errors of structure does not appear. The theatre was opened to the public with an Italian opera, which was followed by three of Molière's comedies, and these by the *Confederacy*, Vanbrugh's masterpiece on the whole, though perhaps its finest scenes are not equal to the finest scenes in the *Relapse*.

Vanbrugh at last withdrew from the disastrous speculation; Congreve had already withdrawn. But a man to whom fortune had been so kind as she had been to Vanbrugh could hardly be depressed by any of her passing frowns. Queen Anne at once sent him abroad on an important state errand, and afterwards he was commissioned to build Blenheim. Upon the merits and demerits of this famous "hollowed quarry" there has been much conflict of opinion. As to the sarcasms by Swift, Walpole, Evans, and the rest, they are as nothing when set against Sir Joshua Reynolds's defence of Vanbrugh and his style. For in England the general sense for architecture seems to be even rarer than the general sense for poetry and painting. The truth is that Vanbrugh imported largely into architecture what in all the plastic arts should be allowed to fructify but sparsely, namely, literary ideas, and even these literary ideas of his seem to lack that fusion which we see in the works of the great masters. Hence, impressive as are the parts, they do not form an impressive whole. Blenheim, however, was a source of great sorrow to the kindly dramatist. Though Parliament had voted for the building of it, no provision had been made for the supplies. The queen while she lived paid them, and then Vanbrugh was left to the meanness of the duke of Marlborough and afterwards to the insolence of the "wicked woman," who did her best to embitter his life. Besides Castle Howard and Blenheim, he built many other country mansions, such as Grimsthorpe and Duncombe Hall in Yorkshire, Eastbury in Dorsetshire, Seaton-Delaval in Northumberland, King's Weston near Bristol, Oulton Hall in Cheshire, etc.

About the end of 1710 Vanbrugh married Henrietta Maria, daughter of Colonel Yarborough of Haslington, and four years afterwards, at the accession of George I., he was knighted. He afterwards wrote again for the stage, and the unfinished fragment left at his death, which took place on 26th March, 1726, at his house in Scotland Yard, London, shows that his powers remained to the last as fine as ever.

In order to find and fix Vanbrugh's place among English comic dramatists, an examination of the very basis of the comedy of repartee inaugurated by Etheredge would be necessary, and, of course, such an examination would be impossible here. It is chiefly as a humorist, however, that he demands attention.

Given the humorous temperament—the temperament which impels a man to get his enjoyment by watching the harlequinade of life, and contrasting it with his own ideal standard of good sense, which the harlequinade seems to him to mock and challenge—given this temperament, then the quality of its humorous growths depends of course on the quality of the intellectual forces by means of which the temperament gains expression. Hence it is very likely that in original endowment of humor, as distinguished from wit, Vanbrugh was superior to Congreve. And this is saying a great deal: for, while Congreve's wit has always been made much of, it has, since Macaulay's time, been the fashion among critics to do less than justice to his humor, —a humor which, in such scenes as that in *Love for Love* where Sir Sampson Legend discourses upon the human appetites and functions, moves beyond the humor of convention and passes into natural humor. It is, however, in spontaneity, in a kind of lawless merriment, almost Aristophanic in its *verve*, that Vanbrugh's humor seems so deep and so fine, seems indeed to spring from a fountain deeper and finer and rarer than Congreve's. A comedy of wit, like every other drama, is a story told by action and dialogue, but to tell a story lucidly and rapidly by means of repartee is exceedingly difficult, not but that it is easy enough to produce repartee. But in comic dialogue the difficulty is to move rapidly and yet keep up the brilliant ball-throwing demanded in this form, and without lucidity and rapidity no drama, whether of repartee or of character, can live. Etheredge, the father of the comedy of repartee, has at length had justice done to him by Mr. Gosse. Not only could Etheredge tell a story by means of repartee alone: he could produce a tableau too; so could Congreve, and so also could Vanbrugh, but often—far too often—Vanbrugh's tableau is reached, not by fair means, as in the tableau of Congreve, but by a surrendering of probability, by a sacrifice of artistic fusion, by an inartistic mingling of comedy and farce, such as Congreve never indulges in. Jeremy Collier was perfectly right therefore in his strictures upon the farcical improbabilities of the *Relapse*. So farcical indeed are the tableaux in that play that the broader portions of it were (as Mr. Swinburne discovered) adapted by Voltaire and acted at Sceaux as a farce. Had we space here to contrast the *Relapse* with the *Way of the World*, we should very likely come upon a distinction between comedy and farce such as has never yet been drawn. We should find that farce is not comedy with a broadened grin—Thalia with her girdle loose and run wild—as the critics seem to assume. We should find that the difference between the two is not one of degree at all, but rather one of kind, and that mere breadth of fun has nothing to do with the question. No doubt the fun of comedy may be as broad as that of farce, as is shown indeed by the celebrated Dogberry scenes in *Much Ado about Nothing* and by the scene in *Love for Love* between Sir Sampson Legend and his son, alluded to above; but here, as in every other department of art, all depends upon the quality of the imaginative belief that the artist seeks to arrest and secure. Of comedy the breath of life is dramatic illusion. Of farce the breath of life is mock illusion. Comedy, whether broad or genteel, pretends that its mimicry is real. Farce, whether broad or genteel, makes no such pretence, but by a thousand tricks, which it keeps up between itself and the audience, says, "My acting is all sham, and you know it." Now, while Vanbrugh was apt too often to forget this the fundamental difference between comedy and farce, Congreve never forgot it, Wycherley rarely. Not that there should be in any literary form any arbitrary laws. There is no arbitrary law declaring that comedy shall not be mingled with farce, and yet the fact is that in vital drama they cannot be so mingled. The very laws of their existence are in conflict with each other, so much so that where one lives the other must die, as we see in the drama of our own day. The fact seems to be that probability of incident, logical sequence of cause and effect, are as necessary to comedy as they are to tragedy, while farce would stifle in such an air. Rather it would be poisoned by it, just as comedy is poisoned by what farce flourishes on, that is to say, inconsequence of reasoning—topsy-turvy logic. Born in the fairy country of topsy-turvy, the logic of farce would be illogical if it were not upside-down. So with coincidence, with improbable accumulation of convenient events,—farce can no more exist without these than comedy can exist with them. Hence we affirm that Jeremy Collier's strictures on the farcical adulterations of the *Relapse* pierce more deeply into Vanbrugh's art than do the criticisms of Leigh Hunt and Hazlitt. In other words, perhaps the same lack of fusion which mars Vanbrugh's architectural ideas mars also his comedy. (T. W.)

VAN BUREN, MARTIN (1782–1862), eighth president of the United States, was the son of a thrifty farmer, and was born 5th December, 1782, at Kinderhook, Columbia, New York State, on the banks of the Hudson. He was educated at the village academy, and, entering on the study of law at the age of fourteen, was called to the bar in 1803. Possessing in addition to his other abilities a peculiar power of winning personal trust and influence, his rise both in his profession and political reputation was rapid. In 1808 he was chosen surrogate of Columbia county, and in 1812 a member of the State senate. From 1815 to 1819 he was attorney-general of the State, and during this period came to be recognized as the ruling spirit of the new Democratic junto known as the Albany regency. In 1821 he was chosen to the United States senate and the same year was elected a member of the convention for revising the State constitution, in which, though advocating an extension of the franchise, he opposed universal suffrage. In 1828 he was elected governor of New York State. From March, 1829, to April, 1831, he was secretary of state in the administration of President Jackson, of whom he was the chief political adviser. During the recess he was appointed minister to England; but, on the ground that he had previously shown a too submissive attitude towards that country, and also a tendency to be influenced in his foreign predilections by home politics, the senate refused to ratify the appointment. In the following year he was, however, chosen vice-president of the United States, and in 1837 he succeeded Jackson as president. He entered upon office at the time of a severe commercial crisis (see UNITED STATES), and, although the methods he adopted to deal with it were in themselves admirable, the financial strain which existed during his term of office weakened for a time the influence of his party. Besides the establishment of the independent treasury system, Van Buren's name is associated with the preemption law giving settlers on public lands the preference in their purchase. On the expiry of his term of office he was again, in 1840, nominated for the presidency, but lost by a large majority. In 1844 a majority of the delegates to the Democratic convention were pledged to support him, but on account of his opposition to the annexation of Texas, they allowed a motion to be introduced making a two-thirds vote necessary for nomination. This he failed to obtain and his name was withdrawn. In 1848 he was nominated by the anti-slavery section of his party, but the split caused the defeat of both Democratic candidates. The remainder of his life was spent chiefly in retirement on his estate at Kinderhook. In 1853–55 he went on a European tour. He died at Kinderhook, 24th July, 1862. His *Inquiry into the Origin and Course of Political Parties in the United States* was published by his sons in 1867.[1]

See W. Allen Butler, *Martin Van Buren, Lawyer, Statesman, and Man*, New York, 1862.

VANCOUVER, GEORGE (*c.* 1758–1798), English navigator, was born about 1758. He entered the navy at the age of thirteen, and accompanied Cook in his second (1772–74) and third (1776–79) voyages of discovery. After serving for several years on the Jamaica station, Vancouver was appointed to command an expedition to the northwest coast of America, the object being to take over from the Spaniards their territory in that region, and to explore the coast from 30° N. lat. round to Cook's Inlet (or river as it was then called), with a view to the discovery of an eastward passage to the great lakes in the British dominions. The special point which he had to ascertain was whether the Strait of Juan de Fuca really was a strait. Vancouver, accompanied by Lieutenant Broughton, left Falmouth on 1st April, 1791, and, after spending some weeks at the Cape, made for the coast of Australia, where a very careful survey of the southwest coast was made, especially of King George's Sound, the value of which as a harbor Vancouver pointed out. He next made for Dusky Bay, New Zealand. After a short stay, he proceeded northeast, discovered the little island of Oparo (27° 36′ S. lat. and 144° 12′ W. long.) by the way, and on 30th December reached Tahiti, where he was again joined by Lieutenant Broughton, who meanwhile had discovered Chatham Island. After staying about three weeks at Tahiti and several weeks at the Sandwich Islands, Vancouver on 18th April, 1792, sighted the west coast of North America (California, then known as New Albion) in 39° 27′ N. lat. Here he proceeded to examine the coast up to 52° 18′ N. lat. with minute care, surveying all inlets and navigating the passage through Juan de Fuca which separates the Island of Vancouver fram the mainland. Most of February and March, 1793, was spent again at the Sandwich Islands, with the natives of which Vancouver had much intercourse, and in the affairs of which he took much interest. In April he resumed his exploration of the coast, which he examined and surveyed as far north as 56° N. lat. Part of the autumn was spent in visiting the Spanish settlements in New California, and surveying the coast and coast region as far south as 35° N. lat. From January to the beginning of March Vancouver's headquarters were again at the Sandwich Islands, the cession of which to Great Britain he accepted, though the cession seems never to have been officially ratified. Quitting the Sandwich Islands again about the middle of March, 1784, Vancouver made direct for Cook's Inlet by Tchernigoff Island and Kodiak Island. Cook's Inlet was carefully explored and the fact established that it was not a river. The coast eastwards and southwards was surveyed as far as the limit of the former voyages. After spending some time about Nootka and visiting some parts of the coast, Vancouver set out homewards in the middle of October, 1794. Several points were examined and surveyed on the west coast of America on the way southwards, including Cape St Lucas, the southern point of Lower California. After touching at Cocos Island and making a somewhat careful examination of the Galapagos Islands, Vancouver continued his voyage by way of Cape Horn, finally entering the mouth of the Shannon on 13th September, 1795. He immediately set about the preparation of the narrative of his voyage, but died at Petersham in Surrey, 10th May, 1798, before he had quite completed his task. Under the care of his brother the narrative was published in 1798 (3 vols. 4to), with a folio volume of magnificent maps and plates.

---

[1] [In the Albany Regency, which included Silas Wright and W. L. Marcy, the astuteness of Van Buren rendered him the chief spirit as founder and methodizer. It was an extension of the perfect organization of Tammany Hall maintained during election intervals, to the State, and the alliance between the two marked the separation of Van Buren from the interests of De Witt Clinton, and secured to the former the epithets of "the fox" and "the sage of Kinderhook." He was one of the most adroit politicians produced in the United States, but it requires an apologist to make him out a great statesman. Yet he was identified with the advocacy of measures which in later hands became honorable achievements. Thus in the State Senate he urged the abolition of imprisonment for debt, except in cases of fraud, and, supported by R. M. Johnson, of Kentucky, he pursued the same object in the Senate of the United States. As governor of New York he urged the "Safety Fund Law" to secure the public from loss on the failure of banks,—a measure which long maintained the bank-note currency of the State near or at par and was reproduced, at least in principle, in Secretary Chase's scheme for the redemption of National Bank notes. As president he favored making ten hours the standard of a day's labor in the government navy yards, and, although his administration marks the transition of his party to modern Democracy and was stormy, he never exercised the veto power. His "Independent Treasury System," designed to separate the government from banking interests, is of disputed utility and remains still a measurable test of strict party fealties. His opposition to the annexation of Texas defeated his nomination for the presidency in 1844, and his place at the head of the Free Soil party cost Lewis Cass a defeat in 1848, and Van Buren his further political career, while it marked the entrance into national politics of the anti-slavery agitation, which eventually placed the government in the hands of Lincoln. The two most recent and favorable biographies of Van Buren are that of W. O. Stoddard in *Lives of the Presidents* (1888), and of E. M. Shepard in the *Statesmen Series* (1888).

Of his sons the eldest, ABRAHAM, graduated at West Point in 1827, and served as a major in the Mexican war. JOHN (1810–1866) graduated at Yale, practiced law at Albany, where he became attorney-general for the State in 1845, and two years later removed to New York city. He belonged to the Free-Soil Democracy, and advocated the exclusion of slavery from the Territories. He died at sea (13th October) on his way home from Europe.—AM. ED.]

Vancouver's work on the west and northwest coast of America was of the highest character, and has formed the basis of all subsequent surveys. His zeal led him to take an active share in all operations, and the hardships he thus suffered tended no doubt to shorten his life. He was a man of great tact, humanity, generosity, and uprightness of character.

VANCOUVER ISLAND, which is included in the territory of British Columbia, lies in a northwest and southeast direction parallel with the coast. From Washington Territory (U.S.) on the south it is separated by Juan de Fuca Strait, which leads into the Gulf of Georgia and Johnstone's Strait on the east of the island, Queen Charlotte Sound entering this last from the northwest. These channels vary from 5 to 80 miles in width. The island extends from 48° 20′ to 51° N. lat. and from 123° to 128° 30′ W. long. Its length is about 250 miles and its breadth varies from 10 to 70. The area is estimated at from 12,000 to 16,000 square miles; but the island has never been completely surveyed. The coast-line generally is precipitous. The west coast is much broken by bays and fringed with numerous reefs and islands, which render navigation somewhat dangerous. Barclay Sound on the southwest, Nootka Sound behind Nootka Island on the west, and Quatseenough Sound on the northwest send branches into the heart of the island. The east coast is much less broken, though the channel separating it from the mainland is studded with islands. Vancouver generally is mountainous, with peaks rising from 6000 to 9000 feet. There are some level areas on the southeast coast, while in the interior a few narrow well-watered valleys are suitable for agriculture. Short streams run down both coasts, and the island is dotted with lakes,—Buttle and Dickson in the centre, Cowichan in the south, and Niinkish in the north. The mountains, much broken, run generally along the length of the island, the highest peaks (estimated at 9000 feet) being southeast of Nootka Sound, while farther to the north are Victoria Peak (7484 feet) and Mount Alston (6500) feet. To the south of Buttle Lake, Mount Albert Edward rises to 6968 feet. The mountains in the south of the island are generally lower.

Plate III.

The island is essentially a mountain range composed of metamorphic and trappean rocks, fringed by a belt of Carboniferous limestones and other sedimentary deposits. Among the metamorphic and erupted rocks are gneiss and killas or clayslate, permeated by quartz veins, quartz and hornblende rocks, compact bituminous slate, highly crystalline felspathic traps, and semicrystalline concretionary limestone. Among the sedimentary rocks are sandstones and stratified limestones, fine and coarse grits, conglomerates, and fossiliferous limestones, shales, etc., associated with seams of coal. The country is strewn with erratic boulders and other marks of Glacial action. So far as is known at present the chief mineral resource is coal, which is worked in large quantities at Nanaimo on the east coast, and in quality is reputed the best on the whole Pacific coast. While limited areas in the southeast of the island and in the inland valleys are well adapted to agriculture (about 300,000 acres in all), and while farming is carried on to some extent, the country is too mountainous ever to develop agriculture on any large scale. The mountains are, however, covered with forests, mainly the Douglas pine, yielding splendid supplies of timber. These forests, with its coal and its fisheries, may be regarded as the chief resources of the island. The climate of Vancouver, especially in the south, is wonderfully mild for the latitude, as mild as that of Great Britain, with drier summers. The mean temperature of December at Victoria, in the south of the island, is about 38° Fahr., while that of July is 53°. A rainfall of 35.87 inches in the year has been recorded at Esquimault. In the northern parts and in the west the climate gets much more severe, and there the rainfall is greater than on the south and east coasts. Cereals of all kinds, all fruits of the temperate zone, pulse, and vegetables flourish on the patches suited to agriculture, while cattle and sheep can be easily reared in small numbers. The population of the island in 1881 was 9991, of whom 5925 lived in the city of Victoria. In 1887 the population was estimated at 25,090 (19,000 whites and Chinese, and 6000 Indians).

The chief city of the island is VICTORIA (*q.v.*). Three and a half miles to the west of Victoria is the town of Esquimault at the head of Parry Bay. There has been a British Admiralty station here for many years, the harbor having an average depth of from 6 to 8 fathoms. There are Government offices, two churches, a public school, and various other buildings. The Canadian Government has constructed a dry dock, 450 feet long, 26 feet deep, and 65 feet wide at the entrance. The completion of the Canadian Pacific Railway renders Esquimault of increasing importance. Seventy-three miles north of Victoria and connected with it by railway is the town of Nanaimo, the centre of the coal mining industry; the average output of coal in the five years ending 1887 was 250,000 tons per annum. The mines employ about 1100 men. There are a good harbor and wharves. The population in 1887 was estimated at 4000. There are smaller communities in the island, mainly in the south corner. Sixty miles northwest of Nanaimo is Comox, the chief centre of the lumber industry. On the mainland opposite Nanaimo, on a peninsula to the south of Burrard's Inlet, a city named Vancouver has recently been formed (incorporated 1886) at the terminus of the Canadian Pacific Railway.

History.—Vancouver Island was discovered by Juan de Fuca in 1592. In 1778 Captain Cook roughly surveyed the coast, this work being extended by Captain Vancouver, who surveyed the Strait of Juan de Fuca and the Gulf of Georgia. The first settlement on the island was made by the Hudson's Bay Company on the site of Victoria in 1843. Six years later Vancouver Island was constituted a colony. Its union with British Columbia was effected in 1866.

VANDALS. The Vandals, one of the leading Teutonic nations that overthrew the Roman Empire, were of the Low German stock and closely allied to the Goths. We first hear of them in the time of Pliny and Tacitus as occupying a district nearly corresponding to Brandenburg and Pomerania. From thence, in the 2d century, they pressed southwards to the confines of Bohemia, where they gave their name to the mountains now called the Riesengebirge. After a century of hostile and desultory operations against the Roman empire, having been signally defeated by Aurelian (271), they made peace with Rome, one of the conditions being that they should supply 2000 *fœderati* to the imperial army. Sixty years later they sustained a great defeat from the Goths under their king Geberich, after which they humbly sought and obtained permission from Constantine to settle as Roman subjects within the province of Pannonia. Here they remained seventy years, and during this

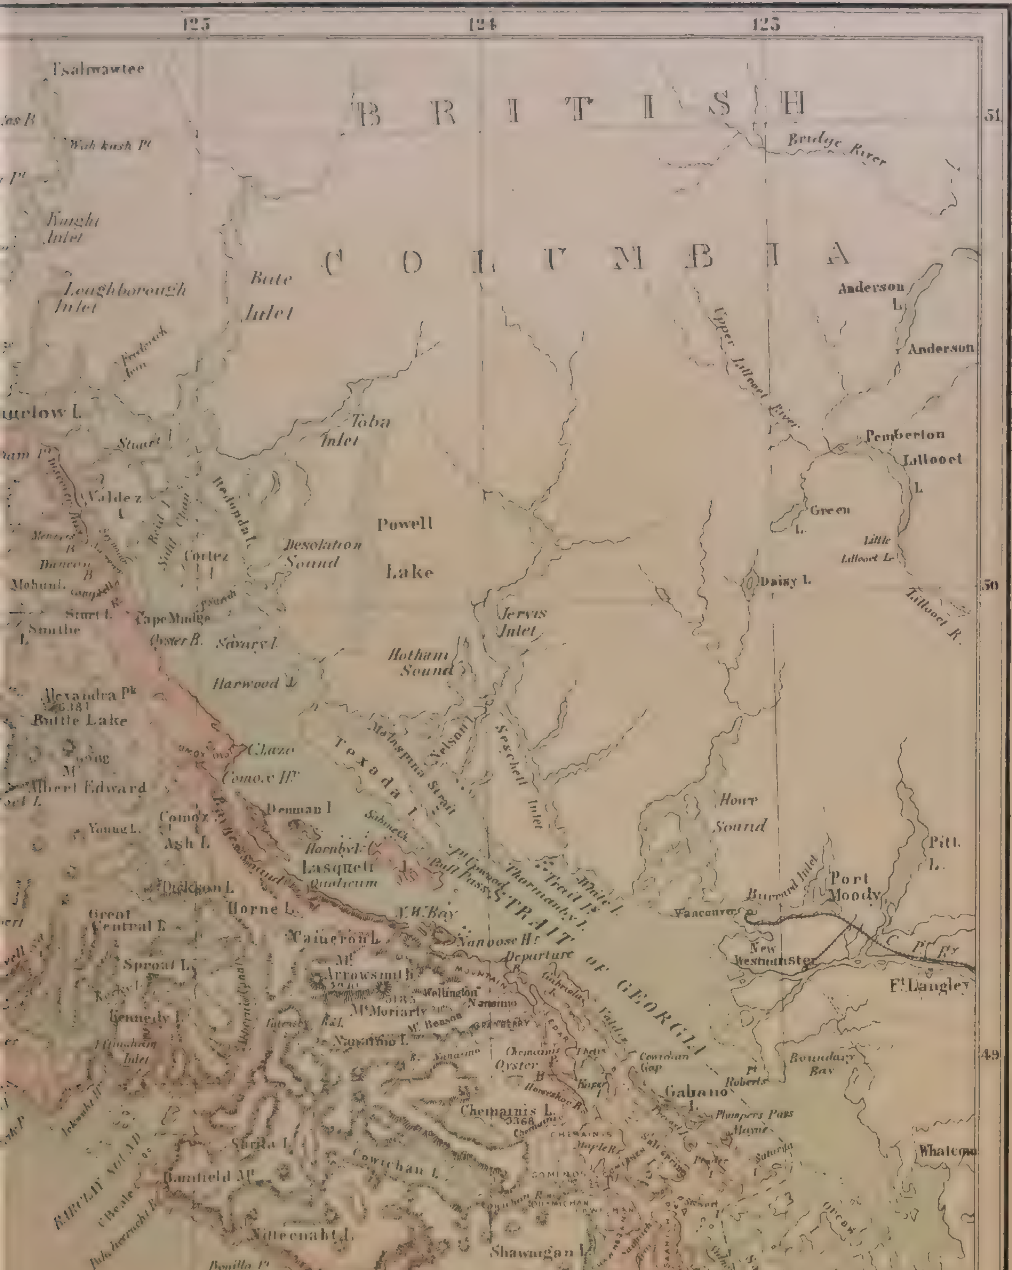
R ISLAND. PLATE III.



period they probably made some advances in civilization and became Christians of the Arian type. In 406, when the empire under Honorius was falling into ruin, they crossed the Rhine and entered Gaul. Stilicho, the chief adviser of Honorius, who was a man of Vandal extraction, was accused by his enemies of having invited them into the empire, but this is probably a groundless calumny. In Gaul they fought a great battle with the Franks, in which they were defeated with the loss of 2000 men, and their king Godigisclus was slain. In 409 his son Gunderic led them across the Pyrenees. They appear to have settled in Spain in two detachments. One, the Asdingian Vandals, occupied Galicia, the other, the Silingian, Andalusia. Twenty years of bloody and purposeless warfare with the armies of the empire and with their fellow-barbarians, the Goths and the Suevi, followed. The Silingian Vandals were wellnigh exterminated, but their Asdingian brethren (with whom were now associated the remains of a Turanian people, the Alans, who had been utterly defeated by the Goths) marched across Spain and took possession of Andalusia.

In 428 or 429 the whole nation set sail for Africa, upon an invitation received by their king from Bonifacius, count of Africa, who had fallen into disgrace with the court of Ravenna. Gunderic was now dead and supreme power was in the hands of his bastard brother, who is generally known in history as Genseric, though the more correct form of his name is Gaiseric. This man, short of stature and with limping gait, but with a great natural capacity for war and dominion, reckless of human life and unrestrained by conscience or pity, was for fifty years the hero of the Vandal race and the terror of Constantinople and Rome. In the month of May, 428 (?), he assembled all his people on the shore of Andalusia, and numbering the males among them from the graybeard down to the newborn infant found them to amount to 80,000 souls. The passage was effected in the ships of Bonifacius, who, however, soon returning to his old loyalty, besought his new allies to depart from Africa. They, of course, refused, and Bonifacius turned against them, too late, however, to repair the mischief which he had caused. Notwithstanding his opposition the progress of the Vandals was rapid, and by May, 430, only three cities of Roman Africa—Carthage, Hippo, and Cirta—remained untaken. The long seige of Hippo (May, 430, to July, 431), memorable for the last illness and death of St. Augustine, which occurred during its progress, ended unsuccessfully for the Vandals. At length (30th January, 435) peace was made between the emperor Valentinian III. and Genseric. The emperor was to retain Carthage and the small but rich proconsular province in which it was situated, while Hippo and the other six provinces of Africa were abandoned to the Vandal. Genseric observed this treaty no longer than suited his purpose. On the 19th of October, 439, without any declaration of war, he suddenly attacked Carthage and took it. The Vandal occupation of this great city, the third among the cities of the Roman empire, lasted for ninety-four years. Genseric seems to have counted the years of his sovereignty from the date of its capture. Though most of the remaining years of Genseric's life were passed in war, plunder rather than territorial conquest seems to have been the object of his expeditions. He made, in fact, of Carthage a pirate's stronghold, from whence he issued forth, like the Barbary pirates of a later day, to attack, as he himself said, "the dwellings of the men with whom God is angry," leaving the question who those men might be to the decision of the elements. Almost alone among the Teutonic invaders of the empire he set himself to form a powerful fleet, and was probably for thirty years the leading maritime power in the Mediterranean. Genseric's celebrated expedition against Rome (455), undertaken in response to the call of Eudoxia, widow of Valentinian, was only the greatest of his marauding exploits. He took the city without difficulty, and for fourteen days, in a calm and business-like manner, emptied it of all its movable wealth. The sacred vessels of the Jewish temple brought to Rome by Titus, are said to have been among the spoils carried to Carthage by the conqueror. Eudoxia and her two daughters were also carried into captivity. One of the princesses, Eudocia, was married to Huneric, eldest son of Genseric; her mother and sister, after long and tedious negotiations, were sent to Constantinople.

There does not seem to be in the story of the capture of Rome by the Vandals any justification for the charge of wilful and objectless destruction of public buildings which is implied in the word "vandalism." It is probable that this charge grew out of the fierce persecution which was carried on by Genseric and his son against the Catholic Christians, and which is the darkest stain on their characters. This persecution is described with great vividness, and no doubt with some exaggeration, by the nearly contemporary Victor Vitensis. Churches were burned; bishops and priests were forced by cruel and revolting tortures to reveal the hiding-places of the sacred vessels; the rich provincials who were employed about the court, and who still adhered to the Catholic faith, were racked and beaten, and put to death. The bishops were almost universally banished, and the congregations were forbidden to elect their successors, so that the greater part of the churches of Africa remained "widowed" for a whole generation. In 475, at the very close of Genseric's life, by a treaty concluded with the Eastern emperor, the bishops were permitted to return. There was then a short lull in the persecution; but on the death of Genseric (477) and the accession of Huneric (a bitter Arian, made more rancorous by the orthodoxy of his wife Eudocia) it broke out again with greater violence than ever, the ferocity of Huneric being more thoroughly stupid and brutal than the calculating cruelty of his father.

On the death of Huneric (484) he was succeeded by his cousin Gunthamund, Genseric having established seniority among his own descendants as the law of succession to his throne. Gunthamund (484–496) and his brother Thrasamund (496–523), though Arians, abated some of the rigor of the persecution, and maintained the external credit of the monarchy. Internally, however, it was rapidly declining, the once chaste and hardy Vandals being demoralized by the fervid climate of Africa and the sinful delights of their new capital, and falling ever lower into sloth, effeminacy, and vice. On the death of Thrasamund, Hilderic (523–531), the son of Huneric and Eudocia at length succeeded to the throne. He adhered to the creed of his mother rather than to that of his father; and, in spite of a solemn oath sworn to his predecessor that he would not restore the Catholic churches to their owners, he at once proceeded to do so and to recall the bishops. Hilderic, elderly, Catholic, and timid, was very unpopular with his subjects, and after a reign of eight years he was thrust into prison by his warlike cousin Gelimer (531–534).

The wrongs of Hilderic, a Catholic, and with the blood of Theodosius in his veins, afforded to Justinian a long-coveted pretext for overthrowing the Vandal dominion, the latent weakness of which was probably known to the statesmen of Constantinople. A great expedition under the command of Belisarius (in whose train was the historian Procopius) sailed from the Bosphorus in June, 533, and after touching at Catana in Sicily finally reached Africa in the beginning of September. Gelimer, who was strangely ignorant of the plans of Justinian, had sent his brother Tzazo with some of his best troops to quell a rebellion in Sardinia (that island as well as the Balearic Isles forming part of the Vandal dominions), and the landing of Belisarius was entirely unopposed. He marched rapidly towards Carthage and on the 13th of September was confronted by Gelimer at Ad Decimum, 10 miles from Carthage. The battle did not reflect any great credit either on Byzantine or Vandal generalship. It was in fact a series of blunders on both sides, but Belisarius made the fewest and victory remained with him. On the 14th of September, 533, the imperial general entered Carthage and ate the feast prepared in Gelimer's palace for its lord. Belisarius, however, was too late to save the life of Hilderic, who had been slain by his rival's orders as soon as the news came of the landing of the imperial army. Still Gelimer with many of the Vandal warriors was at liberty. On the return of Tzazo from Sardinia a force was collected considerably larger than the imperial army, and Gelimer met Belisarius in battle at a place about 20 miles from Carthage, called Tricamarum (December, 533). This battle was far more stubbornly contested than that of Ad Decimum, but it ended in the utter rout of the Vandals and the flight of Gelimer. He took refuge in a mountain fortress called Pappua on the Numidian frontier, and there, after enduring great hardships in the squalid dwellings of the Moors, surrendered to his pursuers in March, 534. The well-known stories of his laughter when he was introduced to Belisarius, and his chant, "Vanitas Vanitatum," when he walked before the triumphal car of his conqueror through the streets of Constantinople, probably point to an intellect disordered by his reverses and hardships. The Vandals who were carried captive to Constantinople were enlisted in five squadrons of cavalry and sent to serve against the Parthians under the title "Justiniani Vandali." Four hundred escaped to Africa and took part in a mutiny of the imperial troops which was with difficulty quelled by Belisarius (536). After this the Vandals disappeared from history. The overthrow of their kingdom undoubtedly rendered easier the spread of Saracen conquest along the northern shore of Africa in the following century. In this as in many other fields Justinian sowed that Mohammed might reap.

Authorities.—Procopius, *De Bello Vandalico*, a first-rate authority for contemporary events, must be used with caution for those which happened two or three generations before him. Consult especially i. 5 for the land settlement of Genseric, and also Victor Vitensis and Possidius (*Vita Augustini*) for the persecution of the Catholics. The chroniclers Idatius, Prosper, Victor Tunnunensis supply some facts. The *Chronicon* of Isidor adds little to our knowledge and is absurdly wrong in its chronology. Of modern treatises that of Papencordt (*Gesch. d. Vandal. Herrschaft in Afrika*) is the most complete. Consult also Dahn (*Könige der Germanen*, part I.), Gibbon (chaps. xxxiii. and xli.), and Hodgkin (*Italy and her Invaders*, vols. ii. and iii.). (T. H.)

VAN DER HELST. See HELST.

VANDEVELDE, ADRIAN (1639–1672), animal and landscape painter, a brother of William Vandevelde (see below), the marine painter, was born at Amsterdam in 1639. He was trained in the studio of Jan Wynants, the landscape painter, where he made the acquaintance of Philip Wouwerman, who is believed to have aided him in his studies of animals, and to have exercised a powerful and beneficial influence upon his art. Having made exceptionally rapid progress, he was soon employed by his master to introduce figures into his landscape compositions, and he rendered a similar service to Hobbema, Ruysdael, Verboom, and other contemporary artists. His favorite subjects are scenes of open pasture land, with sheep, cattle, and goats, which he executed with admirable dexterity, with much precision of touch and truth of draughtsmanship, and with clear silvery coloring. He painted a few small but excellent winter scenes with skaters, and several religious subjects, such as the Descent from the Cross, for the Roman Catholic church in Amsterdam. In addition to his paintings, of which nearly two hundred have been catalogued, he executed about twenty etchings, several of which appear from their dates to have been done in his fourteenth year. They are simple but pleasing in tonality, and are distinguished by great directness of method, and by delicacy and certainty of touch. Adrian Vandevelde died at Amsterdam in January, 1672.

VANDEVELDE, WILLIAM (1633–1707), the younger, marine painter, a son of William Vandevelde, the elder, also a painter of sea-pieces, was born at Amsterdam in 1633. He was instructed by his father, and afterwards by Simon de Vlieger, a marine painter of repute at the time, and had achieved great celebrity by his art before he came to London. In 1674 he was engaged by Charles II., at a salary of £100 [$486], to aid his father in "taking and making draughts of sea-fights," his part of the work being to reproduce in color the drawings of the elder Vandevelde. He was also patronized by the duke of York and by various members of the nobility. He died in London on 6th April, 1707.

It seems probable that most of Vandevelde's finest works were executed before his residence in England, for they represent views off the coast of Holland, with Dutch shipping. His best productions are delicate, spirited, and finished in handling, and correct in the drawing of the vessels and their rigging. The numerous figures are tellingly introduced, and the artist is successful in his renderings of sea, whether in calm or storm. His later productions are less carefully finished, and less pure and transparent in color. Vandevelde was a most prolific artist: in addition to his paintings, of which Smith catalogues about three hundred and thirty, he executed an immense number of drawings, sketches, and studies, which are prized by collectors.

VAN DIEMEN'S LAND. See TASMANIA.

VAN DYCK, SIR ANTHONY (1599–1641), painter, was born in Antwerp on 22d March, 1599. Though the name of Van Dyck is frequently met with in the list of Antwerp painters, Anthony's pedigree cannot be traced beyond his grandparents, who were silk mercers of some standing. He was the seventh of twelve children of Francis Van Dyck, an Antwerp tradesman in good circumstances, and not, as has been asserted, a painter on glass at Bois-le-Duc. His mother, Maria Cupers, who died when he was scarcely eight years of age, seems to have attained a certain degree of excellence in art needlework. Of the boy's early education nothing is known. He was little over ten when he was apprenticed to Henry Van Balen, the painter of many delicate little pictures, also an occasional collaborator of Rubens, and the master of Snyders. From a document discovered some twenty years ago in the state paper office at Brussels, relating to a lawsuit between a picture dealer and an Antwerp churchman, which arose out of the sale, in 1660, of a series of Apostle's heads ascribed to Van Dyck, it appears that, as far back as 1615, Van Dyck had worked independently, with pupils of his own, and that his pictures were greatly valued by artists and amateurs.[1] Before he was nineteen (February, 1618) Van Dyck became a full member of the Antwerp guild of painters; and some idea of his ability at the time may be gained from the excellent portraits of an old lady and gentleman, ascribed till quite recently to Rubens, in the Dresden gallery (Nos. 854 and 855). Dated 1618, they were originally entered as works of Van Dyck, and, as Prof. Woermann observes, are undoubtedly the same as those spoken of by Mols in his MS. annotations on Walpole's *Anecdotes*, now in the library at Brussels. But the same admiration cannot be accorded to the earliest religious composition known to have been painted by him—Christ Falling under the Cross, in St. Paul's at Antwerp. This picture, of some ten life-size figures, still preserved in the place for which it was originally destined, distinctly proves that from the outset of his career Van Dyck's power of conception was vastly inferior to his refined taste as a portrait painter. At first sight it would seem also that with him, as with most other Flemish painters of the period, every conception, whether sacred or profane, needed to be cast in the mould of Rubens. It would be too much, however, to assert that Van Dyck at this time stood under the guidance of that master; their association indeed does not seem to have begun until 1619, and Bellori (1672), who got his information from Sir Kenelm Digby, Van Dyck's bosom friend, tells us that he was first employed in making drawings (probably also chiaroscuros) for the use of the great master's engravers, and that among works of the kind one of the first was the Battle of the Amazons (1619).

---

[1] Prof. Woermann has identified several of the Apostle's heads here spoken of with some paintings in the gallery at Dresden.

In 1620 we know that Van Dyck was working with Rubens, for on 20th March, in making arrangements with the Antwerp Jesuits for the decoration of their church, the great master is allowed to avail himself of his pupil's assistance, and obtains for him the promise of a picture. This proof of Van Dyck's personal reputation is fully confirmed (17th July) by a correspondent of the earl of Arundel, who speaks of Van Dyck as a young man of one and twenty whose works are scarcely less esteemed than those of his master, and adds that, his relations being people of considerable wealth, he could hardly be expected to leave his home. Van Dyck was, however, thus persuaded, for on 28th November Sir Toby Mathew mentions the artist's departure to Sir Dudley Carleton, adding that he is in receipt of an annual pension of £100 [$486] from the king. There is evidence of Van Dyck's presence in London till the end of February, 1621. He is first mentioned in the order-books of the Exchequer on the 17th of that month as receiving a reward of £100 [$486] "for special service by him performed for His Majesty," and on the 28th, "Antonio van Dyck, gent., *His Majesties servant*, is allowed to travaile 8 months, he havinge obtayneid his Ma^{ties} leave in that behalf, as was signified by the E. of Arundell." What Van Dyck did in London is not known. Among his numerous paintings still preserved in English houses one only is admitted as belonging to the period of this first visit, a full-length portrait of James I. in the royal collection. That he was at the time a portrait painter of the rarest merit may easily be seen from his own likeness of himself when still quite young and beardless, in the National Gallery (London), in the Pinakothek at Munich, and in the private collections of the duke of Grafton and Sir Richard Wallace. In this last admirable specimen the young painter has represented himself in the character of Paris. Early paintings by Van Dyck are certainly not scarce in British galleries; and at Dulwich there is his admirable Samson and Delilah, wrongly ascribed to Rubens.

Van Dyck is supposed to have profited by his leave of absence to visit Paris and The Hague; but it is much more probable that the eight months were spent in Antwerp, where Rubens was greatly in need of his assistance for the church of the Jesuits. After this Van Dyck most probably returned to London and remained there till the end of 1622, when his father died. The precise date of his departure for Italy—perhaps at the beginning and certainly in the course of 1623—has not been ascertained. But he is known to have left with Rubens a considerable number of paintings, most of which have been identified in Madrid, Berlin, Dresden, etc., and show that study, as well as advice, had long since made the painter acquainted, through Rubens, with those principles of picturesque expression which he was now about to see exemplified so splendidly in the works of the Venetian and Genoese schools. His previous acquaintance with many excellent examples of Titian, Tintoretto, and others in Rubens's own collection can alone account for the remarkably glowing tints of Van Dyck's earliest paintings. In fact, such works as the Martyrdom of St. Peter (Brussels), the Crowning with Thorns (Berlin), the Betrayal of Christ (Madrid and Lord Methuen), St. Martin Dividing his Cloak (Windsor Castle),—a magnificent production, generally ascribed to Rubens, but easily identified through Van Dyck's admirable sketch at Dorchester House,—incontestably prove that, in point of coloring, Venice at this moment stood higher in his predilection than Antwerp.

It is unnecessary to dwell on a number of tales connected with Van Dyck's early life, all of which have on closer examination proved to be apocryphal; but one story has been too frequently told to be altogether ignored. At the very outset of his Italian journey the inflammable youth was captivated by the beauty of a country girl, and for the love of her painted the altar-piece still to be seen in the church at Saventhem near Brussels, in which he himself is supposed to be represented on a gray horse, given by Rubens to his pupil. It is now known, however, that the picture was commissioned by a gentleman living at Saventhem (to the charms of whose daughter Van Dyck in reality seems not to have been altogether insensible), and a closer study makes it almost certain that it was executed after, not before, his Italian journey. On a reduced scale, and with the omission of two or three figures, the St. Martin at Saventhem is a reproduction of the picture at Windsor Castle.

No master from beyond the Alps ever took up a higher position than Van Dyck among the most celebrated representatives of Italian art. Study, as a matter of course, had been one of his principal objects. No doubt can be entertained as to the great influence exerted by the works of Titian and Paul Veronese in the development of his genius; still the individuality of the painter remains a striking feature of what may be termed his Italian works, especially portraits. Their peculiar character seems to originate even more in the stateliness of the personages he was fortunate enough to have as sitters than in any desire to follow individual predilection or prevailing fashion. As in later years Van Dyck gives us a striking picture of the higher classes in England, so at this stage he makes us acquainted with Italian beauty and style; and at no other period is his talent more advantageously shown than in some of the glorious portraits he painted at Rome, at Florence, and above all at Genoa. At Rome he resided with Cardinal Guido Bentivoglio, who had been papal nuncio in Flanders from 1607 to 1617. For this patron were painted several works of very great importance, the most renowned being the prelate's own portrait, now in the Pitti Palace at Florence. Another work was a Crucifixion, representing Christ dying on the cross with uplifted eyes. Most probably the picture spoken of by Bellori ought to be identified with the admirable edition now in the gallery at Naples, catalogued as "Scuola di Van Dyck," unsurpassed by any of those at Antwerp, Paris, Vienna, Rome, or elsewhere. Besides these he painted religious subjects and portraits, several of which are reckoned among his finest examples, such as the portrait of Francis Duquesnoy, the famous sculptor, belonging to the king of the Belgians, and those of Sir Robert Shirley and his wife, in Persian attire, now at Petworth.

Bellori tells us of Van Dyck's prepossessing appearance, of his elegance and distinction, altogether so different from the habits of his compatriots in Rome, who formed a jovial "gang," as they termed their association. Van Dyck seems to have kept out of their way, and incurred in consequence such annoyance as made his stay in Rome much shorter than it would otherwise have been. In the company of Lady Arundel, who tried to persuade him to return to England, he travelled to Turin, and perhaps produced some of the paintings now in the royal gallery there, such as the spirited portrait of Thomas of Savoy on his splendid black charger. But he was eager to reach Genoa, where Rubens had worked with great success some twenty years before, and where his Antwerp friends, Luke and Cornelis de Wael, for many years resident in Italy, now were. Van Dyck remained their guest for several months, and their portraits, now in the Pinacoteca Capitolina at Rome (engraved by W. Hollar from the monochrome at Cassel), may be supposed to have been one of his first Genoese productions. Though several of the palaces of the "superb" city no longer retain their treasures, and among the specimens of Van Dyck's genius still left too many have been greatly injured by cleaning and retouching, Genoa can still boast of a good number of his most attractive productions, portraits of the beautiful ladies and haughty cavaliers of the noble houses of Doria, Brignole Sale, Pallavicini, Balbi, Cattaneo, Spinola, Lommelini, and Grimaldi. It would scarcely be possible to speak too highly of such works as the portrait of the lady in white satin and the Durazzo children at the Durazzo Palace, the Balbi children at Panshanger, the Marchesa Balbi at Dorchester House, the equally beautiful portraits of the Lommelini and of the knight in black armor, buff jacket, and boots in the national gallery at Edinburgh, or the Marchesa Brignole Sala at Warwick Castle. Van Dyck's "Genoese manner" is a current expression, and indeed his Genoese portraits are remarkable for their richness of tonality and what might be called royal splendor, perhaps never before attained in works of the kind. This we may suppose to have had its origin, not only in the recent study of Titian (Van Dyck having, it is said, first spent some time at Venice), but also in decorative necessities,—the size of the palatial galleries and the rich hues of the Genoese velvets, on which these portraits were to find their place, obliging the painter to find a most uncommon strength of contrast. It must also be acknowledged that the beauty and distinction of Van Dyck's models are greatly enhanced by a splendor of costume entirely different from the dulness then prevalent almost everywhere else. In Italy, moreover, he found the reality of those gorgeous backgrounds,—flowing draperies, beautiful gardens, ornamental pillars, marble terraces and balustrades,—which elsewhere must be regarded as fictions merely. Here, finally, he was for the first time called upon to paint some of his grandest equestrian portraits, and the often-recurring gray steed with flowing mane (an admirable study of which belongs to Lord Brownlow) was first employed for the portrait of Antonio Giulio Brignole (still at Genoa) and for another picture which we may suppose to represent the same personage at Stafford House. As with Rubens, Titian seems to have been paramount in Van Dyck's regard. Copies in great number we know he possessed of the master's best works, and several little sketches in the British Museum bear proof of his devout study of the great Venetian. Some of Van Dyck's earlier paintings, religious and mythological,—the Tribute Money (Brignole Palace), Holy Family (Turin), Virgin and Saints (Louvre), Virgin (Grosvenor House), Martyrdom of St. Lawrence (S. Maria dell' Orto, Venice), Bacchanal (Lord Belper), engraved at Genoa as early as 1628, St. Sebastian (Edinburgh),—are certainly Titianesque in the extreme. Still the master's individuality is not obliterated, and the gallery at Parma has a Virgin with the Infant Asleep which may be termed a marvel of realistic simplicity.

Van Dyck is said to have sailed from Genoa to Palermo and there to have painted several persons of rank, including the viceroy, Emmanuel Philibert of Savoy. While in Sicily he became acquainted with the painter Sofonisba Anguisciola (or Angussola), who was then over ninety years of age and blind; and he was wont to say he had received more valuable information from a blind woman than from many a seeing man. No important works of Van Dyck are now to be found in Sicily. Bellori tells us that a plague broke out and compelled him to leave abruptly, taking with him an unfinished picture of St. Rosalia, destined for a confraternity of that name, and which was completed in Genoa. The composition was repeated in Antwerp for the Bachelor's Brotherhood, a picture now in Vienna. Van Dyck most probably remained in Genoa till 1627, and here in all likelihood he met and painted the sculptor George Petel, whose portrait is now in Munich, and who was frequently employed by Rubens; the De Jodes, father and son, the celebrated engravers, who are represented together in a masterly portrait in the Capital at Rome, the companion picture to the brothers De Wael; and Nicholas Laniere, musician-in-chief to Charles I., a painting spoken of in Van der Dort's catalogue as "done beyond the seas." Laniere was in Italy precisely at this time and it was through his portrait (now at Windsor Castle), Walpole assures us, that Van Dyck attracted the notice of Charles I.

Embarking for Marseilles, Van Dyck is said to have stopped at Aix with Peiresc, the famous scholar and friend of Rubens, and thence to have gone to Paris, where most probably he painted the beautiful portrait of Langlois the print-seller (belonging to Mr. W. Garnett), a work still influenced by Italian reminiscences, and had the opportunity of meeting Callot, Simon Vouet, and Dupuy, the king's librarian,—all of whose portraits where engraved from his drawings in Antwerp. According to some authors, he also worked in Holland before returning to his native town; but the supposition rests entirely on two portraits in the museum at The Hague, dated 1627 and 1628, and representing a lady and gentleman, with the Sheffield arms. The lady is easily identified by a well-known print by Clouwet as Anne Wake. The Wake family resided in Antwerp, and both portraits may have been painted there. There is no recorded proof of Van Dyck's return to Antwerp before 6th March, 1628. One of his sisters had died in a convent the year before, and he now made a will in favor of Susan and Isabella, two other sisters, also nuns. That Van Dyck was in Antwerp on 18th May is proved by a letter from Lord Carlisle to Buckingham (Sainsbury, CIII.), but it is stated in Bullart's *Académie*, published in 1682, that he returned again to London in 1629, without, however, attracting the king's attention. It is very likely that Lady Arundel's endeavors to get him back to England were now successful, and that the beautiful portrait of Lord Thomas, at Stafford House, belongs to this period.

Great as may have been the strength of Italian reminiscence, from the moment Van Dyck again trod Flemish soil the influence of Rubens became predominant, and we can scarcely doubt that a competition speedily arose between master and pupil. At this period churches and convents were numerous and richly endowed; and the number of pictures, stained glass windows, and elaborate carvings in Belgian churches before the French conquest was enormous. Hardly fifty years had elapsed since these buildings had been stripped of their artistic treasures, and the devout were now eager once more to adorn them with productions of the greatest painters. Hence Van Dyck's share could be very copious without in any degree interfering with the vast undertakings assigned to Rubens. The latter was also absent for many months in 1629 and 1630, so that Van Dyck was for a time the first master in the Netherlands. Among the earliest works after his return to Antwerp, we find the Crucifixion, given to the Dominican nuns, in accordance with the wish expressed by the painter's dying father, and now in the Antwerp museum. The figures are life-size, and at the foot of the cross, besides a weeping angel, are St. Catherine of Siena and St. Dominic. Neither in type nor in general effect does it suggest the master's immediately preceding works. As a new feature we observe a kind of elegance, not entirely free from mannerism, which is often conspicuous with Van Dyck even when the technical excellence commands our warmest admiration. Inspiration, as Waagen observes, was far more limited with Van Dyck than with Rubens. His truly delicate nature led him to restrain his conceptions within the bounds of an academic evenness, generally more pleasing to the uninitiated than the strength of expression which sometimes imparts a sort of violence to the works of Rubens. To Van Dyck's second—more justly speaking third—manner belong some of his best religious works. The Crucifixion in the cathedral at Mechlin is termed by Sir Joshua Reynolds one of the finest pictures in the world. Other Crucifixions are in St. Michael's at Ghent (sketches in Lord Brownlow's collection and the Brussels museum) and in the church at Termonde. Still finer are the two works painted for the Antwerp Jesuits and now at Vienna,—the Blessed Herman Joseph Kneeling before the Virgin and St. Rosalia Crowned by the Infant Saviour. To this period likewise belong the celebrated Elevation of the Cross at Courtrari and the St. Augustine in Ecstasy, in the church of the Jesuits at Antwerp; the general effect of this last, it must be acknowledged with Reynolds, is inferior to the beautiful engraving by De Jode, and also to the earl of Northbrook's magnificent sketch. At Dulwich we find the first idea of the composition, with many interesting differences. It may be a matter of individual preference to pronounce Van Dyck's Flemish portraits superior to those of an earlier period; but nobody can fail to admit that, technically speaking, they indicate a further step towards perfection. The darkness of the Genoese portraits has vanished; broad daylight now freely illuminates the model, and such works as the portraits of Cornelius Van der Geest (National Gallery, London) and Ambrogio Spinola (Rev. W. H. Wayne) are perhaps as close to material excellence as any painting could be. The full-length likenesses of Philip Le Roy (1630) and his wife (1631) (at Manchester House) and of Mary Louisa of Tassis (Prince Liechtenstein, Vienna) are not only the finest examples of the master's talent, but deserve to rank among the most beautiful portraits ever painted. The Snyders at Castle Howard is regarded by Waagen as not inferior to the most celebrated Raphæls, Titians, or Holbeins; and of almost equal excellence are the Wife of Colin de Nole in the Munich gallery, the Lady and her Daughter at the Louvre and the Lady in Black at Cassel.

Rapidly rising to honor and wealth, Van Dyck shared with Rubens the official title of court painter, and his numerous portraits of the Infanta in her monastic garb (Paris, Vienna, Turin, Parma, etc.) bear testimony to the great favor in which he stood with her. When Mary de' Medici, after her flight from France, took up her residence in Brussels (1631), she honored Van Dyck, as well as Rubens, with repeated visits, and several times called upon him to paint her likeness, as well as those of Gaston of Orleans and his wife Margaret of Lorraine, and several of the personages of their court. From Gerbier's letters we learn that Van Dyck at this time was contemplating another journey to England, and was very anxious to be commissioned by the infanta and the queen of France to take over their portraits as presents for the king and royal family. He soon travelled to The Hague to paint the prince and princess of Orange and their son. Quite at the beginning of 1632 Constantine Huygens, who was then living at The Hague, inscribes in his diary, "Pingor a Van Dyckio." When, towards the end of March, Van Dyck sailed for England, he took all these portraits with him, as we learn from an account of the 8th of August, 1632 (Carpenter's *Pictorial Notices*). Dutch authors speak of a visit paid by Van Dyck to Frans Hals at Haarlem, and of a portrait of the latter through which the Antwerp master was at once recognized by his Dutch colleague. An engraving of a portrait of Hals after Van Dyck seems to confirm the story.

In undertaking this new journey to London, Van Dyck was assured of success, for Gerbier's letters show that the king had personally desired his presence. As early as March, 1629, Endymion Porter, one of the gentlemen of the king's bedchamber, had been commissioned to order a picture from Van Dyck, Rinaldo and Armida. The composition is well known through De Ballu's first-rate engraving, and the canvas now belonging to the duke of Newcastle, may be looked upon as one of the master's finest creations. Rubens was in London at the time the picture arrived, and to him we may in a great measure attribute the realization of Van Dyck's plans and the exceptional favors bestowed upon him almost from the day of his arrival in London. Besides the title of painter in ordinary, and the grant of an annual pension of £200 [$972], he received the honor of knighthood after a residence of less than three months at court (5th July, 1632). Van Dyck rapidly achieved popularity among the higher classes, and, as Walpole says, his works are so frequent in England that to most Englishmen it is difficult to avoid thinking of him as their countryman.

His refined nature is strikingly illustrated in his admirable interpretation of English beauty and style. And, if Van Dyck be compared to Mytens and Cornelius Janssen, the most distinguished painters employed by the English court immediately before him, few artists, whether in England or elsewhere, have more richly endowed their models with distinction of feature and elegance in bearing. To him may be applied what Opie says of Titian, "that he combines resemblance with dignity, costume with taste, and art with simplicity." We are particularly struck with the thorough and immediate identification of his talent with local tastes and exigencies. Charles I. and Henrietta Maria, although pictured by several other painters, are known to posterity exclusively through Van Dyck, not from a greater closeness of resemblance to the original, but from a particular power of expression and bearing, which, once seen, it is impossible to forget. Lodged at the expense of the crown, with a summer residence at Eltham Palace, Van Dyck was frequently honored with the visits of the king at his studio at Blackfriars. Portraits now followed each other with a rapidity scarcely credible to those unacquainted with the artist's method. In fact, his mode of living and his love of pleasure sufficiently explain his great need of money. During the first year of his presence in England he painted the king and queen a dozen times. The first of these noble portraits is the admirable full length of Charles I., with the queen and their two eldest children, at Windsor Castle. The style he adopted in England is generally termed his third manner; we might better say his fourth, as he already had a very particular style before he set out on his Italian journey. De Piles gives us some account of Van Dyck's methods at this period of his career. He began with a small sketch on gray paper with black and white chalks, or a monochrome in oils. This study was passed on to assistants in order to be copied on the required scale. When the clothes were sufficiently advanced by the pupils from those sent by the model, as well as the background and accessories, the master was enabled in a few sittings of an hour each to complete the work. Van Dyck excelled in painting the hands; he is said to have kept special models for this part of his work. It need hardly be said that a system of this kind, although employed by Rubens for his larger creations, was exceedingly ill adapted to portrait painting. In Van Dyck's later productions we too often detect marks of haste, as if the pencil were becoming a mere implement of trade.

Nearly the whole of 1634 and 1635 were spent by Van Dyck in the Netherlands.[1] The archduchess died on 1st December, 1633, and Van Dyck naturally wished to get his official title renewed by her successor, Ferdinand of Austria, brother of Philip IV. That Van Dyck's residence in Antwerp was only to be temporary is shown by the power given to his sister Susan for the administration of his affairs in Belgium (14th April, 1634). On the arrival of the new governor Van Dyck was immediately called upon to paint his likeness, a picture now in the Madrid gallery, where the same personage is also represented by Rubens and Velazquez. Several other portraits of Ferdinand, either in his cardinal's robes or in military dress, by Van Dyck, occur elsewhere. One on horseback was exhibited at the Grosvenor Gallery, London, in 1887 as the duke of Alva (the property of Mr. S. Kynaston Mainwaring). Van Dyck was greatly in demand at this time, and his prices were correspondingly high, as the Antwerp municipality found when they asked for a portrait of the late infanta to decorate one of the triumphal arches for the reception of the new governor. The most important of Van Dyck's works, at any rate as a portrait painter, belong to this period. The picture representing in life size the members of the Brussels corporation, which was destroyed by fire during the siege of 1695, is spoken of with intense admiration by several writers. Bullart, for instance, is very enthusiastic about its fine color and lifelike qualities. Among the religious paintings of undisputed excellence belonging to the same period are the Adoration of the Shepherds in the church at Termonde, and the Deposition, where the body of Christ rests upon the lap of the Virgin, in the Antwerp museum. Among the portraits are the admirable full length of Scaglia, the king's frequent agent in the Netherlands (at Dorchester House; a replica in the museum at Antwerp), the equestrian portrait of Albert of Arenberg (Arenberg Palace at Brussels), and a portrait of the same nobleman on foot, in the black velvet Spanish dress with golden chamberlain's key (long said to be Rubens) at Althorpe, the full length of Helena Fourment, Rubens's second wife (at St. Petersburg), the beautiful duchess of Havre, Mary Clara de Croy, signed and dated 1634 (Mr. Ayscough Fawkes, and other members of the same family (at Munich), Thomas of Savoy (at Berlin), an admirable half length of a lady in black (in the Belvedere at Vienna), and above all the grandiose picture in which John of Nassau is represented at full length, with his wife and children (at Panshanger). Several portraits of Brussels and Antwerp magistrates must also be mentioned, the most important being John Van Merstraeten, a Brussels lawyer (at Cassel).

---

[1] It is not generally known that his brother, an Antwerp priest, had been called over by the queen to act as her chaplain.

After being chosen honorary president of the Antwerp guild of St. Luke, Van Dyck returned to London before the end of 1635. In spite of the vast number of his later portraits, some of them deserve to be ranked among the most celebrated of his productions. The royal children in the gallery at Turin (1635), the portraits of Charles I. in the Louvre and in the National Gallery, London, the picture of the Pembroke family at Wilton House, Sir George and Sir Francis Villiers, and the earls of Bristol and Bedford, at Althorpe, as well as those of Francis Russell, fourth earl of Bedford, and Anne Carr, his consort, at Woburn Abbey (1636), all belong to the years immediately following the master's return from the Netherlands.

He now married Lady Mary Ruthven, daughter of Sir Patrick Ruthven and granddaughter of the earl of Gowrie. There are several portraits of her by her husband, the most important being in the Munich gallery, in which she is represented in white satin, playing on the violoncello. She is also said to figure as the Virgin in a picture belonging to Lord Lyttleton. There is a capital engraving of her by Bolswert. In another picture, said to be Mary Ruthven (belonging to Mr. J. C. Herford), an exceedingly handsome lady is represented as Herminia Putting on Clarinda's Armor. There can be no doubt as to the model having been Margaret Lemon, a celebrated beauty, whose portrait was engraved by W. Hollar and J. Morin and painted by Van Dyck at Hampton Court. "She was," says M. Law, in his excellent catalogue of this gallery, "the most beautiful and celebrated, though far from being the only mistress of Van Dyck. The great artist, in fact, loved beauty in every form, and found the seduction of female charms altogether irresistible. She lived with him at his house at Blackfriars." The precise date of Van Dyck's marriage has not been ascertained. It was probably towards the end of 1639. The union is said to have been promoted by the artist's friends in order to save him from the consequence of his pernicious way of living. Margaret Lemon resented the event most cruelly, and tried to maim Van Dyck's right hand.

Van Dyck found few occasions in England to paint anything but portraits. He seems to have been decidedly underrated by the king and queen as an imaginative painter. At the very time of his employment on the beautiful portraits of Henrietta Maria, destined to serve as models for Bernini's bust, Gerbier was secretly negotiating with Jordaens, by order of Charles, for the decoration of the queen's apartments at Greenwich (1639). There exists at Belvoir Castle a sketch by Van Dyck representing a procession of the knights of the Garter, a really grandiose composition, engraved by Cooper. We know from Bellori that Van Dyck had suggested through his friend Sir Kenelm Digby, for the banqueting room at Whitehall, a series of decorations illustrating the history of the order of the Garter, and that the king had been much pleased with the idea. The plan, however, failed through the excessively high price asked by the painter, and perhaps also because the king had thought of having the work done in tapestry. Van Dyck's pension was five years in arrear, and, instead of £560 [$2721,60], he received finally, besides his pension, only £200 [$972].

When the news of Rubens's death reached London (June, 1640) Van Dyck contemplated a return to his native country, and a letter from Ferdinand of Austria to Philip IV. speaks of his intended journey to Antwerp on St. Luke's Day (18th October). Rubens had left unfinished a series of paintings commanded by the king of Spain, and from correspondence published by Professor Justi we learn that Van Dyck had been thought of to give them the finishing touch. But he absolutely refused to finish them. It was then agreed that he should paint an independent canvas destined to complete the series. Van Dyck was delighted with this order, and Ferdinand tells his brother that he returned to London in great haste "to make preparations for his change of residence; possibly," adds the letter, "he may still change his mind, for he is stark mad." Whether Van Dyck found it possible to work during his short stay in the Netherlands is a matter of doubt. In the museum at The Hague are six medallion portraits of Constantine Huygens and his children, dated 1640. They have till lately been ascribed to Van Dyck, but are now said to be by Adrian Hanneman, a Dutchman, and one of his ablest assistants. In any case they are of small importance. Most authors suppose that Van Dyck's principal object in travelling to the Continent was to be entrusted with the decoration of one of the galleries of the Louvre. There may be some truth in this, for Mariette speaks of a letter he saw, written by Claude Vignon, the French painter, in January, 1641, asking Langlois for an introduction to Van Dyck, who was then in Paris. Unfortunately the great painter was thwarted in his aspirations. His health was beginning to fail. After his return to London he was frequently obliged to interrupt his work; and a letter written (13th August) from Richmond by Lady Anne Roxburgh to Baron W. van Brederode at The Hague, states that the portraits of the Princess Mary had been greatly delayed through Van Dyck's illness, and that the prince's (William II. of Orange) would be ready in eight days. "As Van Dyck intends leaving England in the course of ten or twelve days at latest," she adds, "he will take the paintings himself to the princess of Orange." These portraits, now in the museum at Amsterdam, are the last Van Dyck painted in England. They are considered to be inferior; and the last edition of the catalogue terms them copies. But of works dated 1639 the portrait of Lady Pembroke, in the gallery at Darmstadt, is a really fine specimen; and to the same year belongs a full-length portrait of Arthur Goodwin at Chatsworth. The twin portrait of Thomas Carew and Thomas Killigrew, in the royal collection, dated 1638, is certainly most delicate, but very weak in tone and slight in handling. Van Dyck sailed in September, and probably spent some time with his Antwerp friends. In October he reached Paris, and succeeded in obtaining some important work, when, on 16th November, he was compelled to resign his commissions on account of the state of his health. Scarcely three weeks later (9th December, 1641) he died at his residence at Blackfriars. Van Dyck was buried in old St. Paul's, where a Latin inscription was placed on his tomb by Charles I.

An elegy in Cowley's *Miscellanies* speaks, not only of the painter's talent, but of his amiable disposition. We may perhaps point to the coincidence that a Mrs. Cowley is in Van Dyck's will (of 1st December) named guardian of his child, Justiniana Anna, born only eight days before her father's death. The painter had in the Netherlands an illegitimate daughter, Maria Theresa, who was entrusted to his sister, and to whom he bequeathed £4000 ($19,440). The name of her mother is not known. Not long after her husband's death Lady Van Dyck became the second wife of Sir Richard Pryse of Gogerddan in Cardiganshire. She was dead in 1645. Justiniana Van Dyck, who was married when scarcely twelve years old to Sir John Stepney of Prendergast, was also something of an artist: she painted a Crucifixion, with four angels receiving Christ's blood in chalices. A similar subject had been painted by Van Dyck, as Bellori tells us, for the duke of Northumberland. After the Restoration a pension of £200 ($972) for life was granted to Justiniana Van Dyck, who died before 1690.

Van Dyck is one of the most brilliant figures in the history of art. That he should, in the same subjects chosen by Rubens, have attained the same degree of expression was scarcely possible. Rubens was exceptional precisely through the sweep and power of his imagination; but Van Dyck, applying the same principles to portrait painting, was no less exceptional. Titian, Raphael, Rembrandt, Velazquez, and Frans Hals are not, on the whole, superior to him in this branch. They often delight us with their technical excellence or penetrating study of individuality, but their conception remains entirely different from that of Van Dyck. With him as with Rubens physiognomical interpretation is so intimately connected with picturesque necessity that his portraits scarcely ever fail to leave an indelible impression on the mind. Burnet observes that with Van Dyck the union of the figure and the background seems to have been a principle, not only in respect of light and shade, but also of color. Thus the shapes of his lights are extended or doubled by means of a curtain in the background, etc. Hence Van Dyck, quite unlike the Dutch, is not what may be termed an intimate portraitist. In his eyes a prince, a warrior, a statesman, an artist belong to the world and to posterity, and in the realization of this idea he attains a degree of excellence seldom if ever attained before him. His works may be found lacking in solidity or displaying an unnecessary amount of motion in attitude, but these defects are easily compensated by a sense of proportion, an elegance in outline, a variety of conception united in his best works to the most able technic.

Properly speaking Van Dyck cannot be said to have formed a school. He was followed to London by some of his earlier collaborators, and there soon met a considerable number of others. Jan van Reyn, David Beek, Adrian Hannemann, Mathew Merian, John Bockhorst (Lang Jan), Remy van Leemput, and Peter Thys were foremost among foreigners, Henry Stone and William Dobson among Englishmen. To their assistance the master owed much; but they are also responsible for the vast number of constantly-recurring copies which go by his name. It often requires a very discriminating eye to distinguish some of these copies from the original paintings. Nevertheless after Van Dyck's death many of his coadjutors produced works of undeniable merit. No school more strikingly reflects the influence of Van Dyck than the British school. Stone and Dobson were, properly speaking, the most fortunate of his continuators; and there is little doubt that such masters as Reynolds, Gainsborough, Lawrence, and Raeburn owe a large measure of their superiority to their study of his works.

Though Van Dyck's reputation greatly suffered through the numerous copies he allowed his pupils to take from his works, the case is otherwise with engraving: Vorsterman, Pontius, Peter de Jode, P. Balliu, and S. Bolswert were seldom more fortunate than when under his guidance. De Jode's St. Augustine, Bolswert's Ecce Homo and Crucifixion, Vosterman's Deposition, and especially Pontius's Herman Joseph rank among the masterpieces of the art of engraving. Van Dyck was himself an incomparable etcher, and with the needle arrived at a degree of excellence scarcely inferior to that exhibited in his paintings. Such prints as the portraits of Vorsterman, John de Wael, Snyders, Josse de Momper, Adam van Noort, and above all his own effigy, bear witness to his prodigious knowledge of design. Print collectors pay extravagant prices for a first proof taken from the plates engraved by Van Dyck himself. Mr. Sackville Bale's copy of the portrait of Wawerius fetched £600 ($2916). Van Dyck also employed some of the best engravers of his time for the production of a gallery of illustrious heads, men and women, of different countries. Whether all were taken from life is questionable. Gustavus Adolphus and Wallenstein he can hardly have met. Du Breucq, the architect, he never knew. But all the sketches and drawings were done by himself, and are often met with in public and private galleries. The engravings are sometimes very beautiful and in their first states very rare. Published successively by Martin van der Enden, Giles Hendrickx, and John Meyssens, the collection originally consisted of sixteen warriors and statesmen, twelve scholars, and fifty-two artists. Hendrickx raised the number to ninety-nine, and used as a frontispiece the portrait of Van Dyck, with the following inscription: *Icones principum, virorum doctorum, etc., etc., numero centum ab Antonio Van Dyck pictore ad vivum expressæ eiusq. sumtibus æri incisæ*, 1645. Seventeen editions were published, the last in 1759, with 124 plates. Many of the plates are now the property of the French Government, and belong to the Chalcographie Nationale in Paris.

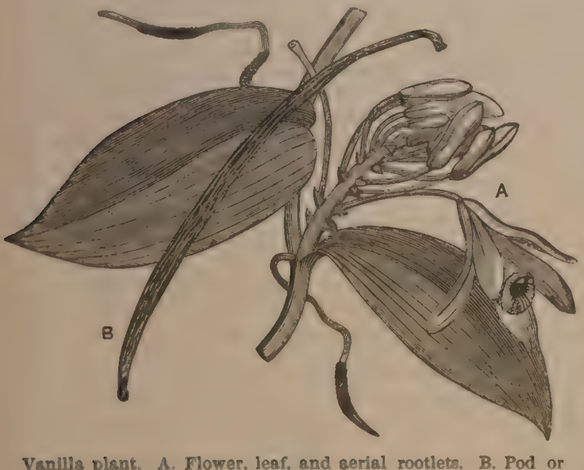
VANE, Sir Henry (1612–1662), the younger, was the son of Sir Henry Vane and Frances Darcy. His father, of an ancient family in Durham, was secretary of state and comptroller of the household under Charles I. Henry was born in 1612 at Hadlow in Kent; and after an education at Westminster, where he was noted for his high and reckless spirits, and at Magdalen, Oxford, where he neither matriculated nor took his degree, he was sent to France and Geneva. Here he no doubt acquired the strongly Puritan views for which he had been prepared by a remarkable change of mind when quite a boy. In spite of the personal efforts of Laud, who made the attempt at the king's request, he refused to give them up, and fell especially under the influence of Pym. In 1635 he emigrated to Massachusetts, where he was elected governor in 1636, though only twenty-four years of age. After two years of office, during which he showed striking administrative ability, he was defeated by Winthrop, the former governor, chiefly on account of the protection he had given to Mrs. Hutchinson in the religious controversies which she raised.

Vane returned to England in August, 1637. Being elected to the Short Parliament for Kingston-upon-Hull, he speedily became a leader of the Independents and a marked man. In order to secure him for the court he was made joint-treasurer of the navy with Sir W. Russell, and was knighted. In November, 1640, he was again elected for Hull to the Long Parliament. Accidentally finding among his father's papers some notes of Strafford's advice to the king after the dissolution of the Short Parliamant, in which Strafford justified the use of force, he handed them to Pym, and on 10th April, 1641, was examined upon them by the House; this disclosure was largely instrumental in bringing about Strafford's downfall. He carried up the impeachment of Laud from the Commons, was a strong supporter, when on the committee of religion, of the "Root and Branch" bill, and in June, 1641, put forward a scheme of church government by which commissioners, half lay and half cleric, were to assume ecclesiastical jurisdiction in each diocese. He was, in fact, foremost in all the doings of the Long Parliament. When war broke out he surrendered his office of treasurer of the navy, but was replaced in it by the Parliament. Hereupon he gave a rare example of disinterestedness by relinquishing all the profits of the office, stated at £30,000 [$145,800] a year, stipulating only that £1000 [$4860] should be paid to a deputy. In August, 1642, he was on the committee of defence. In 1643 he was the leading man among the commissioners sent to treat for a league with the Scots. Vane, who was bitterly opposed to the tyranny of the Presbyterian system, was successful in two important points. The aim of the Scots was chiefly the propagation of their discipline in England and Wales, and for this they wanted only a "covenant." The English desired a political "league." Vane succeeded in getting the bond termed the Solemn League and Covenant, and further in substituting the expression "*according to the word of God* and the example of the best Reformed churches" for the latter phrase alone. In the Westminster Assembly, too, he joined Cromwell in insisting upon full religious liberty, and in opposing the view that the taking of the Covenant should be necessary for ordination. In 1644 he was charged by Essex with holding communication with the court, but explained that he had done so in order to acquire information of the Royalist plans, and was fully acquitted by the House of Lords. He was on the committee of two kingdoms, and was engaged in the negotiations with Charles at Uxbridge in 1645. He was, with Cromwell, a prime mover in the Self-Denying Ordinance and the New Model, and it was he who suggested the filling up of the vacant seats in parliament. His views of government at this time and throughout his life may be best studied in an important paper, the *People's Case Stated,* written shortly before his death. "The power which is directive, and states and ascertains the morality of the rule of obedience, is in the hand of God; but the original, from whence all just power arises, which is magistratical and coercitive, is from the will or free gift of the people, who may either keep the power in themselves or give up their subjection and will in the hand of another." The king, then, having transgressed the condition, and having been conquered, the people were free to change their form of government and, if they pleased, resort to a republic. In 1646 Vane was one of the English commissioners for the preservation of peace with Scotland, and in 1648 was appointed with others to negotiate with Charles at the Isle of Wight. Radical as were his views, he refused all participation in Pride's "purge"—the point where he first broke with Cromwell—and remained in privacy at Raby Castle in Durham until after the king's death, a measure in which he took no part. In 1649, however, he returned to London and was placed on the council of state, though he refused to take the oath which expressed approbation of the king's execution. He was chairman of the committee appointed to consider the mode of election of future parliaments, and his proposals were brought forward in January, 1650. He acknowledged the Commonwealth only so far as he found it "consonant to the principles which have given rise to the law and the monarchy itself in England," and he recognized in a parliament, conforming in other respects to the ancient laws, the supreme authority of the state, whether there were a king at the head of it or not. He wished to reform the franchise on the property basis, to disfranchise some of the existing boroughs, and to give increased representation to the large towns; the sitting members, however, were to retain their seats. In this he was opposed by Cromwell, who desired an entirely new parliament and the supremacy of the army representation; and Vane stands henceforward as the champion of the doctrine of pure parliamentary government. His most useful qualities were exhibited, however, when in March, 1653, he became the head of the commission for managing the army and navy. It was by his exertions in organization that Blake was fitted out with the fleet with which Van Tromp was defeated and the supremacy of England at sea assured. It was at this time that Milton's sonnet was addressed to him. On 20th April Cromwell forcibly dissolved the Long Parliament, when Vane especially received from the Protector studied insult. He was, however, almost at once invited to rejoin the Government. "He answered the invitation by a letter extracted from the Apocalypse wherein the reign of the saints is mentioned, which faith he believes will now begin." In his retirement at Raby he now wrote the *Retired Man's Meditations.* In 1656 he proposed in *A Healing Question* a new form of government, insisting as before upon a Puritan parliament supreme over the army. This he sent to Cromwell, and so alarmed was the Protector at the interest it excited that Vane was summoned on 12th August to the council in consequence. Refusing to give security not to disturb the public peace, he was on 9th September sent prisoner to Carisbrooke Castle, and there remained until 31st December. He had previously, according to his opponents, excited the jealousy of the Government by "going up and down among the Quakers, and endeavoring to withdraw them from their submission to the Government." After the death of Cromwell he stood for Kingston and Bristol successively, and was elected, but the court managers gave the certificate of election to the defeated candidates; finally, however, he was chosen for Whitchurch and took his seat on 27th January, 1659, at the head of the small body of forty republicans. He was at once urgent in pressing that, before Richard Cromwell, for whom he had a great contempt, was acknowledged protector, the limitations of his power, and the full security of parliament and subjects should be settled. Upon Richard's abdication he joined the army leaders in reviving the Rump; and, when the breach occurred between it and the army, he adhered to the latter, accepting a commission from them. He was one of the committee of safety and also of the council of state appointed in May; he was, too, chairman of the army and navy commission, and soon afterwards of another special commission for the navy. In September he was made president of the council. He had, moreover, in May, been appointed with Lambert and others to treat with the Dutch ambassador for freeing the commerce of the Baltic. When Monk arrived in London Vane was ordered to his seat in Lincolnshire, having been discharged from the parliament for espousing the cause of the army.

At the Restoration Vane was imprisoned in the Tower by the king's order. After several conferences between the Houses of Parliament it was agreed that he should be excepted from the indemnity bill, but that a petition should be sent to Charles asking that his life might be spared. The petition was granted. During the conferences he had been moved from prison to prison, and was finally placed in a castle in the Scilly Isles. In his captivity he wrote the *People's Case Stated,* with many other political and religious works of the highest eloquence and beauty. On 7th March, 1662, the Convention Parliament being no longer in existence, he was taken to London, and on 2d June put upon his trial, which was conducted with a shameless absence of equity. He was refused the assistance of counsel and was not allowed to see the indictment before it was read. In his own behalf he spoke courageously and well, pleading the authority of the Long Parliament for his acts, and maintaining that the House of Commons, "representing the whole body of the people in case of a difference between the authority, royal and politic, possessed a just power to defend the right of the people, and to authorize the people of England and every one of them to defend them." Charles, however, was determined that he should die, and, in spite of his answer to the petition mentioned above, wrote himself to Clarendon declaring that Vane was "too dangerous a man to let live, if we can honestly put him out of the way." He was therefore sentenced on 11th June to death. On the 14th he was taken out to execution, and died with the serenity and courage which had marked his life. (O. A.)

VANILLA, a flavoring agent largely used in the manufacture of chocolate, in confectionery, and in perfumery. It consists of the fermented and dried pods of several species of orchids belonging to the genus *Vanilla*.[1] The great bulk of the commercial article is the produce of *V. planifolia*, Andrews, a native of eastern Mexico, but now largely cultivated in several tropical countries, especially in Réunion, the Seychelles, and Java. The plant has a long, fleshy stem and attaches itself by its aerial rootlets to trees, and appears to be little dependent on the soil for nourishment. The leaves are alternate, oval-lanceolate, and fleshy; and the greenish white flowers form axillary spikes. The fruit is a pod from 6 to 12 inches long, and when mature about half an inch in diameter. The wild plant yields a smaller and less aromatic fruit, distinguished in Mexico as *Baynilla cimarona*, the cultivated vanilla being known as *B. corriente*. Mexican vanilla is regarded as the best. It is principally consumed in the United States, which import about 100,000 ℔ of it annually. Réunion produces about the same quantity, which is sent to Bordeaux, the chief centre of the trade in France. Its odor is said to differ from the Mexican variety in having a suggestion of tonqua bean. Guadaloupe produces about 5000 ℔ per annum, which is likewise shipped to Bordeaux. Mauritius exported 20,481 ℔ in 1877. The Seychelles have lately produced large quantities of exceedingly fine quality; the produce of these islands goes chiefly to the London market. The Java vanilla, grown chiefly in Krawang and the Preanger Regencies, is shipped to Holland. The amount exported from the East Indian Archipelago to Holland in 1876 amounted to about 5000 ℔. The best varieties of vanilla pods are of a dark chocolate brown or nearly black color, and are covered with a crystalline efflorescence technically known as *givre*, the presence of which is taken as a criterion of quality. The peculiar fragrance of vanilla is due to vanillin, $C_8H_8O_3$, which forms this efflorescence. Chemically speaking, it is the aldehyde of methyl-protocatechuic acid. It is not naturally present in the fleshy exterior of the pod, but is secreted by hair-like papillæ lining its three internal angles, and ultimately becomes diffused through the viscid oily liquid surrounding the seeds. The amount of vanillin varies according to the kind: Mexican vanilla yields 1.69, Bourbon or Réunion 1.9 to 2.48, and Java 2.75 per cent. Besides vanillin, the pods contain vanillic acid (which is odorless), about 11 per cent. of fixed oil, 2.3 per cent. of soft resin, sugar, gum, and oxalate of lime.



Vanilla plant. A. Flower, leaf, and aerial rootlets. B. Pod or fruit.

Vanillin forms crystalline needles, fusible at 81° C., and soluble in alcohol and ether, hardly soluble in cold, but more so in boiling water. Like other aldehydes, it forms a compound with the alkaline bisulphites, and can by this means be extracted from bodies containing it. Vanillin has been found in Siam benzoin and in raw sugar, and has been prepared artificially from coniferin, a substance found in the sapwood of fir-trees, from asafœtida, and from a constituent of oil of cloves named eugenol. It is from the last named that vanillin is now prepared on a commercial scale, chiefly in Germany. Vanillin does not appear to have any physiological action on human beings when taken in small doses, as much as 10 to 15 grains having been administered without noxious results. On small animals, however, such as frogs, it appears to act as a convulsive. It has been suggested as a stimulant of an excito-motor character in atonic dyspepsia. The poisonous effects that have on several occasions followed from eating ices flavored with vanilla are not to be attributed to the vanilla, but probably to the presence of *tyrotoxicon* (*Pharm. Journ*, [3], xvii. p. 150), a poison found in milk which has undergone certain putrefactive changes, and producing choleraic effects, or perhaps to the presence of microscopic fungi in the vanilla, the plantations being liable to the attack of *Bacterium putredinis*. Workmen handling the beans in the Bordeaux factories are subject to itching of the hands and face; but this is caused by an *Acarus* which occupies the end of the pod. In some cases, however, symptoms of dizziness, weariness, and malaise, with muscular pains, have been felt, due probably to the absorption of the oily juice by the hands of the workmen. These symptoms have been attributed to the variety of vanilla known as vanillon, but it seems equally probable that they are due to idiosyncrasy.

The method of cultivation and preparation of vanilla for the market varies somewhat in different countries. In Mexico a clearing is made in the forest, where a few young trees, 12 or 15 feet apart, are left to serve as a support for the climbing stems of the vanilla plant. Close to each tree two cuttings, 3 to 5 feet in length, are inserted in the soil to the depth of about a foot, the upper part being tied to the tree. The cuttings become rooted in about a month, but do not bear fruit until the third year. They continue to bear for about thirty years. In Réunion, Mauritius and the Seychelles the young plants are supported by a rude trellis made between the trunks of trees. Although the plants are probably fertilized by insects in their native country, in Réunion and elsewhere fertilization has to be promoted by hand. Only the finest flowers of each spike are fertilized, or the plants would die of exhaustion. The pods are cut off separately as they ripen, since, if over-ripe, they are apt to split in drying, and if unripe the product will be of inferior color and fragrance. The pods take a month to arrive at full size and six months longer to ripen. The exact time for collecting is judged by the crackling of the pod when pinched between the fingers. The aroma of vanilla is developed by fermentation, and is said not to pre-exist in the ripe fruit.

In Mexico the pods, after they are gathered, are placed in heaps under a shed until they begin to shrivel, and are then submitted to a sweating process. They are next wrapped in a woollen cloth and exposed to the sun during the day, or heated in an oven to 140° Fahr. if the weather is cloudy, and then inclosed in air-tight boxes at night to sweat. In twenty-four to thirty-six hours, according to size, the pods have acquired a fine chestnut-brown color.

---

[1] Span. *vainilla*, dim. of *vaina*, a pod.

They are then spread in the sun for about two months to dry, and are subsequently tied up into small packets of uniform length. In Réunion the pods are sorted into lengths and scalded in boiling water, the long pods being immersed ten seconds, those of a medium size fifteen seconds, and the short ones for fully one minute. They are next exposed to the sun between woollen blankets for about a week, until they assume the characteristic brown color. They are then spread out under zinc-roofed sheds and turned frequently to insure equal drying. When the beans can be twisted round the finger without cracking, the "smoothing process" is commenced. This consists in passing the beans between the fingers frequently, apparently to distribute equally the unctuous liquid which exudes as the fermentation proceeds, and to which the lustre and suppleness of the bean are due. When dry they are tied up in bundles of uniform length. These are divided into three commercial sorts: (1) those which are nearly black and glossy and which soon become frosted; (2) those which are lighter in color, more or less spotted with gray, and not so glossy; (3) those which are gathered in an unripe condition and become little, if at all, frosted over with crystals. In Guiana, where an inferior quality is prepared, the beans are placed on ashes and left until they begin to shrivel; they are then wiped, rubbed over with oil, and, the lower end of the pod having been tied, are hung up in the air to dry.

Other Varieties.—In Brazil, Peru and other parts of South America a broad and fleshy vanilla is prepared, which has an inferior odor. It is believed to be obtained from *V. pompona*, Schiede, which has been found to contain, besides from .4 to .7 per cent. of vanillin, another ingredient, benzaldehyde, by which the odor of vanilla is modified. This variety is often distinguished as vanillon in commerce. It is destitute of *givre*. Rio vanilla is collected on the banks of the Parahyba river in the province of Rio de Janeiro, Brazil, and is obtained from *V. palmarum*, Lindl. It has been found to yield 1.03 per cent. of vanillin. It is of inferior quality, but might be improved if more attention were paid to the curing process. Guiana vanilla is a coarse variety obtained from *V. guianensis*, Splitberger. The pods are short, thick and frequently split open, and of inferior fragrance. None of the South-American vanillas appear to be used in Great Britain for flavoring purposes, but solely for perfumery. (E. M. H.)

VANINI, LUCILIO (1585–1619), philosopher, was born at Taurisano, near Naples, in 1585. He studied philosophy and theology at Rome, and after his return to Naples applied himself to the physical studies which had come into vogue with the Renaissance. Though unmethodically cultivated and destitute of definite results, physical science powerfully affected men's imaginations in this transition period between the break-up of scholasticism and the rise of modern thought, and exercised an important influence upon philosophy. Giordano Bruno is perhaps the most striking instance of this, and Vanini in some respects resembles Bruno, though much his inferior both intellectually and morally. Both represent the spirit of revolt against the old, the ferment and unrest of the 16th century. Vanini resembles Bruno, not only in his wandering life, but also in his anti-Christian bias, and in the tragic death which he suffered at the hands of the constituted authorities. From Naples Vanini proceeded to Padua, where he came under the influence of Pomponatius, whom he styles his divine master. Pomponatius belonged to the Alexandris school of Aristotelians, and denied the immortality of the soul. Vanini speaks of Aristotle as "the God of philosophers, the dictator of human nature, and the sovereign pontiff of the sages," but gives the same naturalistic turn to the Aristotelian doctrine. At Padua, where he appears to have remained for several years, Vanini added law to his other acquirements, and he is at pains to print himself in his books as *doctor utriusque juris.* He was also ordained priest; but, on leaving Padua, he led a roving life in France, Switzerland and the Low Countries, supporting himself by giving lessons and using the opportunity, it would seem, for the dissemination of anti-religious views. He was obliged to flee from Lyons to England in 1614, but was imprisoned in London for some reason for forty-nine days. Being set at liberty, he returned to Italy and made an attempt to teach in Genoa, but the same complaints being made against him drove him once more to France. Here he made a valiant effort to clear himself of suspicion by publishing a book against atheists,—*Amphitheatrum Æternæ Providentiæ Divino-Magicum, necnon Astrologo-Catholicum, adversus Veteres Philosophos, Atheos, Epicureos, Peripateticos, et Stoicos* (1615). It has been said that by the weakness of his answers, he designedly gives his opponents the victory under pretence of refuting them; but, though the definitions of God are somewhat pantheistic, the book is sufficiently orthodox. Yet it cannot be taken as expounding his own views. Vanini expressly tells us so in his second (and only other published) work, and the tone of that work would be sufficient proof without this assurance. Though certified by two doctors of the Sorbonne, the second book undoubtedly preaches a pantheism nearly akin to atheism, and a sensualistic ethics strongly tinged with immorality. The title (*De Admirandis Naturæ Reginæ Deæque Mortalium Arcanis*) correctly indicates its general tenor. It was published at Paris in 1616, and was soon afterwards re-examined by the Sorbonne and condemned to the flames. This was the occasion of Vanini's leaving Paris, where he had been staying as chaplain to Marshal de Bassompierre, to whom the book is dedicated. He began to teach in Toulouse, but soon roused the clergy and magistrates against him. He was arrested in November, 1618, and after a prolonged trial was condemned, as an atheist, to have his tongue cut out, and to be strangled at the stake, his body to be afterwards burned to ashes. This savage sentence was executed on 9th February, 1619. During his imprisonment, it is said, he professed the most orthodox Catholicism, but as soon as all hope was gone gave vent to his true feelings in ribald impieties. He appears to have met his fate with courage, mingled perhaps with bravado. His moral character was loose and vicious, and his writings show him to have been a man of inordinate vanity. Though he possessed unquestionable gifts, neither originality nor profundity can be claimed for him as a thinker. His fate, however, has given him a species of fame.

The best modern account of Vanini is to be found in Cousin's *Fragments de Philosophie Cartésienne.* His works have been republished by Rousselot.

VANLOO, CHARLES ANDREW (1705–1765), subject painter, a younger brother of John Baptist Vanloo (see below), was born at Nice on 15th February, 1705. He received some instruction from his brother, and like him studied in Rome under Luti. Leaving Italy in 1723, he worked in Paris, where he gained the first prize for historical painting. After again visiting Italy in 1727, he was employed by the king of Sardinia, for whom he painted a series of subjects illustrative of Tasso. In 1734 he settled in Paris, and in 1735 became a member of the French Academy; and he was decorated with the order of St. Michael and appointed principal painter to the king. By his simplicity of style and correctness of design, the result of his study of the great Italian masters, he did much to purify the modern French school; but the contemporary praise that was lavished upon his productions now appears undue and excessive. His Marriage of the Virgin is preserved in the Louvre. He died at Paris on 15th July, 1765.

VANLOO, JOHN BAPTIST (1684–1745), subject and portrait painter, was born at Aix in Provence on 14th January, 1684. He was instructed in art by his father. Having at an early age executed several pictures for the decoration of the church and public buildings at Aix, he was employed on similar work at Toulon, which he was obliged to leave during the siege of 1707. He was patronized by the prince of Carignan, who sent him to Rome, where he studied under Benedetto Luti. Here he was much employed on church pictures, and in particular executed a greatly praised Scourging of Christ for St. Maria in Monticelli. At Turin he painted the duke of Savoy and several members of his court. Then, removing to Paris, where he was elected a member of the French Academy, he executed various altar-pieces and restored the works of Primaticcio at Fontainebleau. In 1737 he came to England, where he attracted attention by his portrait of Colley Cibber and of Owen McSwiny, the theatrical manager; the latter, like many other of Vanloo's works, was engraved in mezzotint by the younger Faber. He also painted Sir Robert Walpole, whose portrait by Vanloo in his robes as chancellor of the exchequer is in the National Portrait Gallery (London), and the Prince and Princess of Wales. He did not, however, practice long in England, for his health failing he retired to Paris in 1742, and afterwards to Aix, where he died on 19th December, 1745. His likenesses were striking and faithful, but seldom flattering, and his heads are forcible in coloring. The draperies and accessories in his pictures were usually painted by Van Achen, Eccardt, and Root.

VANNES (Breton *Gwened*), a town of France, chef-lieu of the department of Morbihan and an episcopal see, is situated on a little stream, 10 miles from the Gulf of Morbihan and 84 northwest of Nantes on the railway to Brest. The narrow, steep, and crooked streets of the old town, which lie on a hill facing the south, are surrounded by fortifications of the 14th, 15th, and 17th centuries, pierced by four gates and flanked by nine towers and five bastions, connected by battlements. Some of the remains are Roman, and in the Constable's Tower Olivier de Clisson was confined in 1387. The modern suburbs, with public buildings, barracks, convents, squares, walks, and the port surround the old town. The archæological museum contains one of the richest collections of prehistoric remains in Europe. There are also a museum of natural history and a library (10,000 volumes). The cathedral of St. Peter overlooks the old town; burnt by the Normans in the 10th century, it was rebuilt in the 13th, 15th, and 18th centuries. It has no architectural interest, but contains the relics and tomb of St. VINCENT FERRER (*q.v.*). The curious round Chappelle du Pardon was built in 1557 in the Italian style. Some interesting old houses, including that of St. Vincent Ferrer and that of the parlement of Brittany, the rich private collections of M. de Limur, the huge barracks, and three large hospitals should also be mentioned. In 1882 thirty-five vessels (3480 tons) entered and seventy-four (7225 tons) left the port of Vannes, which is accessible to vessels of 150 tons; those of 800 tons can come to within 2 miles. The population in 1881 was 16,667 (commune 19,284), and had increased by 1886 to 18,127 (commune 20,036).

Vannes (*Dariorigum*), the capital of the Veneti, was at the head of the Armorican league against Julius Cæsar, who in 56 B.C. overcame their fleet and opened up their country by six roads. St. Paternus, the first bishop, was consecrated in 465. In the 5th century Vannes was ruled for a time by independent counts, but soon came under the yoke of the Franks. Nominoe, the lieutenant of Louis the Pious in Brittany, assumed the title of king in 843, and one of his brothers was the founder of a line of counts who distinguished themselves against the Normans in the 9th and 10th centuries. Vannes became part of the duchy of Brittany under Geoffrey, who died in 1008, and the estates of Brittany met there for the first time after the death of Arthur of Brittany. In the course of the War of Succession the town was besieged four times in 1342. Duke John IV. built here the castle of L'Hermine and made it his habitual residence. In 1487 the town was for a year in the hands of Charles VIII. of France. In 1532 Brittany was definitively united to France. The estates met at Vannes several times in the 17th and 18th centuries. During the Revolution this town was the scene of highly dramatic episodes, including the execution of some of the prisoners of Quiberon.

VANNUCCI. See PERUGINO.

VAPOR. See EVAPORATION.

VAR, a department of France, formed in 1790 of part of Provence, but reduced in 1860 by the formation of the department of Alpes-Maritimes, so that the Var no longer flows through the department to which it gives its name. Situated between 42° 58′ and 43° 55′ N. lat. and 5° 39′ and 6° 57′ E. long., Var is bounded by the Mediterranean on the S., by Alpes-Maritimes on the E., by Basses-Alpes on the N., and by Bouches-du-Rhône on the W. In the N. W. it touches the department of Vaucluse. The river Verdon on the N. and the Siagne on the N.E. are natural boundaries. The surface of the department is one of the most broken in France; the highest point is in the northeast, where a peak of the Alps rises to 5620 feet and is surrounded by others ranging from 4500 to 5000 feet. These calcareous hills are much fissured and very dry on the higher plateaus, but are rich in springs, which occasion a very beautiful verdure in the valleys. Towards the west rises the St. Baume (3700 to 3800 feet), which is connected on the south with the hills above Toulon (2300 feet). The Maures (2550 feet), which extend between the coast from Hyères to Fréjus, and the valley of the Argens form, geologically speaking, a sort of island in Provence, being composed of granite, gneiss, and schists. To the north of the Argens rises the independent Estérel Range (2020 feet), mostly composed of igneous rocks, with some schists and porphyry. The principal river is the Argens (71 miles), which drains the larger portion of the department, traversing it from west to east, and falling into the sea a little south of Fréjus. Its minimum volume is 72,000 cubic feet, even in the driest weather and when most lavishly drawn on for irrigation. Nominally it is navigable for 11 miles, but in point of fact it is used only for floating timber. Draguignan, the chef-lieu of Var, is situated on the Nartuby, the principal tributary of the Argens. Other streams are, in the north the Verdon, a tributary of the Durance, in the west the Huvaune and Arc, in the south the Gapeau, and in the east the Siagne. The coast-line, which is one of the most beautiful and picturesquely varied in France, runs from west to east between the Gulf of La Ciotat and Cape Comarat, then from southwest to northeast between the Gulfs of St. Tropez and La Napoule. The shore is dotted from west to east with the sand-covered remains of the Phocæan city of Tauroentum; the little ports of Bandal and St. Nazaire; the peninsula of Cape Sicié, 1180 feet high, with its projection Cape Cépet (see TOULON); the roads of Toulon; the roads of Giens, the site of the Gallo-Roman town of Pomponiana; the peninsula of Giens, formerly an island attached to the mainland by two long spits of sand, between which lies the lagoon of Les Pesquiers with its "salines"; the great anchorage of Hyères, shut off from the Mediterranean on the south by the hilly and wooded islands of Porquerolles, Port-Cros, and Le Levant; the bold promontories of the Maures Mountains, dividing the coast into lovely bays; Cape Comarat (430 feet), with a lighthouse; the deep Gulf of St. Tropez, with perhaps the best anchorage in all Provence; the Gulf of Fréjus, where owing to the accumulated alluvial deposits of the Argens the site of the Roman port of Forum Julii is now occupied by the inland town of St. Raphael; the porphyry headlands of the Estérel Range, with the roads of Agay between them; and Cape Roux (1486 feet). The climate is remarkably fine and mild on the coast, where there is complete shelter from the north wind, but is more severe in the mountains. Hyères and St. Raphael are favorite invalid resorts. The average temperature is 58° Fahr. at Toulon, 59° at Hyères. The annual rainfall is 19 inches at Toulon and 24 in the valley of the Argens.

Of the total area of 1,489,488 acres 379,021 are arable, 529,660 under wood, 185,333 under vineyards, 14,857 are meadows and orchards, 49,606 pasture, and 142,466 uncultivated. The live stock includes 8460 horses (many of Arab blood), 13,230 mules, 5420 asses, 3015 cattle, 105,840 sheep (wool-clip in 1879, 234 tons 4 cwts., valued at £10,000

[$48,600]), 19,900 pigs, and 14,815 goats. There were 14,380 beehives (42 tons 10 cwts. of honey and 28 tons 7 cwts. of wax in 1879). In 1884 366 tons 15 cwts. of silk cocoons were produced. The crops in 1884 were 1,485,000 bushels of wheat, 13,200 of meslin, 11,000 of rye, 30,250 of barley, 7150 of maize, 2640 of millet, 125,400 of oats, 4,840,000 of potatoes, 2512 tons of beet-root, and 103,000 tons of different kinds of fodder. The vines, reduced by 60 per cent. since 1875 by the phylloxera, yielded in 1884 over 7,000,000 gallons of wine (average of previous 10 years over 29,000,000 gallons). In 1879 olives occupied 77,777 acres and yielded 1,384,856 bushels; four-fifths of the crop was pressed for oil and yielded 5256 tons. Mulberries, strawberries, pears, peaches, plums, figs, almonds, oranges, pomegranates, lemons, jujubes, guavas, and Japanese medlars are grown; and the laurel, palm tree, date tree, eucalyptus, cactus, and sugar cane flourish. An export trade is carried on in flowers, and also in truffles, capers, and onions. The forests are planted with white and evergreen oaks, cork trees, maritime pines, and chestnuts. In the dense, and almost virgin, forest of St. Baume are beeches, maples, limes, oaks, elms, yews, and pines, and the flora of the district is botanically most interesting. Var possesses mines of iron, lead, aluminium, and coal (2846 tons of coal, 2075 tons of lignite in 1885). From 300 to 400 workmen are employed in the production of salt and chemicals. Hyères (population 13,170 in 1886) produces annually from 20,000 to 25,000 tons of salt. Marble, plaster, stone, chalk, clay, sandstone, and sand for glass are quarried or dug. There are 200 manufactories of pottery, earthenware, and tiles. Toulon (57,635), La Seyne (12,186), St. Tropez (3622), and Bandol, where ships are built, are the chief industrial centres. There are silk, woollen (250 spindles, 6 looms), and cotton (350 spindles, 9 looms) mills, hat, cloth, and cork manufactories (1000 workmen), tan yards, paper mills, (670 tons in 1879), printing establishments, tinned food manufactories, soap works (172 tons), breweries, glass works, oil mills—in all 173 establishments. There are tunny, anchovy, and sardine fisheries. The department has 140 miles of railway, 164 of national roads, and 2448 of other roads. About half the population of 288,577 (1881) were agricultural, 46,691 manufacturing, and 30,228 marine. In 1886 the total population of the department numbered 283,689. Var is divided into 3 arrondissements (Draguignan, the chef-lieu, with 8562 inhabitants in 1886; Brignoles, with 4393 inhabitants; and TOULON (*q.v.*), 28 cantons, and 145 communes; it forms the diocese of Fréjus, and belongs to the jurisdiction of the Aix court of appeal and to the district of the Marseilles army corps.

VARASD (Germ. *Warasdin*), a royal free city of Hungary, in the county of Varasd, in Croatia, lies about 40 miles north-northeast of Zágráb (Agram), on the river Drave. It was once used as a stronghold, but now only the castle remains fortified. Varasd possesses several churches of interest, a fine new county hall, two gymnasia, and a real school. It has also tobacco and liqueur factories, and enjoys a brisk trade in wood and fruits, especially plums. The inhabitants numbered 13,701 in 1880.

VARENIUS, BERNHARDUS, or BERNHARD VAREN (1622–1670), geographer, was born at Hitzacker on the Elbe, in the Lüneburg district of Hanover. His early years were spent at Uelzen, where his father was court preacher to the duke of Brunswick. Varenius studied at the gymnasium of Hanover and at Königsburg and Leyden universities, where he devoted himself to medicine, taking his degree in 1649. He then settled at Amsterdam, intending to practice medicine. But the recent discoveries of Tasman, Schouten, and other Dutch navigators, and his friendship for Blauw and other geographers, roused in Varenius an interest in geography, and it was in this study that the principal achievements of his life were gained. He died in 1670.

In 1649 he published, through Elzevir, his *Descriptio Regni Japoniæ*, an excellent compilation, which may still be read with profit. In this was included a translation into Latin of Schouten's account of Siam and chapters on the religions of various peoples. Next year appeared the work by which he is best known, his *Geographia Generalis*, in which he endeavored to lay down the general principles of the subject on a wide scientific basis, according to the knowledge of his day. The work is divided into (1) absolute geography, (2) relative geography, and (3) comparative geography. The first investigates mathematical facts relating to the earth as a whole, its figure, dimensions, motions, their measurement, etc. The second part considers the earth as affected by the sun and stars, climates, seasons, the difference of apparent time at different places, variations in the length of the day, etc. The third part treats briefly of the actual divisions of the surface of the earth, their relative positions, globe and map construction, longitude, navigation, etc. Though the subject as treated by Varenius is crude and ill-defined, still, with the materials at his command, he dealt with it on the whole in a really philosophic and scientific spirit; and it long held its position as the best treatise on scientific geography in existence. The work went through many editions. Sir Isaac Newton introduced several important improvements into the Cambridge edition of 1672; in 1712 Dr. Jurin issued an edition with a valuable appendix; in 1733 the whole work was translated into English by Dugdale; and in 1736 Dugdale's second edition was revised by Shaw. In 1755 a French translation of Shaw's edition appeared in Paris. There was also an Italian edition printed at Naples in 1716.

See a paper on Varenius by H. Blink in *Tijdschr. van het Nederl. Aardrijks. Genootschap*, ser. ii. pt. iii., 1887.

VARIABLE, COMPLEX. 1. The solution of a quadratic equation involves the extraction of the square root of a quantity which may be negative. In that case the solution is of the form $a+\sqrt{-b^2}$ which, may be written $a+b\sqrt{-1}$, or $a+ib$, putting, with Gauss, for brevity, $\sqrt{-1}=i$. Analysis was, therefore, at a very early stage compelled to contemplate the possibility that symbols of magnitude may represent combinations of dissimilar constituents; but it is only within the 19th century, mainly owing to the initiative of Cauchy and of Gauss, that the whole domain of analysis has been explored from this point of view. A quantity, $a+ib$, consisting of a real part containing a units and an imaginary part containing b units, was called by Gauss a complex number, and the conception of it includes those of each kind, the real and the purely imaginary as they are found from it by making in succession $b=0$ and $a=0$. Quantities thus expressed are subject to all the ordinary algebraic rules applicable to real quantities, and in addition to the relation $i^2=-1$. The occurrence of this symbol i in an identity thus singles out two distinct identities; for instance, if the product of $a+ib$ and $a'+ib'$ be $A+iB$, we have $A=aa'-bb'$ and $B=ab'+ba'$; and in this sense Cauchy, as lately as 1844, still maintained that every imaginary equation was only the symbolic representation of two equations between real quantities. If either or both of the real quantities be variable, the quantity is called a complex variable; adopting the usual notation, it is then written $x+iy=z$. In order that z may vanish, both x and y must do so, as it is not possible for the real part to cancel the imaginary. But either part becoming infinite renders z infinite, and a breach of continuity in the change of the variable z arises when either x or y is discontinuous; but, as long as both change continuously, z is also a continuous complex variable.

2. As long as a variable is conceived to admit of real values only, the distances from a fixed point, measured along a right line, are sufficient to represent it. These may be taken positively or negatively, and in both directions, through all magnitudes, from a vanishing amount to values large beyond conception, *i.e.*, infinite. But, inasmuch as a complex variable $z=x+iy$ depends on two perfectly independent real variables, x and y, its geometrical realization demands a field of two dimensions. When this is assumed to be a plane, to each value $z=x+iy$ corresponds a point P of the plane whose rectangular co-ordinates referred to an arbitrarily assumed pair of axes in the plane have the real values x and y. Thus to all real quantities in the old sense correspond the points of the axis of abscissæ and to pure imaginaries those of the axis of ordinates. The co-ordinates of the point P may change quite independently, just as the variables x and y do. If the point P be given, the corresponding value of z is known, and

also for a given value of z the corresponding point P is known. The continuous variation of z is exhibited by the motion of P on a curve. The complex number may also be written in the following form, which is found as early as Euler. Joining the point P to the origin O, the line $OP=\rho$ is called the *modulus*, and the angle $XOP=\theta$ which this line forms with the positive axis of x, or the prime axis, is called the *argument* (or *amplitude*) of the complex $x+iy$. Thus $\rho=+\sqrt{x^2+y^2}$, $\cos\theta=x/\rho$, $\sin\theta=y/\rho$, and $z=x+iy=\rho(\cos\theta+i\sin\theta)=\rho e^{i\theta}$. This, again, shows that the variable vanishes only when $x=0$ and $y=0$, *i.e.*, when $\rho=0$, since no real angle makes $\cos\theta+i\sin\theta=0$. In this way the quantity is represented by rotating through the angle θ from the prime axis a line whose length is ρ. The value of the radical $\sqrt{x^2+y^2}$ is always taken positively; the difference of sign arises from a reversal of direction and is indicated by the angle in the factor $e^{i\theta}$. When P is given, ρ is unique and θ is determined by $\cos\theta$ and $\sin\theta$: that is to say, it admits only of a certain value or of those which differ from it by integer multiples of 2π. Thus two quantities are equal whose moduli are equal and their directions parallel. The modulus varies continuously with z, and so does the argument, except when z vanishes: that is, when the curve passes through the origin, the argument then undergoes generally a sudden change by π.

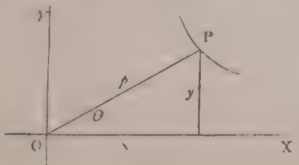


FIG. 1.

3. Complex numbers form a system complete in themselves, and any process of calculation on complex numbers always reproduces a complex number. Thus, as any such quantity is represented by a point approached from a given point, the result of calculation also has a point or points to represent it. This is illustrated as follows.

The addition of the quantity $z=x+iy$ to $z'=x'+iy'$ produces $z_1=x+x'+i(y+y')$; the point z_1 has the coordinates $x+x'$, $y+y'$: that is, it is the extremity of the diagonal of the parallelogram included by the lines Oz and Oz'. If a third quantity $z''=x''+iy''$ were added on, the result would be represented by the diagonal of the parallelogram included by Oz_1 and Oz''; and so on. Subtraction is the addition of a line with opposite sign. The modulus of the sum or difference of two quantities is found by assuming $\rho_1\cos\theta_1=\rho\cos\theta\pm\rho'\cos\theta'$ and $\rho_1\sin\theta_1=\rho\sin\theta\pm\rho'\sin\theta'$, whence $\rho_1^2=\rho^2+\rho'^2\pm2\rho\rho'\cos(\theta-\theta')$. Thus the modulus of the sum is never greater than the sum of the moduli and the modulus of the difference never less than their difference. The line zz_1 in Fig. 2 is found by subtracting z from z_1, and is thus seen to be equal to the parallel line Oz'. The multiplication of $z=\rho e^{i\theta}$ by $z'=\rho' e^{i\theta'}$ gives $Z=zz'=\rho\rho' e^{i(\theta+\theta')}$: that is, we have to measure along a line inclined to the prime axis at an angle equal to the sum of the arguments a length representing the product of the moduli; in order to determine this, the unit of length must be introduced. If this be OU measured along the prime axis, Z is constructed by placing on Oz' a triangle $z'OZ$ similar and similarly placed to UOz. From this we can proceed at once to division; as an example, when $\frac{z''_1-z'_1}{z'_1-z_1}=\frac{z''-z'}{z'-z}$, the triangle formed by the three points representing z_1, z'_1, z''_1 is homothetic with that formed by z, z', z''.

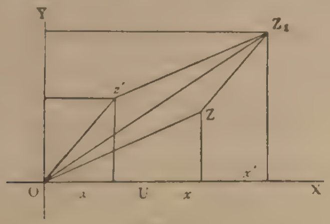

FIG. 2.

In like manner we might proceed to powers of complex quantities with real exponents: *e.g.*, every complex number has n distinct nth roots included in the form $\sqrt[n]{z}=\sqrt[n]{\rho}\,.\,e^{i(\theta+2k\pi)/n}$; then to powers with complex exponents; to logarithms of complex numbers: for example, every number has infinitely many logarithms to the base e, which differ by multiples of $2i\pi$, in accordance with the formula $\log z=\log\rho+i(\theta\pm2k\pi)$; and, finally, to powers with complex base and complex exponent. All these in turn lead again to complex numbers, and to such only.

4. In dealing with real numbers any definite range of values is represented by the points of a finite right line; but to realize a definite range of complex numbers we must have recourse in general to a "region" of two dimensions of the plane bounded by some curve. For instance, all complex numbers whose modulus is less than ρ and greater than ρ' occupy a region bounded by two concentric circles with radii ρ and ρ' round the origin. All those whose moduli are equal to ρ form a linear region, namely, the circumference of the circle round the origin with that radius. A region of two dimensions is called *connected* when we can pass from any point within it to any other point within it without crossing the boundary curve. A quantity is said to be *unrestrictedly variable* in a region when it can assume all numerical values in this region. It is said to be *continuously variable* when all values which it assumes always belong to a finite connected region. Thus a variable is said to be unrestrictedly continuous for a certain value when it can take all the values which belong to a finite region, however small, which includes this value. The variable is restrictedly continuous for this value when the values it takes near this one form a region on whose boundary the value itself occurs, or it may be a region of one dimension. It is discontinuous for this value when the point is isolated, and does not belong to any region. When we know two definite values of a real variable, we know all the intermediate values which it must assume in passing from one to the other; but in the case of the complex variable there is an essential difference: it can pass continuously from one given value to another by infinitely numerous series of continuously consecutive values. In geometric terms, with the real variable we can only travel along the axis of x, with the complex we can travel along any path whatever leading from one point to the other.

5. When the values of one complex variable $w=u+iv$ are determined by the values of another $z=x+iy$, in such a way that for each value of z within a definite region one or more values can be assigned to w by performing a definite set of mathematical operations on z, then w is said to be a function of the complex variable z. Functions are distinguished as *one-valued* and *many-valued* according to the number of values of w which belong to one value of z, as *algebraic* and *transcendental* according to the form in which the variables appear, and as *implicit* and *explicit* according as the relation is solved for w or not. The course of the function w will accordingly be illustrated by points in another plane or planes having the rectangular co-ordinates u and v, and its dependence on z will be geometrically a transformation from one plane to the other. A very simple instance is when $w=1/z$, where the transformation is equivalent to geometric inversion. If the explicit function $w=f(z)$ is to be unrestrictedly continuous in the region for which it has definite values, there must be a finite connected area, however small, around any admissible value of z, to which corresponds a connected region of w: that is, u and v must vary continuously when x and y do so. Let z be

increased by $\triangle z=\triangle x+i\triangle y$ and put $w+\triangle w=(u+\triangle u)+i(v+\triangle v)=f(z+\triangle z)$; then in whatever way $\triangle x$ and $\triangle y$ may converge to zero we must have $\lim\triangle u=0$ and $\lim\triangle v=0$: in other words, w is continuous for a value z, when this value can be included in a region such that for every value $z\times\triangle z$ within it, the modulus of the difference $\mathrm{mod}(\triangle w)=\mathrm{mod}[f(z+\triangle z)-f(z)]=\sqrt{\triangle u^2+\triangle v^2}$ is less than any assignable small number.

6. We proceed to give some elementary examples of functions.

Ex. 1. *The power with positive integer exponent.* $w=z^m$ is a one-valued (*monotrope*) function which is continuous for the entire plane, since $u=\rho^m\cos m\theta$, $v=\rho^m\sin m\theta$ are continuous functions of ρ and θ which do not alter when the argument θ is increased by multiples of 2π. When z becomes infinite so does w, and thus this value z is a *singular* one (*pole*) for the function, as contrasted with a *regular* one, which is such that a function has a finite value continuously changing with z.

Ex. 2. *Any rational integer function of the nth degree in z.* $f(z)=a_0+a_1z+a_2z^2+\ldots+a_nz^n$ is one-valued and continuous for the entire plane and has no singularity, except for $z=\infty$, for which it becomes infinite (pole).

Ex. 3. *The power with a rational fractional index.*

$$w=z^{p/q}=\rho^{p/q}\left(\cos\frac{p}{q}(\theta+2k\pi)+i\sin\frac{p}{q}(\theta+2k\pi)\right),$$

where k takes all integer values from 0 to $q-1$. Each value of k determines at each spot the value of a *branch* of the function, which is therefore a many-valued (*polytrope*) one. At the points $z=0$ and $z=\infty$ all branches have the same value. Thus, if $p/q>0$, at $z=0$ the value of w is 0; at $z=\infty$ its value is ∞. These two points are called *branch* (*critical*) *points* of the function. If we wish to contemplate the values of the function which belong to one branch, so as to have each branch by itself in general a continuous function, we employ the method of Cauchy: that is, we draw from the origin to the point infinity a curve which does not enclose any space, for instance, the positive part of the axis of x. Suppose we let $p=1$, $q=2$, then $w=\rho^{\frac{1}{2}}e^{\frac{1}{2}(\theta+2k\pi)i}$, where $k=0$ or 1. Taking $k=0$, the values of the independent variable and of the function along the prime axis for $\theta=0$ are $z=\rho$ and $w=\rho^{\frac{1}{2}}$; along the axis of y when $\theta=\pi/2$ they are $z=\rho i$ and $w=\rho^{\frac{1}{2}}e^{\frac{1}{4}\pi i}$; along the negative axis of x when $\theta=\pi$ they are $z=-\rho$ and $w=\rho^{\frac{1}{2}}e^{\frac{1}{2}\pi i}$; along the negative axis of y, when $\theta=3\pi/2$, $z=-\rho i$ and $w=\rho^{\frac{1}{2}}e^{\frac{3}{4}\pi i}$; and along the prime axis, on completing a rotation, when $\theta=2\pi$, $z=\rho$ and $w=-\rho^{\frac{1}{2}}$. Hence, for any value of ρ, w is continuous all round the circle, but its ultimate value is different from its initial value.

Thus, as will happen in general with many-valued functions along their branching sections, the values belonging to points alongside of the prime axis having positive ordinates, however small, differ by finite amounts from those for the corresponding points, however near that line, having negative ordinates. The branch of the function so constructed is therefore discontinuous along the prime axis. Accordingly we conceive the plane cut through along this prime axis, and the branch of the function is easily seen to be continuous in the connected surface, which consists of the infinite plane so cut through. Riemann perfected this method of Cauchy and enabled us to keep all the branches simultaneously in view, and thus regard the function as unique and continuous upon all admissible paths without restriction. His process is in the case of a q-valued function to let the variable z move upon q different plane leaves.

Thus, as above, when $p=1$, $q=2$, taking the case $k=1$, let us suppose z to move in a second plane; proceeding as before for the points of the prime axis, we have now $\theta=0$, $z=\rho$, $w=\rho^{\frac{1}{2}}e^{\pi i}=-\rho^{\frac{1}{2}}$; and, when $\theta=2\pi$, $z=\rho$ and $w=\rho^{\frac{1}{2}}e^{2\pi i}=\rho^{\frac{1}{2}}$. Thus, though the rotation has brought w round continuously from the values for small positive ordinates to those for small negative ones, these last differ finitely from the first. Now these final values in the second plane are the same as the initial ones in the first plane; moreover, the final values in the first leaf are the same as the initial ones in the second; hence, if the second leaf be cut through all along the prime axis, as the first was, and if we conceive the leaves to cross one another (as indicated in profile in Fig. 3) all along the cut, we have a connected two-leaved surface, called by Riemann a *winding surface of the first order*, to each point of which corresponds a definite value of the function $w=z^{\frac{1}{2}}$, and to each continuous curve in it, whether in the same leaf or passing through both, correspond values of the function which vary continuously; every closed curve which crosses the branching section either an even number of times or not at all leads finally back to the initial value. This conception can evidently be extended to surfaces with a greater number of leaves corresponding to functions admitting of a greater number of values.

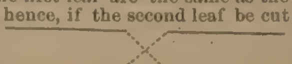

Fig. 8.

7. In considering infinite series we must explain the conception of absolute convergence introduced by Cauchy: an infinite series of real quantities is *absolutely convergent* when the sum of its positive terms taken apart, and likewise that of its negative terms taken by themselves, are each finite. When these are not separately finite, a series which converges for some value of the variable is *semi-convergent.* A complex series $\Sigma(u+iv)$ converges absolutely when the u series and the v series are both absolutely convergent. Hence it can be shown that the necessary and sufficient condition that a complex series may converge absolutely is that the series of the moduli of its terms converges. Such a series presents the same value if the sequence of its terms is rearranged according to any law whatever. Thus an infinite series of ascending powers of z the complex variable, $a_0+a_1z+a_2z^2+\ldots+a_nz^n+\ldots=f(z)$, with complex coefficients, is absolutely convergent for any value of z for which the series $A_0+A_1\rho+A_2\rho^2+\ldots+A_n\rho^n+\ldots$ formed by the moduli of its terms is convergent; and *vice versa.* In geometric language, if such a series be absolutely convergent for the point corresponding to any value of z, it is absolutely convergent for all other points equally distant from the origin of co-ordinates; these are therefore situated on a circle. It is also absolutely convergent at all points within this circle, and therefore the region of convergence of this series is always a circle round the origin. The radius of the circle of convergence of a series is the greatest value of ρ for which the series of moduli converges. It is found by the condition that as n increases indefinitely we must have $\frac{A_{n+1}\rho}{A_n}<1$ or $\rho<\frac{A_n}{A_{n+1}}$. As the terms of an infinite series of powers are one-valued, the series itself, so long as it converges, is a one-valued function of the complex variable, which does not become infinite anywhere. It can also be proved that this function is continuous: that is, if z and $z\pm\delta$ be values of z for which it converges, then $\lim[f(z\pm\delta)-f(z)]=0$, when $\delta=0$.

8. When a variable quantity depends upon two others in such a way that, if their values are given, its value is known, it is of course a function of them; but, inasmuch as for real values of x and y, when $z(=x+iy)$ is given, we know both x and y, Cauchy considered any function $F(x,y)$ to be a function of z. On the other hand, Riemann considered a function $F(x,y)$ to be one of z when it contains x and y only in the combination $x+iy$. In fact, if we have $dF=\frac{\delta F}{\delta x}dx+\frac{\delta F}{\delta y}dy$ for any indefinitely small increments dx and dy, inasmuch as this may be written

$$dF=\frac{1}{2}\left(\frac{\delta F}{\delta x}+i\frac{\delta F}{\delta y}\right)(dx-idy)+\frac{1}{2}\left(\frac{\delta F}{\delta x}-i\frac{\delta F}{\delta y}\right)(dx+idy)$$

and if dF must always be zero as long as $d(x+iy)$ vanishes, then we must have $\frac{\delta F}{\delta x}+i\frac{\delta F}{\delta y}=0$. This, which is the condition that, when x and y are perfectly unrestricted (and so may each be complex), they may enter only in the combination $x+iy$, must also hold when they can both admit only real values, in order that F may be in Riemann's sense a function of z. Cauchy called the function *monogène* when it satisfies this relation. The further significance of this relation is seen if we put $dx=\rho\cos\theta$ and $dy=\rho\sin\theta$, whence

$dz = \rho e^{i\theta}$ and $dx - idy = \rho e^{-i\theta}$; for then in general $\frac{dF}{dz} = \frac{1}{2}\left(\frac{\delta F}{\delta x} + i\frac{\delta F}{\delta y}\right)e^{-2i\theta} + \frac{1}{2}\left(\frac{\delta F}{\delta x} - i\frac{\delta F}{\delta y}\right)$ depends not only on the value of z but also on the direction θ of the adjacent point. When $\frac{\delta F}{\delta x} + i\frac{\delta F}{\delta y} = 0$ we have $\frac{dF}{dz} = \frac{\delta F}{\delta x} = \frac{1}{i}\frac{\delta F}{\delta y}$: that is, for each point z, in case the function is *monogeneous*, there is a derived function with regard to the complex variable, independent of the direction in which this variable is supposed to change. If the relation do not hold, there is a different derived for each such direction. When we separate F into its real and imaginary parts, we may write $F = u + iv$, and the preceding relation becomes $\frac{\delta u}{\delta x} - \frac{\delta v}{\delta y} + i\left(\frac{\delta v}{\delta x} + \frac{\delta u}{\delta y}\right) = 0$, whence $\frac{\delta u}{\delta x} - \frac{\delta v}{\delta y} = 0$ and $\frac{\delta u}{\delta y} + \frac{\delta v}{\delta x} = 0$. Hence further $\frac{\delta^2 u}{\delta x^2} + \frac{\delta^2 u}{\delta y^2} = 0$ and $\frac{\delta^2 v}{\delta x^2} + \frac{\delta^2 v}{\delta y^2} = 0$.

9. A function of a complex variable which is continuous, one-valued, and has a derived function when the variable moves in a certain region of the plane is called by Cauchy *synectic* in this region, and by Briot and Bouquet[1] *holomorphe*, to indicate that it is like an integer function, for which this property holds throughout the entire plane. Weierstrass styles it an *analytic* function. The property that dw/dz is independent of dy/dx furnishes a geometrical relation between the figure which w describes in its plane and that which z describes. In fact, let values w_1, w_2, w_3 correspond to the values z_1, z_2, z_3, then, if $\frac{w_3 - w_1}{w_2 - w_1} = \frac{z_3 - z_1}{z_2 - z_1}$, as already observed, the triangle for the values w is similar and similarly placed to that for the values z; in that case $\frac{w_3 - w_1}{z_3 - z_1} = \frac{w_2 - w_1}{z_2 - z_1}$. But, if we suppose z_3 to close up to z_1, then w_3 closes up to w_1, and, if z_2 close up to z_1, w_2 closes up to w_1. In the limit the equality of these quotients for all directions of variation of z shows that the figure which w describes in its plane is in its infinitely small parts similar to that described by z, and two intersecting curves in the plane of w cut at the same angle as the corresponding curves in the plane of z, provided always that dw/dz is neither zero nor infinity.

10. Let $z + h$ be a complex value within the circle of convergence of the series $f(z) = a_0 + a_1 z + a_2 z^2 + \ldots + a_n z^n + \ldots$, then we have $f(z + h) = a_0 + a_1(z + h) + a_2(z + h)^2 + \ldots + a_n(z + h)^n + \ldots$ Now, if we arrange this absolutely convergent series by powers of h, the coefficients are infinite series which can be proved to be the successive derived functions of $f(z)$: thus, when a one-valued function $f(z)$ can be expanded in a series of powers of z, the expansion can be made only in a single manner. We have therefore $f(z + h) = f(z) + \frac{h}{1}f'(z) + \frac{h^2}{\underline{|2}}f''(z) + \ldots + \frac{h^n}{\underline{|n}}f^{(n)}(z) + \ldots$, which is Taylor's theorem for a function given by an infinite series of powers of a complex variable.

11. We proceed to examine at how many points within a circle of convergence of radius R the function $f(z)$ vanishes, *i.e.*, has a root. In the first place it can be shown that, if R be finite, the function cannot vanish at infinitely many points in the circle without vanishing identically, that is, being zero everywhere in the circle. Hence we can only have a finite number of roots in any finite portion of the plane, and we may suppose none of these to lie upon the boundary circle. If the function vanish at any point z_1, then, when we take the expansion $f(z) = f(z_1 + z - z_1) = f(z_1 + \frac{z - z_1}{1}f'(z_1) + \frac{(z - z_1)^2}{1.2}f''(z_1) + \text{etc.}$, we have $f(z_1) = 0$. We may also have $f'(z_1) = 0$, $f''(z_1) = 0$, etc. Suppose that the first of these which does not vanish is $f^{(\alpha)}(z_1)$, or that the function $f(z)$ vanishes for $z = z_1$ to the order α, then $\frac{f(z)}{(z - z_1)^\alpha} = \frac{1}{\underline{|\alpha}}f^{(\alpha)}(z_1) + \frac{z - z_1}{\underline{|\alpha + 1}}f^{(\alpha + 1)}(z_1) + \text{etc.}$ Now let this quotient be rearranged according to powers of z, and suppose the function to vanish at z_2 to the order β, we can expand by powers of $z - z_2$, whence we get $\frac{f(z)}{(z - z_1)^\alpha (z - z_2)^\beta \ldots}$, ultimately $= \phi(z)$, a series not vanishing anywhere within the region. If $f(z)$ were a rational integer algebraic function, we should find $\phi(z)$ a constant, and we see that $\alpha + \beta + \ldots$ etc. $= n$: that is, such a function cannot have more than n roots in the region of convergence, *i.e.*, in the entire plane. Taking logarithms, we have $\log f(z) = \alpha\log(z - z_1) + \beta\log(z - z_2) + \ldots + \log\phi(z)$. Hence, taking for each logarithm on the right one of its innumerable values, let z move from any point A round the circumference of the boundary circle, keeping its interior on the left. Since $z - z_1$ vanishes only once within the circle, namely, for $z = z_1$, $\log(z - z_1) = \log\rho + i\theta$ will become $\log\rho + i(\theta + 2\pi)$ when z returns to A. Similarly $\log(z - z_2)$ will differ from its initial value by $2i\pi$; and so for the others. But, as $\phi(z)$ does not vanish anywhere in the circle, $\log\phi(z)$ will return to its original value at A. Hence, if there be ν vanishing points or roots within the circle of convergence, the value of $\log f(z)$ changes by $2i\pi\nu$, when z travels all round the circumference. Conversely, if the logarithm alter by $2i\pi\nu$ as z travels round the circle of convergence, the number of roots within the circle is ν.

12. This theorem of Cauchy's at once leads to the fundamental theorem of algebra, that every equation of the nth degree $f(z) = a_0 + a_1 z + a_2 z^2 + \ldots + a_n z^n = 0$ has n complex roots. For we can take the radius of the circle so great that the value of $a_n z^n$ far exceeds that of the other terms; and, writing $f(z) = a_n z^n (1 + P)$, the modulus of P can be made as small as we please. Hence $\log f(z) = \log(a_n z^n) + \log(1 + P)$. Now as we go round the circle $\log(1 + P)$ differs as little as we please from $\log(1) \pm 2ki\pi$, and so, whatever value we begin with, as the corresponding logarithm varies continuously, the value of $\log(1 + P)$ will not have changed by a multiple of $2\pi i$ when we return to the point we set out from. But, since the point $z = 0$ is within the circle, $\log(a_n z^n) = n\log(a_n^{\frac{1}{n}} z)$ changes its argument by $n.2\pi i$ in consequence of the circuit. Hence $\log f(z)$ changes by $2\pi in$: that is, in the circle of convergence whose radius is as large as may be required there are always n values for which the rational function $a_0 + a_1 z + a_2 z^2 + \ldots + a_n z^n$ vanishes. Some of these may be coincident; but in all cases the total number of the orders of the different vanishings is n.

13. If two given points z_0 and Z be joined by any curve of finite length, and if we take as many intermediate points as we please $z_1, z_2, \ldots z_{n-1}$ upon the curve and form the sum $f(z_0)(z_1 - z_0) + f(z_1)(z_2 - z_1) + f(z_2)(z_3 - z_2) + \ldots + f(z_{n-1})(Z - z_{n-1})$, then the complex limiting value to which this sum tends as n is increased indefinitely is called the *definite integral* of the function $f(z)$, formed from z_0 to Z *along the path* prescribed by the equation of the curve. Having first examined, after the manner of the theorems regarding real integrals, under what conditions this sum has a determinate limiting value, we have next to take into account that a definite complex integral differs essen-

---

[1] The word *monodrome* is used by Cauchy and *monotrope* by Briot and Bouquet to indicate the case in which, supposing z has to move in a certain region, all the paths that lead from an initial point z_0 to any point z within the region lead to one and the same value of w; in other cases w will be *polytrope*. When w is *holomorphe* in a region except at a point z_1, where it becomes infinite without $1/w$ ceasing to be *holomorphe* near this, this point is called a *pole* or an *infinity* of w. A rational fraction has the roots of its denominator as poles; and a function otherwise *holomorphe* having poles is called by these writers *méromorphe*. Some writers prefer the terms *integer* and *fractional* functions.

tially from a real one in that the path along which the variable z may travel from one limit to the other is perfectly arbitrary. We have therefore to investigate this problem: When is the integral of a complex function a unique function of its superior limit independent of the path of integration? In order to answer this we must recall an important theorem concerning the reduction of a double integral of a function to simple integrals along the boundary curve, which is in fact a case of Green's theorem (see INFINITESIMAL CALCULUS, vol. xiii. p. 63) when confined to two variables.

14. Suppose P and Q are two real functions of x and y which are everywhere within a certain boundary finite and continuous, the theorem is then that the double integral $\iint\left(\frac{\delta Q}{\delta x}-\frac{\delta P}{\delta y}\right)dxdy$ taken over the entire region is equal to the simple integral $\int(Pdx+Qdy)$ taken along the entire boundary of the region.

Taking the positive directions of the axes as usual, we define the positive direction along the boundary to be that for which the bounded surface is on the left hand; then, if we have to exclude any portion, *e.g.*, a circular space altogether within the external boundary, so that the points within it are to be regarded as not included in the region, the positive direction of the boundary is that indicated by the arrows in Fig. 4. In all the simple integrals the integration must be effected in the positive direction thus explained.

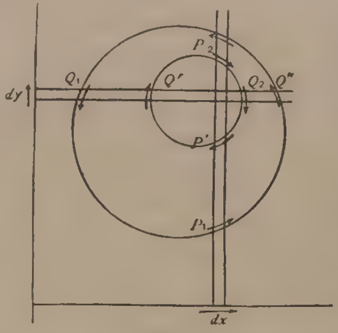

FIG. 4.

To integrate $\iint\frac{\delta Q}{\delta x}dxdy$ with respect to x, let us split up the region into elements by parallels to the axis of x. Select any one and, reading from left to right, denote the values of Q where the element crosses the boundary at the entrances by Q_1, Q_2, etc., and at the exits by Q', Q'', etc.; then $\int\frac{\delta Q}{\delta x}dx=-Q_1+Q'-Q_2+Q''-\text{etc.}$, and thus $\iint\frac{\delta Q}{\delta x}dxdy=$

$$\int-Q_1dy+\int Q'dy+\int-Q_2dy+\int Q''dy-\text{etc.}$$

Now in each of these integrals y goes through all its values from the least to the greatest, therefore dy is always to be taken positively. But, denoting by dy_1, dy_2, etc., and by dy', dy'', etc., the projections on the axis of y of the arcs of the boundary cut by the element as above, when we take the positive direction of the boundary into account, we have $dy=-dy_1=-dy_2=\text{etc.}=+dy'=+dy''=\text{etc.}$; thus

$$\iint\frac{\delta Q}{\delta x}dxdy=\int Q_1dy_1+\int Q'dy'+\int Q_2dy_2+\text{etc.}=$$

$\int Qdy$, where this is taken along the entire boundary in the positive direction. In like manner, dividing the region into elements parallel to the axis of y, and denoting the values of P at the entrances, proceeding from below upwards, by P_1, P_2, etc., and at the exits by P'. P'', etc., we have

$$\iint\frac{\delta P}{\delta y}dxdy=-\int P_1dx+\int P'dx-\int P_2dx+\text{etc.},$$

where dx is positive. Hence, as before, taking account of the positive direction of the boundary, $dx=+dx_1=+dx_2=\text{etc.}=-dx'=-dx''=\text{etc.}$, and consequently $\iint\frac{\delta P}{\delta y}dxdy=-\int P_1dx_1-\int P'dx'-\int P_2dx_2-\text{etc.}=-\int Pdx$, taking the integral in the positive direction along the entire boundary. Accordingly, putting these both together, we have the surface integral $\iint\left(\frac{\delta Q}{\delta x}-\frac{\delta P}{\delta y}\right)dxdy=\int(Pdx+Qdy)$, taken positively along the entire boundary. This proposition may be extended to complex values: when $P=P'+iP''$ and $Q=Q'+iQ''$, as the proposition is already proved for real values, we can put $\iint\left(\frac{\delta Q}{\delta x}-\frac{\delta P}{\delta y}\right)dxdy$

$$=\iint\left(\frac{\delta Q'}{\delta x}-\frac{\delta P'}{\delta y}\right)dxdy+i\iint\left(\frac{\delta Q''}{\delta x}-\frac{\delta P''}{\delta y}\right)dxdy;$$

then, applying it to each of these, $\iint\left(\frac{\delta Q}{\delta x}-\frac{\delta P}{\delta y}\right)dxdy$

$$=\int(P'dx+Q'dy)+i\int(P''dx+Q''dy)=$$

$\int(Pdx+Qdy)$. We assumed that there were no branch-points within the region, or other points at which P or Q are discontinuous. If there were such, we should have to surround them with actual closed lines, as small as we please, and thus exclude them, introducing these lines as parts of the boundary of the region.

15. We can now let $P=f(z)$, $Q=if(z)$. We see that, if $f(z)$ be an analytic function of z without exception in any simply connected region, $\int f(z)dz=0$ when taken all round the boundary of that region. If we take any two paths from z_0 to Z in this region, since these paths from z_0 through A to Z and back through B to z_0 include such a region, we have $I(z_0AZBz_0)=0$ or $I(z_0AZ)+I(ZBz_0)=0$. But, as the value of the integral $I(ZBz_0)=-I(z_0BZ)$ along the same path, the last equation becomes $I(z_0AZ)=I(z_0BZ)$, or the value with which the integral starting from z_0 arrives at Z is independent of the path travelled under the conditions supposed: it is a function of the upper limit only. The path z_0BZ is said to be *reconcilable* with the path z_0AZ. If the region within which $f(z)$ is an analytic function be multiply connected, $\int f(z)dz$ vanishes when taken positively all round the boundary. The integral has a definite value along each separate boundary curve. For instance, if within the region we take a closed curve which includes a simply connected region, as α in Fig. 5, the integral along this curve vanishes. But for a curve which includes a region along with a boundary curve, as β in Fig. 5, the integral has the same value as it has for this boundary curve. Whence, if a function $f(z)$ which has to be integrated lose the character of an analytic function in isolated places, these must be excluded by surrounding them by curves as near them as we please and taking these curves as part of the boundary; it can then be integrated in the multiply connected region so found. The integral for the boundary of such a place may vanish or not. If not, the integral function is many-valued and branches at this place. If it vanish, the inte-

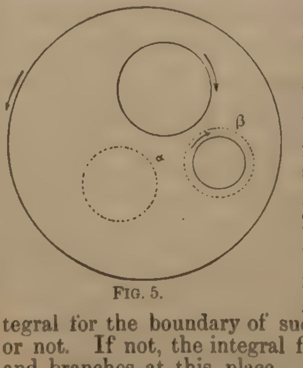

FIG. 5.

gral remains one-valued, but the point may still be a singular one for the integral: that is, the integral may at it cease to be finite or to be an analytic function.

16. If we know the value of any function and those of all its derived functions at any one point, and if we know that it is an analytic function within a finite connected region,—that is, that it is unique, continuous, and has a determinate first derived,—then Taylor's series for it converges throughout a circle round this point, which is included within the region; and for each point within the region the function can be developed in a similar series. In other words, every function which is analytic without exception in a connected region can be expanded around each point of the region in a series of ascending positive integer powers. The method in which we show this is due to Cauchy. Let $f(z)$ be an analytic function without any exception in a simply connected region (including the boundary); then, if $t = u + iv$ be any point within the region, the quotient $\frac{f(z)}{z-t}$ is likewise an analytic function within the region, only the point $z = t$ is a singular one. Surrounding t by a circle whose radius ρ is as small as we please, we obtain a region bounded by two curves in which the quotient is analytic without exception. Hence, integrating the quotient along both boundaries, the sum of both integrals vanishes. In regard to the small circle put $z - t = \rho e^{i\theta}$; therefore we get $dz = i\rho e^{i\theta} d\theta$, and for it $\int \frac{f(z)}{z-t} dz = -i \int_0^{2\pi} f(t + \rho e^{i\theta}) d\theta$. Now f is continuous near $z = t$. Hence ρ can be taken so small that for all values of θ the difference of $f(t)$ and $f(t + \rho e^{i\theta})$ may be less than δ, where the modulus of δ is as small as we please. Hence $i \int_0^{2\pi} f(t + \rho e^{i\theta}) d\theta$ and $i \int_0^{2\pi} f(t) d\theta = 2i\pi f(t)$ differ by a quantity whose modulus is less than that of $2\pi\delta$: thus, whatever be the value of ρ, we have $i \int_0^{2\pi} f(t + \rho e^{i\theta}) d\theta = 2i\pi f(t)$. Hence we have $\int \frac{f(z)}{z-t} dz - 2i\pi f(t) = 0$, or $f(t) = \frac{1}{2i\pi} \int \frac{f(z)}{z-t} dz$, when the integral is taken positively along the outer boundary, and so along any curve which includes the point t. This is what Cauchy called the *residue* of the quotient function relative to its infinite t. We thus see that, when the values of a function $f(z)$ are given along a closed curve, and the function is analytic without exception within this curve, the value of $f(z)$ can be found for each internal point by means of a definite integral.

It was assumed that $f(z)$ has throughout a derived. This can be exhibited as a definite integral. In fact

$$\frac{f(t + \triangle t) - f(t)}{\triangle t} = \frac{1}{2i\pi} \int f(z) \frac{dz}{(z - t - \triangle t)(z - t)};$$

whence, letting $\triangle t$ converge to zero, $f'(t) = \frac{1}{2i\pi} \int \frac{f(z) dz}{(z-t)^2}$, where the integral may be taken along any path round t, provided it remain within the original region. But it follows that throughout this $f'(t)$ also is an analytic function, for, as before, $f''(t) = \frac{2.1}{2i\pi} \int \frac{f(z) dz}{(z-t)^3}$. In like manner $f^{(n)}(t) = \frac{\underline{|n}}{2i\pi} \int \frac{f(z) dz}{(z-t)^{n+1}}$. Thus for all points in the region the function has higher deriveds of all orders, and they are all analytic functions.

17. We can now develop the function $f(t)$ in a series of powers. Let us select a point a, otherwise arbitrary, such that the largest possible circle which can be drawn round it without going outside the region may include the point t, for which the function is to be expanded. For every point on the circumference of this circle we have $\text{mod}(t - a) < \text{mod}(z - a)$; and therefore $\frac{1}{z-t} = \frac{1}{z-a} \frac{1}{1 - \frac{t-a}{z-a}} = \frac{1}{z-a} \left\{ 1 + \frac{t-a}{z-a} + \frac{(t-a)^2}{(z-a)^2} + \frac{(t-a)^3}{(z-a)^3} + \ldots \right\}$ is a convergent series. Now, substituting this in the equation $f(t) = \frac{1}{2i\pi} \int \frac{f(z)}{z-t} dz$ and taking the circle as curve of integration, we find $f(t) - \frac{1}{2i\pi} \left\{ \int \frac{f(z)}{z-a} dz + (t-a) \int \frac{f(z)}{(z-a)^2} dz + (t-a)^2 \int \frac{f(z)}{(z-a)^3} dz + \text{etc.} \right\}$, which by the equations already established may also be written $f(t) = f(a) + (t-a)f'(a) + \frac{(t-a)^2}{1.2} f''(a) + \frac{(t-a)^3}{1.2.3} f'''(a) + \ldots$ This expansion converges unconditionally for all values of t within the circle round a which does not go outside the original region. This is Taylor's series for a complex function, and this deduction of it shows definitely how far its convergence extends, namely, to all points t which are less distant from a than the nearest point of discontinuity or of ramification. Thus a function whose value, as well as those of all its derived functions, is known for a point is analytic in the neighborhood of this point only when a finite circle, however small, can be assigned within which this series converges. The series arrived at will, in general, not converge for all values of t within the original region in which $f(z)$ was assumed to be analytic. But we can vary the centre a so as to arrive at a circle, and thereby at a development, which embraces any such required point. If t be at a finite distance, however small, from the circle, draw any curve from a to t which shall be always at a finite distance from the boundaries. Let the circle round a meet this curve in the point a' between a and t: then by means of the series we can calculate the function f and its deriveds for a point on the curve and within the circle as near as we please to a', and thus take this as the centre of a new development all whose coefficients are known. The new circle of convergence cuts the curve in a point a'', which is certainly nearer to t. The continuation of this process must ultimately lead to a circle which includes the point t, since the radii cannot diminish below a finite assignable quantity, the path $a\ a'\ a'' \ldots t$ being always at finite distance from the boundaries. By this process we can also carry on an analytic function that is defined by a series of powers beyond its circle of convergence into a region which does not contain any singular point. Each such series of powers defines the function for a determinate circular region of convergence, and is said to be an *element* of the function. Different elements of the function are got according to the centre chosen for the expansion, and

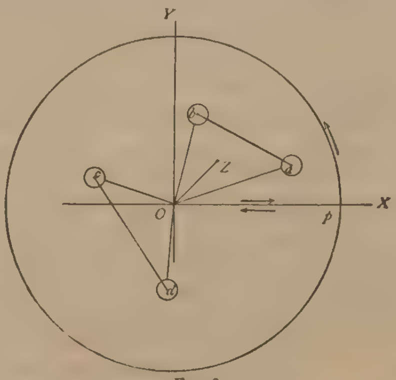

FIG. 6.

even the same value of the argument belongs to different elements of the function; but for a unique function the different elements must lead to the same value for the same argument. Two or more analytic functions, however defined within given regions, are to be regarded as belonging to the same function only when the elements of one function can be derived from those of the others.

18. We conclude with illustrating by a few applications to elliptic functions of a complex variable. Calling $R(z)=(z-a)(z-b)(z-c)(z-d)$, then $\sqrt{R(z)}$ will be expressed as a unique function by means of a two-leaved Riemann's surface. Its branches take the same values at each of the points a, b, c, d. Let the leaves be pierced through and joined transversely along the lines a to b and c to d (Fig. 6). Assume that in the upper leaf $\sqrt{R(z)}$ at the origin is $+R$ and in the under leaf is $-R$. Every path which, when projected on the upper leaf, goes an odd number of times round an odd number of branch-points leads from one leaf into the other; on the other hand, a path which goes an even number of times round an odd number of branch-points, or which goes round an even number of branch-points, ends in the leaf in which it originally began. Now let us investigate what changes in value accrue to $\int\frac{dz}{\sqrt{R(z)}}$ and to $\int\sqrt{R(z)}dz$ when z describes part of a vanishing circle round the branch-point a. First, let $z=a+\rho e^{i\theta}$, then $dz=i\rho e^{i\theta}d\theta$, $R(z)=\rho e^{i\theta}(a-b+\rho e^{i\theta})(a-c+\rho e^{i\theta})(a-d+\rho e^{i\theta})=\rho e^{i\theta}S$. Hence $\frac{dz}{\sqrt{R(z)}}=i\rho^{\frac{1}{2}}e^{i\theta/2}\frac{d\theta}{\sqrt{S}}$ and $\sqrt{R(z)}\,.\,dz=i\rho^{\frac{3}{2}}e^{\frac{3}{2}i\theta}d\theta\sqrt{S}$. But, when ρ is evanescent, $\lim\sqrt{S}=\sqrt{[(a-b)(a-c)(a-d)]}=T$, and is therefore neither infinitely great nor evanescent; integrating therefore between θ_0 and θ_1, we find $\lim\sqrt{\rho}\,.\,\frac{i}{T}\int_{\theta_0}^{\theta_1}e^{i\theta/2}d\theta$ and $\lim\sqrt{\rho^3}\frac{i}{T}\int_{\theta_0}^{\theta_1}e^{\frac{3}{2}i\theta}d\theta$. Since these vanish when ρ does, and the other factors are not infinite, we see that, when $\int\frac{dz}{\sqrt{R(z)}}$ and $\int\sqrt{R(z)}dz$ are taken along paths surrounding indefinitely closely a single branch-point, both these integrals vanish.

If now we confine our attention to the integral of the first kind, let z go from the origin in the upper leaf along a straight line to near the point a; then the integral $\int\frac{dz}{\sqrt{R(z)}}$, putting $y=mx$ in $z=x+iy=(1+im)x$, may be calculated as for a real variable, and it increases by $\int_0^a\frac{dz}{\sqrt{R(z)}}$. Next let z go round a in a vanishing circle, the integral gains nothing; then let z return to the origin along the same line, it proceeds now in the lower leaf; thus both $\sqrt{R(z)}$ and dz have signs opposite, but values equal to, what they had on the outward path. Thus on the whole by travelling this elementary contour (*lacet*, *Schleife*) from O to near a, round a, and back to O, the value of the integral is increased by $A=2\int_0^a\frac{dz}{\sqrt{R(z)}}$. In like manner we have for the elementary contours or loops round b, c, d the three increments $B=2\int_0^b\frac{dz}{\sqrt{R(z)}}$, $C=2\int_0^c\frac{dz}{\sqrt{R(z)}}$, and $D=2\int_0^d\frac{dz}{\sqrt{R(z)}}$.

19. Now, if the loop round a be described twice in succession, the integral changes by $A-A=0$ and so on. But if, after a is once described, b is described once, the change is $A-B$. If then z go straight to any arbitrary point for which the value of the rectilinear integral is w, the value along the entire path, or along any path reconcilable with it, is $A-B+w$. The two loops round a and b may be taken as often as we please before going by the straight course from O to z; thus $A-B$ is a *period* of the integral, which is accordingly an infinitely many-valued function of z. As there are three independent differences of any four quantities, it would seem as if there should be three periods; but we can show that $A-D$ arises from a combination of $A-B$ and $A-C$. In fact, describe round the origin a circle to include all the four points; then let z go straight from the origin to a point p on this circle, travel round it positively, and return from p to the origin. The integral has along this path the same value as along the four loops in succession, since between the two paths there is not any singular point and both have the same origin and goal. Thus the value of the integral along this path is $A-B+C-D$. But, when z goes round the circle from p, the radical changes sign four times. If loops be described from p round a, b, c, d, they are reconcilable with the circumference of the circle. Hence the radical has the same sign when it returns to p as that it set out with; accordingly, since along Op and pO the radical has the same sign, the integrals $I(\mathrm{O}p)$ and $I(p\mathrm{O})$ cancel, and the integral along the four loops in succession has the same value as along the circle alone. To find this value, put $z=\rho e^{i\theta}$ and it becomes

$$\frac{i}{\rho}\int_{\theta_0}^{\theta_0+2\pi}\frac{e^{i\theta}d\theta}{\sqrt{\left(e^{i\theta}-\frac{a}{\rho}\right)\left(e^{i\theta}-\frac{b}{\rho}\right)\left(e^{i\theta}-\frac{c}{\rho}\right)\left(e^{i\theta}-\frac{d}{\rho}\right)}}$$

But, as the radical is unique along the circumference of the circle, the value of this integral is the same whatever be the value of ρ, provided it be large enough to include all the singular points. Hence we can let ρ increase indefinitely and then this has the limiting value zero. Consequently $A-B+C-D=0$, or $A-D=A-C-(A-B)$; thus the third period is composed from the other two. Hence the periods reduce to $A-B$ and $A-C$. It can thus be shown that all values of the integral for all possible paths of integration between O and z are included in the two formulæ $m(A-B)+n(A-C)+w$ and $m(A-B)+n(A-C)+A-w$.

20. If a new variable z' be introduced, homographically related to z by the equation $\alpha+\beta z'+\gamma z+\delta zz'=0$, it transforms the integral $\int\frac{dz}{\sqrt{R(z)}}$ into $(\alpha\delta-\beta\gamma)\int\frac{dz'}{\sqrt{R_1(z')}}$. The coefficients of $R_1(z')$ can be determined so that it may differ only by a constant multiplier from $(1-z'^2)(1-k^2z'^2)$. As k is given by a reciprocal quadratic equation, it is always possible to choose such a value that its modulus may be less than 1. In other words, it is possible by a homographic transformation to convert the quadrilateral a, b, c, d into a parellelogram, the new origin being at the intersection of its diagonals (Fig. 7). This leads to Jacobi's form of the integral when k is supposed real. The integrals along the loops are here $A=2\int_0^1\frac{dz}{\sqrt{(1-z^2)(1-k^2z^2)}}$,

$$B=2\int_0^{1/k}\frac{dz}{\sqrt{(1-z^2)(1-k^2z^2)}},$$

$$C=2\int_0^{-1}\frac{dz}{\sqrt{(1-z^2)(1-k^2z^2)}},$$

$$D=2\int_0^{-(1/k)}\frac{dz}{\sqrt{(1-z^2)(1-k^2z^2)}}.$$ Hence $A-C=2A$.

$A-B$ is the integral taken consecutively along the loops of a, b; but for these paths we may substitute the following: proceed straight from O to α near a, then round a back to α, then straight from α to β near b, next round b back to β, then again straight to α, and

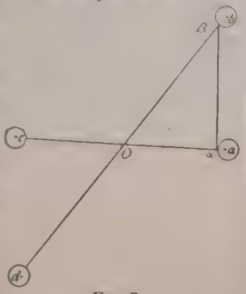

FIG. 7.

straight back to O. The integral takes the same value by this path as by the other, since there is no singular point between them and both paths have the same origin and goal. Now the radical changes sign as z goes round a, and again as it goes round b; hence it returns to a with the same sign. Thus Oa is travelled in the two directions with the root having the same sign; hence $I(Oa)$ and $I(aO)$ cancel. By decreasing indefinitely the radii of the circles, the circular integrals vanish; and, as the root is negative along $a\beta$ and positive along βa, the value of $A-B$ reduces to the negative double value of the integral from a to β, that is, from a to b for vanishing radii; thus $A-B=-2\int_1^{1/k}\frac{dz}{\sqrt{(1-z^2)(1-k^2z^2)}}$. The rectilinear integrals required are now only between the limits 0, 1, and $1/k$, so that they do not cross any singular point. In case k is a positive proper fraction we have in Jacobi's notation $A=2K$, $A-C=4K$, $A-B=2iK'$; therefore all values of the elliptic integral $\int_0^z\frac{dz}{\sqrt{(1-z^2)(1-k^2z^2)}}$, whatever be the path taken between the limits 0 and z, are included in the two formulæ $4nK+2miK'+w$ and $4nK+2miK'+2K-w$. Hence the inverse function $z=\sin am\, w$ is doubly periodic for $4K$ and $2iK'$, thus—

$$\sin am(4nK+2miK'+w)=\sin am\, w$$
$$\sin am(2(2n+1)K+2miK'-w)=\sin am\, w.$$

This last shows that $\sin am\, w$ takes the same value for two different values of w within the same period. In fact, in the plane of w measure a series of parallels (see Fig. 8) to the axis of ordinates at distances $4K$, and to the prime axis at distances $2K'$, then the plane will be divided into rectangles such that in each $\sin am\, w$ goes through all its values and has equal values at corresponding points of different rectangles: thus, whatever it is at P for $w=u+iv$, it is the same again at P_1, P_2, and P_3; at Q, where $w=2K-u+i(2K'-v)$, it has the same value; at R, where $w=2K+u+iv$, and at S, where $w=4K-u+i(2K'-v)$, it has the equal and opposite negative value. The value of $\sin am\, w$ vanishes at the points marked in Fig. 8 by circles and is infinite at those denoted by crosses.

(B. W.)

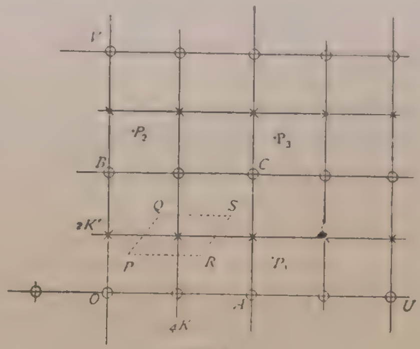

FIG. 8.

VARIATION AND SELECTION.

It is not proposed in the present article to trace the successive steps by which the general doctrine of the origin of species by descent with modification has come to gain acceptance among naturalists (see EVOLUTION). The present problem is concerned solely with the determinant factors of evolution, with searching out the mechanism of the evolutionary process, and of discerning if possible such order as may lie under the apparent flux of change. Yet a brief retrospect of the essential views of successive evolutionists is still necessary, but only in so far as these have been concerned, not simply with the empirical evidence for descent with modification, but with the deeper attempt to explain the rationale of this process, to show how it is that modifications come to arise, persist, and increase at all. In other words, just as there are these two essential aspects of the doctrine of evolution, which must on pain of immediate confusion be clearly kept apart, so it is necessary to distinguish between the corresponding sides of its historical development, and, passing beyond the simple hypothesis and evidences of descent, consider the attempts to explain the actual process of modification.

Theories of Variation.

Buffon.

If we pass over the speculations of the earliest evolutionists—De Maillet, Maupertuis, Robinet, Bonnet, etc.,—as too vague for rapid summary, and note that Linnæus was not quite a consistent creationist, since he admitted that many species may be simply fertile hybrids, the history of definite speculation as to the factors of variation may be fairly said to begin with Buffon, whose distinct though covert suggestion of the doctrine of descent with modification was supported by emphatic insistence upon the inportance of external conditions. He endeavored to show how "natures, instincts, and most inward qualities" are modified through bodily habits, how new functions seem to arise in response to new conditions, and how changes in climate, food, and other conditions of life bring about direct modifications in organisms exposed to them. Kant, on the other hand, viewed the evolution of species as related essentially to the mechanical laws of the organism itself, although in his latest writings he allowed for the influence of geographical distribution, food, etc., noted the importance of selection in artificial breeding, and even hinted at the notion of struggle for existence, which was soon afterwards more clearly emphasized by Herder (*Ideen z. Phil. d. Geschichte*, 1790) in a striking passage, which may be briefly quoted in free translation: "All is in struggle, each one for himself. . . . Space is too small for the number. . . . Each genus looks after itself as if it were the only one. . . . In this way the whole was preserved. . . . Thus were forces cradled, and limbs counted, and tendencies determined, and the earth came to bear what it could."

Kant.

Herder.

Erasmus Darwin.

Erasmus Darwin (*Zoonomia*, 1794) believed that the organism has the faculty of improving by its own inherent activity, that it has the power of attaining new parts attended with new propensities. Yet the strongest and most active animals are those which propagate and hand on improvements. Transformations, too, may be produced in part by the exertions of the organism in consequence of its desires for food, security, and reproduction. Changed conditions, such as climate, have an indirect influence in changing desires, and thus actions, and so finally structure; and they may also operate directly.

Treviranus. Treviranus (1802–1831) assumed an indefinite variability of the organism, with considerable power of adaptation to surroundings, and even anticipated much recent speculation in his suggestion of a possible factor of modification in the union of sexual elements. **Lamarck.** The well-known theory of Lamarck (1801–1809) laid special emphasis on function and environment; for, though the sense of need in association with suitable environment calls out a succession of efforts, and so originates incipient structural modifications, it is to increased functioning that the increase of these modifications must be ascribed, while similarly disuse explains degeneration. Changed conditions produce new wants, nutritive and reproductive; hence changes in climate, or the like, change the organism by changing its habits. Rapid increase is checked by other organisms: the strongest and best-armed for attack devour the weaker, and the less perfect genera are kept down by the more perfect. **Goethe.** The less definite view of Goethe included, besides recognition of the conservative or centripetal force of heredity, that of a progressive or centrifugal tendency to adaptation to environment. **Oken.** Oken (1809) similarly regarded all progress from his primeval "Urschleim" as having been in terms of its interaction with the external conditions of life. **Wells and Matthew.** In 1813 Wells made his now well-known suggestion of the importance of natural selection in determining the varieties of the human species; and in 1831 Patrick Matthew published his much more developed, yet equally disregarded, statement of the same doctrine in its more general applications. **The St.-Hilaires.** In 1828–30 Geoffroy St.-Hilaire, afterwards ably succeeded by his son Isidore, denied indefinite variation, regarding function as of secondary importance, and laying special stress on the direct influence of the environment: for instance, it was not so much the effort to fly as the (supposed) diminished proportion of carbonic acid in the atmosphere which determined the evolution of birds from saurians. **Von Buch.** The veteran geographer Von Buch naturally inclined to emphasize the influence of geographical isolation (locality, climate, soil, food, etc.), and laid stress on the restriction of the area of possible sexual union as bearing upon the origin of varieties. **Von Baer.** **Schleiden.** The embryologist Von Baer (1834) dwelt especially upon the organismal nature of variation, on the unfolding, as it were, of new structures; and M. J. Schleiden (1838) and other naturalists more or less distinctly advanced similar opinions. In 1844 appeared the *Vestiges of Creation*, which in its later editions (1853) formulated an hypothesis of progress (1) by rhythmic impulse through grades of organization, (2) by another impulse tending to modify organic structures in accordance with external circumstances. **Naudin.** In 1852 Naudin argued for the formation of new species in nature in a similar way to that of varieties under cultivation, further attaching great importance to an assumed "principle of finality," apparently a kind of organismal fate. **Herbert Spencer.** Herbert Spencer, whose weighty arguments for evolution date from 1852, laid special stress upon the modifying influences of environment, this involving changes of function, and so ultimately of structure. **Carus.** Finally, in 1853 Victor Carus argued for a progressive adaptation to changing external conditions. An undefined hypothesis of internal modifiability appears also to have floated before the mind of Owen.

Summary of these views. In this succession of variational theories we recognize the repeated general insistence upon every separate factor in the problem,—organism, function, and environment,—the successive authors, in fact, almost falling into as many schools. Yet these are singularly unprogressive: the same hypothesis is stated again and again, but always fails to carry conviction; many employ the merest abstractional explanations, in terms of what is simply the old prephysiological "vital force" (see BIOLOGY), or attempt to cut the knot by the more or less open introduction of a *deus ex machina*. Even the more definite and scientific theories of Erasmus, Darwin, Lamarck, Geoffroy, and Spencer fail adequately to establish in a sufficient number of concrete cases the supposed potency of environment or function, much less of internal or volitional moods, in determining extensive changes; moreover, they are constantly confronted by cases in which any one set of changes seems to take place independently of the other. Hence, despite the deep and unanimous conviction of so many biological thinkers as to the origin of species by evolution, the essential problem remained unsolved. For, until some explanation, rational and concrete, detailed yet universal, of the origin of species should be reached, the cautious naturalist could not feel justified in accepting as a scientific certainty a doctrine which rested so largely upon undemonstrable grounds. Any really new attempt at establishing the doctrine of evolution had thus, not simply to reorganize and strengthen the empirical evidence, by marshalling beside the generalizations of morphological unity of type the facts of more strictly historic bearing,—distributional, palæontological, and embryological,—but also to meet this deeper theoretic want by showing not only that evolution has taken place but how. **Charles Darwin.** Hence the importance and rapid acceptance of the *Origin of Species* (1859), for which the time was fully ripe. For it is evident from the preceding historical outline that the view still frequently promulgated of the exclusive and, as it were, catastrophic importance of this work in the establishment of the doctrine of evolution must be replaced by a more uniformitarian and, so to speak, less creationist view. It should not seriously be supposed that the theory of descent which had been held in one form or another by the leading biological thinkers of that and the two preceding generations, with almost the individual exception of Cuvier, had been decisively abandoned by men of science, or that the public which had purchased ten editions of the *Vestiges of Creation* in as many years, and which took up the first edition of the *Origin of Species* on the day of publication, could be quite unprepared for the acceptance of the major thesis of both works. Yet that a lull had taken place is also unquestionable, for the failure of wave after wave of speculative effort had produced a widespread feeling of discouragement, and a tendency to concentration upon more concrete and smaller (for the most part Linnæan or Cuvierean) problems alone, since of these the solution was comparatively sure. The dramatic coincidence between Darwin's and Wallace's conclusions[1] soon helped to gain immediate attention to the new theory; and this was thoroughly developed and retained by the prompt appearance of the first and second editions of the *Origin of Species*. Without entering upon a review of this classic treatise, much less a retrospect of the controversy it provoked, it is evident that it was upon almost all sides so much stronger than preceding attempts, its central doctrine so lucid and obvious a statement of the everyday facts of life, its mode of presentation so temperate yet so forcible, its self-criticism so frank and unconcealed, that its marvellous success was owing far more to intrinsic merit than favorable circumstances. The required re-statement of the evidence for the historic fact of evolution was at last learnedly and forcibly done, and the salient difficulties in its way, like that of the imperfection of the geological record, admirably met; yet this portion of the work sinks into comparative ineffectiveness beside the long sought *modal* explanation of the process proffered in the theory of natural selection, which was soon seen to throw a new and searching light upon the smallest details of structure, function, and distribution,—in fact, to afford the instrument of a new and systematic interpretation of organic nature. Of this doctrine, then, a brief account is needed, and this may be best given by following as closely as possible upon the lines of the *magnum opus* itself, although the full title of this—*The Origin of Species by means of Natural Selection, or the Preservation of Favored Races in the Struggle for Life*—is its own best and briefest summary.

---

[1] *Journ. and Proc. Linn. Soc.*, 1858.

Theory of Natural Selection.

Analysis of *Origin of Species.*

After mentioning that his first light upon the origin of species was derived from his early distributional studies, Darwin points out that "a naturalist, reflecting on the mutual affinities of organic beings, on their embryological relations, their geographical distribution, geological succession, and such other facts, might come to the conclusion that species had not been independently created, but had descended like varieties from other species. Nevertheless, such a conclusion, even if well founded, would be unsatisfactory until it could be shown how the innumerable species inhabiting this world have been modified so as to acquire that perfection of structure and co-adaptation which justly excites our admiration." Again, "It is therefore of the highest importance to gain a clear insight into the means of modification and co-adaption. At the commencement of my observations it seemed to me probable that a careful study of domesticated animals and cultivated plants would offer the best chance of making out this obscure problem. Nor have I been disappointed: in this and all other perplexing cases I have invariably found that our knowledge, imperfect though it be, of variation under domestication affords the best and safest clue." Hence the first chapter is devoted to an account of those extensive studies of variation under domestication which later formed the subject of a separate work.

Variation under domestication.

A comparison between individuals of the same variety of cultivated plants or animals shows a greater degree of variation than between individuals of any one species or variety in nature. This higher variability of domestic productions is to be ascribed to the less uniform conditions of their upbringing, perhaps in part also to excess of food. Exposure to new conditions must be continued for generations to set up any great variation; but this, once set up, continues indefinitely. Changed conditions may directly influence the whole organization or certain parts alone, or act indirectly through the reproductive system. With respect to the direct action, the nature of the organization seems more important than that of the conditions. The effect on offspring may be definite: *e.g.*, size may depend upon the amount of food, color upon quality of food, thickness of skin and hair upon climate, etc. But indefinite variability is a much commoner result of changed conditions, and has probably played a much more important part in the formation of our domestic races. The reproductive system is peculiarly sensitive to very slight external changes. Many plants and animals will not reproduce in domestication, even though individually vigorous; others, though weak and sickly, breed freely. Hence we need not be surprised at the reproductive system acting irregularly and producing variations. But that variation is not exclusively associated with sexual reproduction is demonstrated by the case of plants "sporting" through bud-variations. Such cases, moreover, prove the nature of the organism to be of more importance than the conditions.

Changed habits and use and disuse produce an inherited effect; witness the lighter wing- and heavier leg-bones of the domestic duck, the enlarged udders of milch-cows, or the drooping (unpricked) ears of domestic mammals. Variations are often definitely correlated: short-beaked pigeons have small feet; hairless dogs have imperfect teeth; and blue-eyed white tom-cats are deaf. Hence selection of any one character will probably modify others indirectly. Although the laws governing inheritance are mostly unknown, probably most, if not all, characters tend to be inherited. The popular statement that domestic varieties, when they run wild, revert to the primitive stock is unsupported by satisfactory evidence; and, although reversions occasionally occur in domestication, there is no sign of any general tendency to the loss of acquired characters. Except in being less uniform than natural species, in often differing more widely in some single part, and in being fertile when crossed, there are no well-marked distinctions between our domestic races and the so-called true species of a genus. The many breeds of dogs and cattle may arise from more than one species; but probably those of horses and fowls, and clearly those of rabbits, ducks and pigeons, are each descended from a single species. In this respect the breeds of pigeons are of peculiar importance, since not only carrier and tumbler, runt and barb, pouter and fantail, but at least a score of varieties might be chosen which differ so thoroughly, internally as well as externally, that an ornithologist, treating them as wild birds, would be compelled to grant them specific, and even distinct generic rank. Yet since all these have indisputably arisen from the wild rock-dove (*Columba livia*), it is clear that naturalists who admit a unity to such domestic races, which professed breeders have often laughed to scorn, should in turn be cautious before deriding the unity of wild ones.

How then have domestic races been produced? By external conditions or habits alone? One of their most remarkable features is in exhibiting adaptation, not to their own good, but to man's use or fancy. We know that all the breeds were not produced as perfect as we now see them, and the key is man's power of accumulative selection: nature gives successive variations; man adds them up, making for himself useful breeds. Skilful breeders speak of the organization as plastic and under control, and have effected extensive modifications within our own generation. Unconscious selection, which results from every one trying to possess and breed the best individuals, is even more important. This accumulated change explains why we so often cannot recognize the wild parent stocks of our cultivated plants, while its absence in countries inhabited by uncivilized man explains why these never yield plants worth immediate culture. Man's power of selection is facilitated by keeping large numbers, in which variations are more likely to occur. Facility in preventing crosses is also of importance, as of pigeons as contrasted with cats; some species are, however, less variable than others, *e.g.*, the goose.

Variation under nature

Individual differences arise even in the offspring of the same parents and tend to be inherited; hence they afford material for natural selection to act on and accumulate, precisely as they would for human selection. (Polymorphic genera—*e.g.*, *Rosa, Rubus, Hieracium*, etc.—may perhaps owe their protean character to their variations being of no service or disservice, and consequently not being acted on by natural selection.) In determining whether a form should be ranked as species or variety, the opinion of naturalists of sound judgment and wide experience is the only guide, yet this lacks unanimity (see SPECIES): for example, of the polymorphic genera of the British flora alone Bentham reckons 112 species but Babington 251. Wallace has shown that no certain criterion can possibly be given by which to define his convenient working categories of Malayan *Lepidoptera*, etc., viz., variable forms, local forms, sub-species, and representative species. As De Candolle concluded from his monograph on oaks (in which he shows at least two-thirds of his 300 species to be provisional), "so long as a genus is imperfectly known and its species founded upon a few specimens" they seem clearly limited; but, "just as we come to know them better, intermediate forms flow in and doubts as to specific limits augment." The terms variety and species are thus arbitrarily applied to indefinable groups of more or less closely similar individuals. Common species that range wide and are much diffused are those which vary most. The species of the larger genera in each country vary more frequently than the species of the smaller genera. The species of large genera present strong analogies with varieties, which we can only understand if they originated as such.

Struggle for existence.

The term "struggle for existence" is used in a wide sense, including dependence of one being upon another, and embracing (which is more important), not only the life of the individual, but success in leaving progeny. From the high (geometrical) rate of increase of all organic beings (slow breeders only requiring a few more years to people a whole district) struggle inevitably follows, either one individual with another of the same species, or with the individuals of a distinct species, or with the physical conditions of life. It is the doctrine of Malthus applied with manifold force to the entire animal and vegetable kingdoms, for in this case there can be no artificial increase of food and no prudential restraints from marriage. The checks to increase are most obscure. Eggs or young animals generally suffer most, and plants, mostly as seedlings, both from germinating on ground already occupied and from animals. The amount of food, of course, gives the extreme limit of numbers, very frequently, however, the attacks of enemies, as of game by vermin. Climate plays an important part, and periodical seasons of extreme cold have destroyed as many as four-fifths of the birds of an observed area. Epidemics, too, may occur. In many a species a large stock of individuals is often essential to its preservation. Complex and unexpected checks and relations exist between organic beings which have to struggle together; witness the profound alteration of the flora and fauna of a heath when planted with Scotch fir, these again being wholly dependent upon the exclusion of cattle. But in several parts of the world insects determine the existence of cattle. Again, red clover depends for fertilization upon the humble-bees, these upon immunity from the attacks of field-mice, and thus indirectly upon the numbers of cats; hence no bees, no clover, and the more cats, the more clover! The struggle will almost invariably be most severe between the individuals of the same species, for they frequent the same districts, require the same food, and are exposed to the same dangers. In the case of varieties of the same species the struggle will generally be almost equally severe, and we sometimes see the contest soon decided (as in the case of varieties of wheat or sweet pea, of the mountain-sheep or medicinal leech). Similarly, the struggle between species of the same genus will generally be more severe than between the species of distinct genera, *e.g.*, the replacement of the black rat by the brown or of the large cockroach by the small. The structure of every being is related to that of all the others with which it competes, from which it escapes, or on which it preys; witness alike the teeth and talons of the tiger, or the legs and claws of the parasite clinging to his hair. The albumen of a seedling favors its struggle with plants already growing around it.

Natural selection.

How will this struggle for existence act in regard to variation? Can the principle of selection, so potent in the hands of man, apply under nature? Most efficiently; for, when we bear in mind the constant occurrence of variation, with the strength of the hereditary tendency, also how infinitely close and complex are the mutual relations of organic beings to each other and to their physical conditions of life, and consequently what infinitely varied diversities of structure might be of use to each being under changing conditions of life, can it be thought improbable, seeing that variations useful to man have undoubtedly occurred, that other variations, useful in some way to each being in the great and complex battle of life, should occur in the course of many generations? And, if such do occur, can we doubt (remembering that many more individuals are born than can possibly survive) that individuals having any advantage, however slight, over others would have the best chance of surviving and procreating their kind? On the other hand, we may feel sure that any variation in the least degree injurious would be inevitably destroyed. This preservation of favorable and this destruction of injurious variations are called natural selection, or, less metaphorically, the survival of the fittest. The probable course of natural selection may be understood from the case of a country undergoing change of climate. The proportional numbers of its species will be changed; some will probably become extinct; and these changes will seriously affect the others. Immigration of new forms might occur, with further serious disturbance, or, where this is impossible, we should have places in the economy of nature which might be better filled up. In such cases slight modifications which in any way favored the individuals of any species, by adapting them better to their altered conditions, would tend to be preserved, and natural selection would have free scope for the work of improvement. Moreover, changed conditions increase variability. As man produces a great result, what may not natural selection effect? The former acts only for his own good, nature for that of the being itself; man on mere external characters, nature on the whole machinery of life; man irregularly and imperfectly for a short time, nature by accumulation during whole geological periods. Natural selection is daily and hourly scrutinizing, throughout the world, the slightest variations, rejecting those that are bad, preserving and adding up all that are good, silently and insensibly working, *whenever and wherever opportunity offers*, at the improvement of each organic being in relation to its organic and inorganic conditions of life. It may operate on characters which we are apt to consider of very trifling importance, and its accumulation of small variations may set up unexpected correlative changes. It may modify the egg, seed, or young as easily as the adult, the structure of young to parent and of parent to young, and in social animals it will adapt the structure of each for the benefit of all.[1] The theory of natural selection is next illustrated (1) by supposing the formation of swift varieties of wolves, much as grayhounds have been developed by man; (2) by reference to the excretion of nectar by flowers, its use to insects, the action of these in carrying pollen, its advantage in intercrossing, and the resultant modification and adaptation of flower and insect to each other through the preservation of their advantageous variations. Circumstances favorable for the production of new forms through natural selection are great variability, large numbers of individuals, the complex effects of intercrossing, isolation in confined areas (yet probably still more extension over continental ones, especially if oscillating in level), and considerable lapse of time, although this by itself must not be supposed to do anything (as if the forms of life were undergoing change by some innate law), but merely to afford increased opportunity for variation and environmental change. Extinction, to which rare species are on the way, is caused by natural selection.

Divergence of character.

The divergence of character brought about by artificial selection in domestic breeds is efficiently paralleled in nature, since the more diversified the offspring of each species, the more they will seize on diverse places in the economy of nature, and so increase in numbers. The greatest amount of life can be supported by great diversification of structure. This divergence of character, with extinction of intermediate forms, explains the difficulties of taxonomy, which are then discussed in detail with the aid of a diagram. This, of course, takes the form of a genealogical tree, and suggests that of "the great tree of life, which fills with its dead and broken branches the crust of the earth and covers the surface with its ever-branching and beautiful ramifications."

Natural selection controversy.

The preceding summary of the classical statement of the doctrine of natural selection should be supplemented by reference not only to the original work, to the corroborative labors of its author, and to the able independent treatise (*Natural Selection*) of Wallace, but to the enormous mass of exposition, argument and illustration accumulated by subsequent writers, commencing with Hooker and Asa Gray, Huxley and Haeckel, but soon becoming too numerous even for mention. At the same time the history of the controversy which has arisen out of that statement should also be treated, in so far as it has kept within scientific bounds. The leading objections which have been brought against natural selection, together with the replies to them, should all be summarized, as, for instance, Fleeming Jenkin's important criticism as to the swamping of individual variations by crossing,[2] Mivart's vigorous and detailed polemic against natural selection as capable of accounting for the incipient stages of useful structures, etc.,[3] and so on. But this could not be done to the satisfaction of either party without far exceeding the present limits; happily, however, two chapters of the *Origin of Species* (v. and vi.) are generally admitted to have at least made the attempt up to 1872, the date of the final edition, with great candor and fairness. The various constructive efforts to supplement the hypothesis of natural selection by introducing additional factors of evolutionary change should also be mentioned, headed of course by Darwin's own accessory hypothesis of sexual selection.

Huxley's advocacy.

We must not, however, leave natural selection without a fuller statement of its services and claims, and this may most appropriately be taken from the recent and, as it were, judicial deliverance of their veteran advocate, Prof. Huxley.[4] He first points out the grounds of his agnostic position (up to 1858) with respect to evolution as promulgated by Lamarck, Chambers, and even Spencer: "Firstly, that up to that time the evidence in favor of transmutation was wholly insufficient; and, secondly, no suggestion respecting the causes of the transmutation assumed, which had been made, was in any way adequate to explain the phenomena." He then goes on to say—

---

[1] In the later editions of the *Origin* a brief account of sexual selection is given at this point, *vide infra*, p. 89.

[2] *North British Review*, 1867.

[3] *Genesis of Species*, 1871.

[4] *Life of Darwin*, vol. ii., "On the Reception of the *Origin of Species*."

> "The suggestion that new species may result from the selective action of external conditions upon the variations from their specific type which individuals present—and which we call 'spontaneous' because we are ignorant of their causation—is as wholly unknown to the historian of scientific ideas as it was to biological specialists before 1858. But that suggestion is the central idea of the *Origin of Species*, and contains the quintessence of Darwinism. . . . That which we were looking for, and could not find, was an hypothesis respecting the origin of known organic forms which assumed the operation of no causes but such as could be proved to be actually at work. We wanted, not to pin our faith to that or any other speculation, but to get hold of clear and definite conceptions which could be brought face to face with facts and have their validity tested. The *Origin* provided us with the working hypothesis we sought. . . . The facts of variability, of struggle for existence, of adaptation to conditions were notorious enough, but none of us had suspected that the road to the heart of the species problem lay through them till Darwin and Wallace dispelled the darkness, and the beacon-fire of the *Origin* guided the benighted. . . . The only rational course for those who had no other object than the attainment of truth was to accept 'Darwinism' as a working hypothesis and see what could be made of it. Either it would prove its capacity to elucidate the facts of organic life or it would break down under the strain. . . . Whatever may be the ultimate fate of the particular theory put forward by Darwin, I venture to affirm that, so far as my knowledge goes, all the ingenuity and all the learning of hostile critics have not enabled them to adduce a solitary fact of which it can be said, this is irreconcilable with the Darwinian theory."[1]

Darwin's reasons.

Darwin's own case for natural selection has also been tersely put.[2] "The belief in natural selection must at present be grounded entirely on general considerations,—(1) on its being a *vera causa*, from the struggle for existence and the certain geological fact that species do somehow change; (2) from the analogy of change under domestication by man's selection; (3) and chiefly from this view connecting under an intelligible point of view a host of facts."

Applying to natural selection the accepted tests of a good theory—(1) power of explaining all phenomena and meeting all objections, (2) power of meeting new facts as they occur, (3) applicability as an instrument of research, and (4) power of prediction,—it seems difficult for the most skeptical of critics to avoid ranking it very high, while to those who regard it as triumphantly surviving this assay the "law of parsimony" appears to preclude the necessity of seeking any further explanation of evolution.[3]

Survival of fittest a *vera causa*.

As no serious critic wholly denies the fact of a struggle for existence, nor even a certain preponderance among the survivors in any given area of those best fitted for the struggle, however much he may consider the importance of these facts to have been overstrained in certain directions, we are fairly entitled at the outset to regard natural selection, not only as provisionally superseding earlier attempts at solving the problems of geological and geographical distribution, but as adequately,—it might almost seem finally,—explaining them (see BIOLOGY, DISTRIBUTION). This claim at any rate must be allowed even by those who deny the importance of natural selection as a substantial factor in evolution in the other sub-sciences of physiology and morphology, and this not simply because it was as experts in distribution that Darwin and Wallace themselves arrived at their hypothesis, nor because all subsequent workers in that field of science have adopted it, but because no valid objection, or even supplementary hypothesis, has ever, as regards this important department of science, been so much as proposed. The survival of the fittest, then, is unquestionably a *vera causa*, and one of no small importance in the study of nature (in fact, in undisputed possession of at least one entire field), as also in the study of social life, from which both Darwin and Wallace were directly inspired.[4] The importance of breeding and artificial selection is also undisputed; nor can some small scope for natural selection in the formation of varieties of wild races be denied even by the most grudging of critics who may be versed in the facts of natural history at all. But this amounts to admitting that natural selection, already the undisputed explanation of distributional changes, is at any rate a partial cause in structural and functional ones; while older explanations of these facts, even if not melting into merely abstractional ones, have not succeeded in gaining acceptance.

Uniformitarianism in natural change.

At this point comes in with ponderous weight the conception by which Lyell had for nearly thirty years been preparing the way for Darwin, that of uniformitarianism in natural change. For, although it was perhaps almost as much owing to the unfavorable opinion of Lyell as to the hostility of Cuvier that the doctrine of Lamarck had fallen into such disesteem, and although Lyell himself was accustomed "to keep the name of creation for a natural process which he imagined to be incomprehensible," he was, notwithstanding, as he claimed and as Huxley frankly allows, "strongly disposed to account for the origination of all past and present species of living things by natural causes," and his influence was, therefore, for Huxley, as no doubt for others, "perhaps more potent than any other in keeping alive a sort of pious conviction that evolution after all would turn out true." For, given the principle of Lyell's work,—"the principle that the past must be explained by the present, unless good cause be shown to the contrary, and the fact that, so far as our knowledge of the past history of life on our globe goes, no other cause can be shown,"—it is evident that "consistent uniformitarianism postulates evolution as much in the organic as in the inorganic world. The origin of a new species by other than ordinary agencies would be a vastly greater 'catastrophe' than any of those which Lyell successfully eliminated from geological speculation."

Bearing in mind, then, the lesson of Lyell, that any efficient cause, even though slow or at first sight trifling, can be shown, if acting steadily for vast periods of time, to effect enormous results, the apparent difficulty of adding up varietal differences to specific ones, these to generic, and these again to still larger distinctions, becomes only the inevitable continuation of that summation of individual into varietal differences which no one can deny to be happening around us. Thus the *onus probandi* that species have not arisen in this way comes fairly to be thrown by the advocates of natural selection upon its adversaries. And, as these come individually to realize, through those concrete studies which necessarily underlie all active conviction on one side or the other, the importance of the masses of concrete evidence which have been steadily accumulating, it is little wonder that their majority should not only have so rapidly dwindled, but actually have changed sides so generally as has been the case. Thus, to cite only a single case,—(1) we are now in actual possession of an unbroken and geologically successive series of fossil horses, perfectly gradated through some forty-five "species" back to a five-toed ancestor; (2) we can trace the continued evolution of the existing species in the bones, teeth, and finest peculiarities of the specimens around us, as well as the increasing differentiation of well-marked varieties through artificial selection; (3) we can see that such continuous improvement of skeleton, teeth, etc., as is now and has all along been in progress, must have been profitable to the animals possessing them in the wild state, just as they now are in the tame (since implying better locomotion, digestion, etc.). Hence we soon come to feel a real difficulty in understanding (1) how the continuous summation of small individual advantages through varietal characters into specific, and even generic ones, can be doubted, much less denied, and consequently (2) how the general applicability of the theory of natural selection to interpret the gradual process of historic change can any longer be called in question.

[2] Letter to Bentham, 1863, in *Life of Darwin*, iii. p. 25.

[3] Romanes, *Scientific Evidence of Organic Evolution*, 1886.

[4] Through reading Malthus, *On Population* (see *Origin*, p. 3 *s.q.*). It is worthy of notice also that Herder's early suggestion (*vide supra*) was made in his *Philosophy of History*, Wells's early statement with respect to the races of man, and Patrick Matthew's in a treatise for practical purposes, while an early statement of the doctrine, hitherto apparently overlooked, was made with respect to machines by James Watt (*cf. Catalogue of Industrial Exhibition*, 1851).

Variation along definite lines.

At this point it is right to notice that several evolutionists have suggested or argued for the progress of variation along definite lines; but this return upon pre-Darwinian standpoints has been energetically and, it must be admitted, on the whole as yet successfully combated. Thus Asa Gray (1861–76) has argued for variation along definite and useful lines. Nägeli (1865) regarded the acquisition of certain characters which appear to be of no service to plants as offering a difficulty to natural selection, and as affording a proof of some innate tendency in plants towards perfection, corresponding to what Kölliker entitles the "law of creation." Mivart (1871) has maintained that variations are definite, and frequently sudden and considerable. With such positions must also be noticed the continuous and increasing insistence of Spencer (1852–86) upon environmental action and functional change, although spontaneous variation is not excluded nor considerable importance to natural selection denied. Butler in England, and Cope, Hyatt, and other "Neo-Lamarckians" in America, have more fully developed this reaction, for which experimental evidence has been especially sought in Germany by Semper. And, while Darwin himself long continued an uncompromising opponent of all such heresies, a distinct, though partial, change of opinion was admitted by himself in later years, and has been fully insisted upon both by Mivart and Spencer. While in the *Origin of Species* up to 1869 variations are spoken of as "accidental" (no doubt only in that sense in which a scientific man may fairly use the word), and there is ample proof of Darwin's originally even contemptuous attitude towards Lamarck, and of his substantial rejection of the comparative importance of function or environment in determining variations, these views are unquestionably modified in the well-known peroration to the *Origin of Species*. The further diminishing importance of natural selection is admitted in subsequent editions, as Spencer has pointed out, in the preface to the *Descent of Man*, and indeed elsewhere; while a recent pungent criticism[1] cites evidence of a certain measure of apparently contradictory and indefinite fluctuation of opinion between increased insistence upon use and disuse on the one hand and upon spontaneous variability on the other.

Pleas for indefinite variation.

Since, however, Darwin never developed the grounds of this diminishing reliance upon natural selection, which still remains the central theme of his works, and that upon which their originality, as well as their importance to the theory of evolution, essentially depends (of course as distinguished from their services in summing up the concrete evidence for the fact of evolution and their vast utility in diffusing it), too much weight must not be attached to such isolated expressions of opinion as those referred to above, the more so as these are nowhere borne out by any general change in the tenor of his works. In the absence of any theory of definite and progressive change, and in the presence of multitudinous variations under domestication and in nature which we can neither analyze, rationalize, nor hardly even classify, we are not only justified but logically compelled to regard variation as spontaneous or indefinite, *i.e.*, practically indeterminate in direction, and "therefore unimportant, except as the groundwork for selection to act on." Conversely, variation must be indefinite, else the paramount importance of natural selection must be proportionally impaired as this becomes definite (*cf.* EVOLUTION, vol. viii. p. 657); for we cannot speak of selecting a course from one line of variation, nor even for that matter in the old sense of "variation" at all. Thus, "if it should hereafter be shown that variability is definite and determined in certain directions rather than others" (in short "fated" rather than "spontaneous"), "the importance of natural selection would not be impaired," since it would still have to be regarded as a *vera causa* in the history of species, yet the function ascribed to it would be practically reversed. It would exchange its former supremacy as the supposed determinant among the indefinite possibilities of structure and function for that of simply accelerating, retarding, or terminating the process of otherwise determined change. It would furnish the brake rather than the steam or rails upon the journey of life; or, in other words, instead of guiding the ramifications of the tree of life, it would, in Mivart's phrase, do little more than apply the pruning knife to them.[2] In fact, its functions would be restricted to those of the third Fate, and would no longer, as at present, be supposed to include those of the second. Under these circumstances it is unnecessary to appeal at length to the unanimity with which the later generation of Darwin's exponents (*e.g.*, Lankester, Romanes, Allen, etc.) concur with all preceding ones in the necessary proposition, that "natural selection trusts to the chapter of accidents in the matter of variation." The thesis thus summarized by Lankester thoroughly permeates the *Variation of Animals and Plants under Domestication*, as may be seen from the brief summary of it given below (p.90).[3] Special reference must, however, be made to the important researches of Weismann,[4] since these were devised with the deliberate intention of testing "whether, besides natural selection and the direct action of external conditions, together with the correlative results of these two factors, there might not lie concealed in the organism some other transforming power," such as the "perfecting principle" of Nägeli or the like. The results of these investigations have tended entirely to confirm the theory of natural selection in its classic form; moreover, the same naturalist has since adduced weighty arguments against the transmissibility of individual variations,[5] whether acquired by habit or impressed by environment, and thus proportionally weakened the arguments of Spencer and others in favor of the revival of the Lamarckian factors of change. Variation seems therefore to be driven in more and more upon the reproductive function, and thus an ultra-Darwinian insistence upon the obscure and as yet wholly indefinite factor of variation is strongly forced upon us, and natural selection seems more than ever to be our only possible clue.

Armed, however, with this, we have a consistent means of re-investigation of the whole organic world, in the course of which, not only our existing accumu-

Darwin's biological works.

lations, as of taxonomy and of comparative anatomy, acquire a new interest, and all existing lines of research receive a potent stimulus, but the marvellous variety of adaptation comes into intelligibility and order, — a new teleology thus replacing the old. Of this profound change in the standpoint and interest of modern biology we can form an idea most simply, yet most representatively, by glancing at Darwin's own biological works. Before the *Origin of Species* we have the slow and laborious production of the substantial, yet conventional and comparatively arid, *Zoology of the Beagle* and *Manual of the Cirripedia*, while afterwards the well-known and fascinating new series of zoological and botanical discoveries and generalizations were poured out with remarkable rapidity. The many bold and ingenious applications of the theory of natural selection which we owe to Darwin and his school should here be reviewed seriatim; but it is impossible to do more than mention some of them, *e.g.*, the renascence and development of Sprengel's discovery of the relations of flowers to insects, the elaborate studies on *Fertilization in Orchids*, the *Forms of Flowers*, *Insectivorous Plants*, *Climbing Plants*, *Movement in Plants*, etc. Again, the interpretation of the problems presented by bee and ant society led him to grapple with the problems of mind and language, in the *Descent of Man* and the *Expression of the Emotions;* and the systematic application of the conceptions of biological science to those of psychology, sociology, and ethics, which had been commenced by Comte and continued by Spencer, rapidly passed from its comparative philosophic isolation into wide diffusion through the movement of literature and science.[1]

Application of natural selection to biological science;

This passage from the inductive verification of the theory of natural selection to its deductive application as an engine of research is conspicuously associated with the labors of Haeckel, whose *Generelle Morphologie* (1866) and other minor works have a central historic place amid the first fruit and seed of the new movement in German biology, which was henceforward almost completely Darwinian; and they have equally strong claims to be considered as the starting-point of those logical and unflinching attempts to view all problems in the light of natural selection which have since become more common. By transcending the limits of ordinary biological specialism independently of Darwin, and dispensing with his initial reservation as to the possible creation of primeval forms and with Wallace's final *caveat* as to the origin of man, a thoroughly "monistic" view of biology and its kindred sciences is obtained. The systematic exclusion of the traditional teleology and of that operation of the consciousness of the organism assumed by Lamarck (since indefinite structural variations cannot be associated with, much less developed by, definite psychical ones, and still less by any permanent psychical bias or character) also necessarily follows; and along with this goes the conception of the operation of an extra-organismal mind. The struggle for existence is the sole condition of human progress; and the conception of prevalent or predominant altruism, as systematized by past philosophy and tradition, is thus an alloy of sentimental illusion with baser elements. The doctrine of natural selection is in this way fully developed into a substantially Neo-Lucretian philosophy, and in justice to the logical clearness of the author to whom we especially owe this systematization, it must be admitted that those who grant his postulates, without endorsing his conclusions, have in all cases either refrained from continuing their development or fallen back upon the insertion of some *caveat* or *deus ex machina* at an arbitrary point.

To organic structure and function.

In the same way we have this view of all things in struggle applied to the explanation of the internal structure and function of the organism itself. Once more to quote Huxley,[2] "It is a probable hypothesis that what the world is to organisms in general each organism is to the molecules of which it is composed. Multitudes of these, having diverse tendencies, are competing with one another for opportunity to exist and multiply, and the organism as a whole is as much the product of the molecules which are victorious as the fauna or flora of a country is the product of the victorious organic beings in it." This view has more recently been considerably developed by Roux,[3] and from its logical continuity with the major theory of which it is a corollary is gaining widened acceptance.

With regard to the destructive criticism of the old teleology, which has been led by Haeckel, and aided or acquiesced in by other natural selectionists, it is important to note that the obvious proposition has also repeatedly been urged (*e.g.*, by Huxley and Weismann no less than by their critics, such as Von Hartmann and Lotze), that, just in proportion as our explanation of the origin of organic structures, functions, and adaptations becomes increasingly mechanical, so does an increasingly rigorous teleological view of this mechanism reappear. At most, therefore, we should have exchanged an external and mechanical view of teleology for an (at least relatively) internal and dynamical one.

Sexual selection.

The later hypotheses accessory to natural selection can here be only very briefly outlined. Partly in course of his inquiries into the descent of man, partly also to account for many remarkable phenomena of sexual differentiation in animals (see SEX), Darwin was led to develop the hypothesis of sexual selection which he had already suggested in the *Origin of Species.* Not merely do individuals struggle for existence, but the males struggle for the females; thus the more vigorous tend to obtain mates, and so leave most progeny to repeat the struggle. Special weapons are used in the struggle, both offensive, like the cock's spurs or the stag's horns, and defensive, like the lion's mane; and advantageous variations of these tend to be accumulated. But, as the more beautiful or melodious males appear often to obtain the preference of the females, there is also ground for the conception that the æsthetic advantages frequent in the male sex have similarly been acquired, the more so as we have common experience of how rapidly artificial selection can accumulate superiorities of plumage or song. After the operation of sexual selection has been traced as far as possible through the animal kingdom, the doctrine is applied to man, with the conclusion "that of all the causes which have led to the differences in external appearance between the races of man, and to a certain extent between man and the lower animals, sexual selection had been the most efficient." Acceptance of this hypothesis has been much less general than of natural selection. Criticism has been busy, and this ranges from the serious yet partial dissent of Wallace to fundamental contrast, such as is involved in the theory of the nature and origin of sex suggested in the article SEX, which views the degree of development of the external characters of sex as essentially the outward expression of a proportional stage of the evolution of constitutional "maleness" or "femaleness" (*i.e.*, katabolic and anabolic diathesis respectively).

Physiological selection.

Under the title of "physiological selection" G. J. Romanes has lately proposed "an additional suggestion as to the origin of species," of which the more critical than constructive essence may be briefly given in the author's own words: "As a theory of origin of species natural selection has in its way three cardinal difficulties,—(1) the difference between species and varieties in respect of mutual fertility, (2) the swamping effects of free intercrossing upon an individual variation, (3) the inutility to species of so large a proportion of specific distinctions. . . . Natural selection is not, properly speaking, a theory of the origin of *species:* it is a theory of the origin—or rather of the cumulative development—of *adaptations.* Whenever any variation in the highly variable reproductive system occurs, tending to sterility with the parent form, without entailing fertility with the varietal form, a physiological barrier must interpose, dividing the species into two parts, free to develop distinct histories, without mutual intercrossing, or by independent variation. By regarding mutually sterile species as records of variation in reproductive systems, we are at work, so to speak, on the foundation of the matter."[1]

Laws of Variation.

Origin of variations.

Darwin's theory.

Even those who attach most importance to the doctrine of natural selection as affording a rationale of the process of organic evolution will not seriously dispute that, even were this explanation completely extended to all the details of plant and animal life, another and deeper explanation would still be necessary. That is, the theory of natural selection, being from the external standpoint only—that of the adaptation of the organism to survive the pressures of the environment—would all the more urgently stand in need of a complementary internal explanation, which should elucidate the physiological process of change through which the organism has actually been enabled to adapt itself. As a recent writer tersely expresses it, "The survival of variations is a matter secondary to their origin, and it is becoming realized more and more that this is the point to be explained." How, in short, do we get the variations without which natural selection would have nothing on which to operate? Here we can no longer remain satisfied with the merely general conception of variation as essentially indefinite, with which we have become familiar as the postulate (p. 88) of the theory of natural selection,[2] but must add to it a retrospect of the theories of earlier authors such as has been already outlined,—(*a*) a summary and discussion of the extensive labors of Darwin upon the problems of variation from which this conception of indefiniteness was generalized, followed by (*b*) an account of subsequent progress. Unfortunately the voluminousness of this literature makes such a task practically impossible: instead of the enormous wealth of concrete details accumulated with respect to the *Variation of Animals and Plants under Domestication*, a reference to the volumes under that title must almost suffice. Some acquaintance with this work is, of course, necessary adequately to appreciate the force of its author's general conclusions; these may, however, be briefly outlined from the chapter of the *Origin of Species* (chap. v.) devoted to the laws of variation, and from those (xxii.–xxvi.) of the larger work which contain an ample yet similar discussion.

Environment.

"Our ignorance of the laws of variation is profound. Not in one case out of a hundred can we pretend to assign any reason why this or that part has varied." Changed conditions generally induce mere fluctuating variability in individuals, yet sometimes direct and definite effects upon the mass. The facts and considerations for and against the belief that the conditions of existence act in a potent manner in causing definite modifications of structure are confronted in detail. In some few instances a marked effect has been rapidly produced, *e.g.*, on European men in the United States, European dogs in India, horses in the Falkland Islands, oysters in the Mediterranean, etc. The chemical compounds of some plants and the state of their tissues are readily affected by changed conditions. The production of galls, etc., shows how great changes in structure and color may result from chemical changes. We almost certainly know that organic beings in a state of nature may be modified in various definite ways by the conditions to which they have been long exposed; but it is difficult to distinguish between the definite result of changed conditions and the accumulation through natural selection of indefinite variations which have proved serviceable. But, even granting the utmost weight to conditions, we can rarely see the precise relation between cause and effect. Moreover, many animals and plants of wide range and great diversity of experience yet remain uniform in character. Again, the degree to which domesticated birds, etc., have varied does not stand in any close relation to the amount of change to which they have been subjected. In fact, we may have similar modifications under different conditions, different modifications under similar change of conditions, or no modifications at all. Closely parallel varieties are often produced from distinct races or even species without ascertainable unity of conditions. Bird-variations, too, seem conspicuously independent of circumstances. All these considerations tend to force on our minds the conviction that what we call the external conditions of life are in many cases quite insignificant in comparison with the organization or constitution of the being which varies. No doubt each variation may have its efficient cause, but it is as hopeless to search for the cause of each as to say why a chill or a poison affects one man differently from another. With respect to acclimatization, although habit does something towards the success of the process, yet the appearance of constitutionally different individuals is a far more effective agent.

Use and disuse.

Increased use adds to the size of muscles, together with the bloodvessels, nerves, bony crests of origin, and even the whole bones; it also increases glands and strengthens sense-organs. Increased and intermittent pressure thickens the epidermis; change of food modifies the coats of the stomach and alters the length of the intestine. Disuse weakens and diminishes all parts of the organization,—lungs and chest, wings and their associated bones, etc. Although in domesticated animals this never goes so far that a mere rudiment is left, it seems often to have occurred in nature, the effects of disuse being aided by economy of growth with intercrossing. Changed habits may lead to use or disuse of organs, and consequently to their modification; yet the effects of habit, use and disuse have often been largely combined with the natural selection of innate variations and sometimes overmastered by it.

Correlated variation.

Correlated variation means that the whole organization is so tied together during its growth and development that when slight variations in any part occur, and are accumulated through natural selection, other parts become modified, apparently irrespective of advantage in the change. Variations of structure in the young often effect those of the mature animal; the influence of hard parts, mechanical pressure, the relative position of parts, and the size of the whole body all have important influences. Homologous tissues may exhibit associated variations, *e.g.*, hoofs, hair, and teeth. In most cases the correlation is, however, quite obscure and may seem to be of no utility to the species, as with various monstrosities and diseases. Color may be associated with other constitutional peculiarities. Although correlation is of much importance we may also falsely attribute to it structures which are simply due to inheritance or natural selection, or its effects may be inextricably commingled with those of increased use and of accumulation by natural selection, *e.g.*, the gigantic horns of the Irish elk with the changes necessarily associated with the acquirement of them.

Variability of homologous parts.

Homologous and multiple parts are peculiarly variable, and often tend to cohere. Rudimentary and lowly organized structures are variable. The law of compensation of Goethe and Geoffroy, "that in order to spend on one side nature is forced to economize on the other," holds true to a certain extent with domestic production, but more doubtfully in nature.

Mechanical pressure, etc

Mechanical pressure and relative position of parts seem to be of some importance in determining variations; but such changes are often due to reversion to long-lost characters, which may frequently occur. A part extraordinarily developed in any species tends to be highly variable. Specific characters are more variable than generic characters. Distinct species present analogous variations; but this may arise either from analogous constitution or from reversion Secondary sexual characters are highly variable. "Whatever the cause may be of each slight difference between the offspring and their parents—and a cause for each must exist—we have reason to believe that it is the steady accumulation of beneficial differences which has given rise to all the more important modifications of structure in relation to the habits of each species."

The preceding outline of Darwin's main positions (which are in harmony with his essential doctrine of indefinite variability) prepares us for the discussion of more recent research and opinion. But for our

Results of recent research and opinion.

present concrete knowledge of the influence of environment, use and disuse, including all such researches as those of Semper,[1] or the peculiarly brilliant and luminous investigations of Poulton,[2] the recent valuable summary of Arthur Thompson[3] may conveniently be referred to. The corresponding theoretic argument for the definite causation of most variations by these agencies has been recently re-stated by Spencer,[4] along with his proposed limitation of natural selection. This should be taken along with the testimony of the American Neo-Lamarckian school, among which the learned and suggestive, though too undigested, essays of Cope[5] are especially prominent. The views of Nägeli, Mivart, and other advocates of internal variation here present themselves anew, along with the criticisms and replies to them, as also Weismann's doctrine of variability as being ultimately germinal. But space precludes the survey of this voluminous and unfinished controversy, which, moreover, would not at present yield any general result, since neither the various inductive and deductive arguments, nor the organismal, functional, etc., and environmental explanations which these variously favor, have been as yet exhaustively stated, still less properly confronted, and least of all reconciled, by any author.

Proposed fresh theory of variational laws.

It may be more profitable to attempt, though necessarily in barest outline, a fresh re-examination of the entire field. This may be most appropriately introduced, and the initial conception of the present part of the discussion re-stated, by a passage from Weismann, whose substantial acceptance of the doctrine of natural selection has already been noticed (p. 88). "We certainly cannot remain at the purely empirical conception of variability and heredity as laid down by Darwin in his admirable work. If the theory of selection is to furnish a method of mechanical explanation, it is essential that its factors should be formulated in a precise mechanical sense. But, as soon as we attempt to do this, it is seen that, in the first enthusiasm over the newly discovered principle of selection, the one factor of transformation contained in this principle has been unduly pushed into the background to make way for the other more apparent and better known factors. The first indispensable factor and perhaps the most important in any case, in every transformation is the physical nature of the organism itself." Let us briefly summarize, therefore, the main results of a fresh survey of the leading variations presented by plants and animals, *i.e.*, no longer commencing with the analogy of human selection upon the smallest varietal and specific distinctions, and arguing on Lyell's principle for the cumulative origin of the characters of larger groups, but considering these larger differences from the standpoint of general physiology, without any hypothesis at all.

Preponderance of species maintaining ends over individual struggle and development.

The physiological principle invoked is simply that antithesis between reproductive functions and individual ones which has been familiar since the dawn of physiology, and which, when reduced to its physical terms, is obviously deducible from the principle of conservation of energy. Instead of the generally received doctrine, summarized above, that of indefinite variation, with progress by means of struggle for existence among individuals, its systematic application furnishes a detailed re-interpretation of the forms presented by plants and animals comparable to that afforded by the received hypothesis, but with an essentially altered view of the process and factors of organic evolution as a whole. Briefly stated, the view of evolution thus reached is that of definite variation, with progress essentially through the subordination of individual struggle and development to species-maintaining ends.

Arrest of vegetation by reproduction.

Let us commence with the origin of the flower, which all botanists agree in regarding as a shortened branch. The apparent explanation of natural selection (from two other alternatives, one lengthened, the other unshortened), although morphologically reasonable, is at once excluded by the physiological one of *inevitable* shortening, since the expense of the reproductive functions necessarily checks the vegetative ones, and since we cannot speak of *selection* where the imaginable alternatives are physically impossible. Similarly, the shortening of the inflorescence from raceme to spike or flowerhead, or its hollowing into a fig, with the corresponding reduction in the size of the flowers, receives the same explanation—growth of axis and of appendages checked by reproduction—superseding that current, viz., by mere convenient adaptation to fertilization by insects. The internal structure of the flower is similarly modified, as may be shown in detail in the passage from hypogyny through perigyny to epigyny (these being simply stages of the progressive arrest of the growth of the axis), in the reduction of the floral envelopes and stamens and the number of carpels and ovules, and even in the transition from perispermic to endospermic and finally exalbuminous seeds. But these are the most important of floral variations, and furnish the essentially distinguishing characters of the natural orders; hence, when these are seen, instead of being indefinite, to be parallel and definite (*i.e.*, determined through the continuous checking of vegetation by reproduction along what is thus a single and definite groove of progressive change), the importance of natural selection changes wholly from that of selecting and accumulating supposed indefinite variations to that of retarding definite ones after the stage of maximum utility has been independently reached. The same simple conception unlocks innumerable problems of floral morphology, large and small alike: *e.g.*, it interprets with equal ease the inevitable development of gymnosperm into angiosperm (by continuous subordination of the reproductive carpellary leaf) and the origin of refined minor adaptations, like the splitting fruit of the geranium or the cupped stigma of the pansy, not as achievements of natural selection from among fortuitous variations, but as naturally traceable to the checked vegetation of their respective types of leaf organ, just as in the familiar case of the pinnately-lobed outer sepals of the rose bud. The origin of floral color as primarily an inevitable consequence of the same principle of vegetative subordination through reproductive preponderance was long ago pointed out by Spencer, who unfortunately, however, also accepted without scrutiny the orthodox hypothesis that this incipient floral color would revert to the ordinary green vegetation but for the accident of its attractiveness to insects, and consequently must have owed its accumulation simply to the repeated preservation of the offspring of the accidentally brightest colored; whereas we now see that the arrest of vegetative greenness in the flowers and the exclusive appearance of those coloring matters associated with the imperfect vegetation of spring and autumn are a continuous process of its subordination as a vegetative, and its development as a reproductive, apparatus. Adaptation to insects thus takes a quite secondary place; similiarly with the leafy arrest and floral coloration of bracts; while a detailed examination of thorny plants practically excludes the hypothesis of mammalian selection altogether, and shows spines to arise as an expression of the diminishing vegetativeness—in fact the ebbing vitality—of a shoot or even of an entire species. Evergreens tend to arise in all orders among the forms of more vegetative habit, and in such forms the amount of flowering is usually diminished relatively to the deciduous members of the same group, whilst such constitutional vegetativeness checks the progress of floral evolution. Hence it is that evergreens, and even orders in which they largely occur, are usually less differentiated than their deciduous congeners. The apparently indefinite variations presented by domesticated plants, *e.g.*, the cabbage tribe, are at once classified and interpreted as so many stages along the same course (from leafy kale, through Brussels sprouts with many leaf buds, to cabbage with apical flower bud and finally to cauliflower). The importance of this line of evidence for the Darwinian view of variation and selection becomes still further reduced, although also broadly settled, when we note that, since the subordination of vegetative to reproductive preponderance gave us the origin of ordinal characters, the converse improvement of individual characters at the expense of reproductive ones (on which domestication usually insists and artificial selection depends) can only give us minor ones, for the most part varietal or specific, if so much. The Lyellian analogy for the ultimate accumulation of varietal differences into ordinal characters has thus been misleading. The preceding transition of both organography and physiology from empirical to rational carries with it a similar transition from empirical to rational taxonomy as well; the antagonism of vegetative and reproductive habit is seen to be also general and constitutional. Just as the liliaceous type ranges on one side towards the characteristically vegetative grass or reproductive orchid, so is it with the main variations of every natural alliance, be this order, genus, or even species. Thus the *Ranunculaceæ* have their grassy and their orchid-like types in meadow-rue and larkspur, yet the species of these very genera show examples of the opposite swing of variation; again, the two species or varieties of British oak (*Q. pedunculata* and *Q. sessiliflora*) are thus, so to speak, the incipient grass and orchid forms of their common ancestor (*Q. Robur*). What we call higher or lower species or orders are thus the leaders or the laggards along one or other of these two lines of variation, the representatives of some stage of the predominance on one side or other of that oscillating balance between vegetative and reproductive processes which have long been known as the essential functions of organic life.

Working of the law in animal world.

The results of a similar survey of the animal world, despite the greater intricacy of the problem, are scarcely less definite or comprehensive, and at once lead to a deeper interpretation of the whole. Commencing with an ascending survey, we recognize such essential types of *Protozoa* as the rhizopods, gregarines, and infusors, not as the empirically selected products of spontaneous variation among indefinite possibilities, but simply as the predominatingly amœboid, encysted, and motile phases of the primeval cell-cycle (see Morphology), these three forms of which are fixed by the properties of protoplasm itself (see Sex, vol. xxi. pp. 757–60), each particular phase being fixed by the constitutional bias (diathesis) of its type towards anabolism or katabolism (see Physiology, Protoplasm). This rationale of variation in ultimate terms, *i.e.*, both cellular and protoplasmic, both morphological and physiological, may be continued through all fields, *e.g.*, embryological or pathological, for some diseases are coming to be interpreted as the progressive variation of some function and organ which only disturbs the general balance in its progress towards a new and higher equilibrium.[1] This conception of physiological as well as merely structural life-history rationalizes both animal and vegetable taxonomy. Thus the greatest of all steps in morphological progress, that from the *Protozoa* to the *Metazoa*, is not due to the selection of the more individuated and highly adapted forms, but, to the union of relatively unindividuated cells into an aggregate in which each becomes diminishingly competitive and increasingly subordinated to the social whole. Passing to trifling variations, such as the internal deposition of spicules, we interpret these neither as mere accidents, nor as pure advantages for support or defence, but as arising like plant-crystals or gouty deposits as unremoved waste products, accumulating with local or constitutional passivity. How the inevitable constitutional preponderance of anabolism or katabolism excludes spontaneous variation and subordinates external selection in the formation of types would become clear could we pass in review the animal kingdom, and note how its various alliances all range from passive to more active forms. We should compare the coral or sponge at one end of the scale with the similarly passive (and consequently also skeletal) tortoise and glyptodon at the other. We should read in their anabolic diathesis the secret of accumulating size and of inevitable extinction (nay, even unravel the apparent contradictions with respect to the influence of the environment, as being specially strong upon the passive types, which hence are far richer in species than the corresponding less readily influenced active forms).

Finally, the preponderating importance of the species-maintaining over the individual functions should again be noted in animals as in plants, since the conviction thus becomes inevitable that, in stating the process of evolution essentially in terms of the survival of the fittest in competition, the centre of gravity of the subject has been misplaced. The constant primary insistence upon individual competition for food, and the very subordinate recognition of the inportance of sexual and social co-operation for well-being, which are characteristic of the prevalent theory (witness their proportion in the preceding summary), are traceable at once to the confusion of putting the nutritive factors "in the first place" because they precede the reproductive in time; whereas the organism inevitably enters upon reproduction and so cedes the preponderance—"the first place"—to the other-regarding functions. That increase of reproductive sacrifice which at once makes the mammal and marks its essential stages of further progress (monotreme, marsupial, placental) that increase of parental care, that frequent appearance of sociality and co-operation which even in its rudest forms so surely secures the success of the species attaining it, be it mammal or bird, insect or even worm,—all these phenomena of survival of the truly fittest, through love, sacrifice, and co-operation—need far other prominence than they could possibly receive on the hypothesis of the essential progress of the species through internecine struggle of its individuals at the margin of subsistence. Yet these cases are only the supreme outcomes of that continuous and definite process of variation through individual subordination and species-maintaining preponderance which we have seen modelling even the vegetable world.

In short, while no more denying the existence of competition in nature than the fact of organic progress, we deny the assumed relation of these as cause and effect, and propose an interpretation in essential respects directly converse, without denying the minor agency of use and disuse, environment, etc. Each of the greater steps of progress is definitely associated with an increased measure of subordination of individual competition to reproductive or social ends, and of interspecific competition to co-operative adaptation. The ideal of evolution is thus an Eden; and although competition can never be wholly eliminated, and progress must thus be asymptotic, it is much for our pure natural history to see no longer struggle, but love, as "creation's final law." While ceasing to speak of indefinite variation, we may of course still conveniently retain the rest of the established phraseology, and continue to speak of "natural selection" and of "survival of the fittest," always provided that, in passing from the explanation of the *distributional* survival of individuals or species in contest within a given area to the interpretation of the main line of their morphological and physiological progress, we make the transition from the self-regarding to the other-regarding (in ethical language, from the egoistic to the altruistic) sense of these terms which has above been outlined.[2]

It would be premature to enter upon the extended or deductive application of these considerations, since, pending their acceptance, the preceding statement of the received doctrine of natural selection from spontaneous variations, with all its logical consequences (pp. 89–90), remains valid. Conversely, it is of course obvious that their adoption would involve the extensive modification of the received doctrine, as well as the complementing of new constructive attempts by a re-examination of earlier views of both the process and the philosophy of evolution.[3] (P. GE.)

VARIATIONS, CALCULUS OF. 1. It has been observed (Maxima and Minima, vol. xv. p. 650) that the origin of the calculus of variations may be traced to John Bernoulli's celebrated problem, published in 1696 in the *Acta Eruditorum* of Leipsic, under the following form, *Datis in plano verticali duobus punctis A et B, assignare mobili M viam A M B per quam gravitate sua descendens, et moveri incipiens a puncto A, brevissimo tempore perveniat ad punctum B.* This problem introduced considerations entirely different from those hitherto involved in the discussion of curves, for in its treatment it is necessary to conceive a curve as changing its form in a continuous manner, that is, as undergoing what is styled *deformation.* This change of form can be treated analytically as follows:

---

[1] *Cf.* Sutton, *General Pathology*, London, 1886.

[2] Geddes, "On Variation in Plants," "On the Origin of Thorns and Prickles," and "On the Origin of Evergreens," in *Trans. Bot. Soc. Edin.*, 1886, 1887, 1888.

[3] Geddes, "A Restatement of the Theory of Organic Evolution," *Roy. Soc. Edin.*, 1888.

Suppose $y=f(x)$ to represent the equation of a curve, and let us write $y=f(x)+a\psi(x)$……(1), where a is an infinitesimal quantity, and $\psi(x)$ any function of x subject only to the condition of being finite for all values of x within the limits of the problem. Then equation (1) represents a new curve indefinitely close to the curve $y=f(x)$; and by varying the form of $\psi(x)$ we may regard (1) as representative of any continuous curve indefinitely near to the original curve.

2. Again $a\psi(x)$ is the difference of the y ordinates of the two curves for the same value of x; this indefinitely small difference is called the *variation* of y, and is denoted by δy. It may be regarded as the change in y arising solely from a change in the relation connecting y with x, while x itself remains unaltered. In general, if y be a function of any number of independent variables $x_1, x_2, \dots x_n$, then δy represents any indefinitely small change in y arising solely from a change in the form of the function, while x_1, x_2, etc., are unchanged. Thus the variable y may receive two essentially distinct kinds of increment,—one arising from a change in one or more of the variables, the other arising solely from a change in the relation which connects y with these variables. The former increments are those contemplated and treated of in the ordinary calculus; the latter are those principally considered in the calculus of variations.

We shall follow Strauch, Jellett, Moigno, and the principal modern writers on the subject, by restricting, in general, the symbol δ to the latter species of increment. In many problems both kinds of increment have place simultaneously. Thus, if $y=f(x_1, x_2, x_3)$, and if $\triangle y$ denote the total increment of y, we have

$$\Delta y=\delta y+\frac{df}{dx_1}dx_1+\frac{df}{dx_2}dx_2+\frac{df}{dx_3}dx_3 \text{……………}(2);$$

and so on in all cases.

3. It is readily seen that $\delta\frac{dy}{dx}=\frac{d}{dx}\delta y$, and in general that $\delta\frac{d^ny}{dx^n}=\frac{d^n}{dx^n}\delta y$. The last equation may be written

$$\delta D^ny=D^n\delta y \text{……………………}(3),$$

where D stands for the symbol of differentiation, $\frac{d}{dx}$.

4. We shall adopt Newton's notation and write $\dot{y}$ for $\frac{dy}{dx}$, $\ddot{y}$ for $\frac{d^2y}{dx^2}$, $y^{(n)}$ for $\frac{d^ny}{dx^n}$, and proceed to consider the variation of the general expression $V=f(x, y, \dot{y}, \ddot{y}, \dots y^{(n)})$, in which the form of the function f is given, while that of y in terms of x is indeterminate. Here, considering x as unchanged, we have

$$\delta V=\frac{dV}{dy}\delta y+\frac{dV}{d\dot{y}}\delta\dot{y}+\dots+\frac{dV}{dy^{(n)}}\delta y^{(n)}.$$

Now let $\frac{dV}{dy}=P$, $\frac{dV}{d\dot{y}}=P_1, \dots \frac{dV}{dy^{(n)}}=P_n$,

then we have

$$\delta V=P\delta y+P_1D\delta y+P_2D^2\delta y+\dots+P_nD^n\delta y \text{…………}(4).$$

5. Next let us consider the variation of the definite integral $U=\int_{x_0}^{x_1}Vdx$, where V does not contain either of the limits x_0 and x_1. Here, when the limits are unchanged, we have $\delta U=\int_{x_0}^{x_1}\delta Vdx$, and, when the limits undergo change,

$$\delta U=\delta\int_{x_0}^{x_1}Vdx=\int_{x_0}^{x_1}\delta Vdx+V_1dx_1-V_0dx_0 \text{………}(5).$$

6. We shall here bring in a new symbol, called the *sign of substitution,* which was introduced by Sarrus.[1] Thus, if F be any function of x, y, etc., the result of substituting x_1 for x in F—the other variables being unchanged—is represented by $\Big/^{x_1}F$ in the form of notation adopted by Moigno and Lindelöf.[2] The difference between $\Big/^{x_1}F$ and $\Big/^{x_0}F$ is represented by $\Big/_{x_0}^{x_1}F$. Employing this notation, (5) is written

$$\delta U=\int_{x_0}^{x_1}\delta Vdx+\Big/_{x_0}^{x_1}Vdx \text{……………}(6).$$

7. We now proceed to transform the last equation, commencing with the case in which V is a function of x, y, and $\dot{y}$ solely. Here

$$\delta U=\int_{x_0}^{x_1}(P\delta y+P_1D\delta y)dx+\Big/_{x_0}^{x_1}Vdx,$$

$$=\int_{x_0}^{x_1}\left(P-\frac{dP_1}{dx}\right)\delta ydx+\Big/_{x_0}^{x_1}P_1\delta y+\Big/_{x_0}^{x_1}Vdx \text{…………}(7).$$

Next let V be a function of x, y, $\dot{y}$, and $\ddot{y}$, then

$$\delta U=\int_{x_0}^{x_1}(P\delta y+P_1D\delta y+P_2D^2\delta y)dx+\Big/_{x_0}^{x_1}Vdx.$$

Hence, observing that

$$\frac{d}{dx}\left(\frac{dP_2}{dx}\delta y-P_2\frac{d\delta y}{dx}\right)=\frac{d^2P_2}{dx^2}\delta y-P_2\frac{d^2\delta y}{dx^2},$$

we get

$$\delta U=\int_{x_0}^{x_1}\left(P-\frac{dP_1}{dx}+\frac{d^2P_2}{dx^2}\right)\delta ydx+\Big/_{x_0}^{x_1}Vdx$$
$$+\Big/_{x_0}^{x_1}\left(P-\frac{dP_2}{dx}\right)\delta y+\Big/_{x_0}^{x_1}P_2\delta\dot{y} \text{……………………}(8).$$

In general, if V be a function of $x, y, \dot{y}, y, \dots y^{(n)}$, we have

$$\delta U=\int_{x_0}^{x_1}(P\delta y+P_1D\delta y+\dots+P_nD^n\delta y)\,dx+\Big/_{x_0}^{x_1}Vdx.$$

Now let D_1 denote the differentiation of δy, and D_2 the differentiation of P_1, P_2, etc.; we may write

$$P_mD^m\delta y-(-1)^m\delta yD^mP_m=(D_1^m-(-1)^mD_2^m\,.\,P_m\delta y$$
$$=(D_1+D_2)(D_1^{m-1}-D_1^{m-2}D_2+\dots\pm D_2^{m-1})P_m\delta y$$
$$=\frac{d}{dx}\left(P_mD^{m-1}\delta y-\frac{dP_m}{dx}D^{m-2}\delta y+\dots+(-1)^{m-1}\delta y\frac{d^{m-1}P_m}{dx^{m-1}}\right).$$

Hence

$$\int_{x_0}^{x_1}P_mD^m\delta ydx=(-1)^m\int_{x_0}^{x_1}\frac{d^mP_m}{dx^m}\delta ydx$$
$$+\Big/_{x_0}^{x_1}\left(P_mD^{m-1}\delta y-\frac{dP_m}{dx}D^{m-2}\delta y+\dots+(-1)^{m-1}\delta y\frac{d^{m-1}P_m}{dx^{m-1}}\right).$$

Applying this to the different terms in the value of δU given above, we get

$$\delta U=\int_{x_0}^{x_1}\left(P-\frac{dP_1}{dx}+\frac{d^2P_2}{dx^2}-\dots+(-1)^n\frac{d^nP_n}{dx^n}\right)\delta ydx$$
$$+\Big/_{x_0}^{x_1}\left(P_1-\frac{dP_2}{dx}+\dots+(-1)^{n-1}\frac{d^{n-1}P_n}{dx^{n-1}}\right)\delta y$$
$$+\Big/_{x_0}^{x_1}\left(P_2-\frac{dP_3}{dx}+\dots+(-1)^{n-2}\frac{d^{n-2}P_n}{dx^{n-2}}\right)\frac{d\delta y}{dx}$$
$$\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot$$
$$+\Big/_{x_0}^{x_1}P_n\frac{d^{n-1}\delta y}{dx^{n-1}}+\Big/_{x_0}^{x_1}Vdx \text{……………………}(9).$$

This result may be written

$$\delta U=\int_{x_0}^{x_1}(P)\delta ydx+\Big/_{x_0}^{x_1}Vdx$$
$$+\Big/_{x_0}^{x_1}\{(P_1)\delta y+(P_2)\delta\dot{y}+\dots+(P_n)\delta y^{(n-1)}\} \text{……}(10).$$

where $(P)=P-\frac{dP_1}{dx}+\frac{d^2P_2}{dx^2}-\dots$, $(P_1)=P_1-\frac{dP_2}{dx}+\frac{d^2P_3}{dx^2}-\dots$, and so on.

8. This expression consists of three parts,—(1) the definite integral $\int_{x_0}^{x_1}(P)\delta ydx$, which depends on δy, the change in the form of the function y; (2) the expression $\Big/_{x_0}^{x_1}Vdx$, which depends solely on the change in the limiting values of x; and (3) the quantity $\Big/_{x_0}^{x_1}\{(P_1)\delta y+(P_2)\delta\dot{y}+\dots\}$, which depends on the variations of y, $\dot{y}$, etc., at the limits. It is often convenient to write (10) in the abbreviated form

$$\delta U=L+\int_{x_0}^{x_1}M\delta ydx \text{……………………}(11).$$

---

[1] *Recherches sur le Calcul des Variations*, 1848.

[2] *Calc. des Var.*, 1861.

9. The principal applications of the calculus of variations have reference to the determination of the form of one or more unknown functions contained in a definite integral, in such a manner that the integral shall have a maximum or minimum value. For instance, to determine the form of the function y which renders $U = \int_{x_0}^{x_1} V dx$ a maximum or a minimum, we have as above $\delta U = L + \int_{x_0}^{x_1} M \delta y dx$. Here, as in the differential calculus (see INFINITESIMAL CALCULUS, § 64), for a maximum or minimum value of U it is readily seen that we must have $\delta U = 0$; this leads to $L = 0$ and $\int_{x_0}^{x_1} M \delta y dx = 0$. Now the latter integral cannot be zero for all indefinitely small values of δy unless $M = 0$ for all values within the limits of integration. Hence we get the differential equation in y,

$$P - \frac{dP_1}{dx} + \frac{d^2 P_2}{dx^2} - \ldots + (-1)^n \frac{d^n P_n}{dx^n} = 0 \ \ldots\ldots(12).$$

10. We here suppose that there is no restriction on δy, so that for any value of x the increments $+\delta y$ and $-\delta y$ are equally compatible with the conditions of the problem. The reasoning consequently will not apply if the conditions render this impossible. For instance, if a curve be restricted to lie within a given boundary, then for all points on the boundary the displacements must be inwards, and the opposite displacements are impossible. In this case[1] the curve satisfying a required maximum or minimum condition consists partly of portions of the boundary and partly of portions of a curve satisfying the equation $M = 0$.

11. The equation $M = 0$ is in general a differential equation of the degree $2n$; accordingly its solution usually contains $2n$ arbitrary constants. The values of these constants are to be determined by aid of the equations deduced from $L = 0$ in combination with the given conditions at the limits. For example, if V be a function of x, y, and $\dot{y}$ solely, the solution of $P - \frac{dP_1}{dx} = 0$ is in general of the form $y = f(x, c_1, c_2)$. Now, suppose that the limiting points are restricted to the curves $y_0 = f_0(x_0)$ and $y_1 = f_1(x_1)$, then we get at the limits $\delta y_0 + \dot{y}_0 dx_0 = f_0'(x_0) dx_0$ and $\delta y_1 + \dot{y}_1 dx_1 = f_1'(x_1) dx_1$. Hence, substituting in $L = 0$ the values of δy_0 and δy_1 derived from these equations, we get, since dx_0 and dx_1 are arbitrary,

$$\left. \begin{array}{l} V_0 + (P_1)_0 (f_0'(x_0) - \dot{y}_0) = 0 \\ V_1 + (P_1)_1 (f_1'(x_1) - \dot{y}_1) = 0 \end{array} \right\} \ldots\ldots\ldots\ldots\ldots\ldots(13).$$

We have therefore six equations for the determination of the six quantities x_0, y_0, x_1, y_1, c_1, and c_2.

The integration of the equation $M = 0$ is much simplified in particular cases.

(1) Let V be a function of x and $\dot{y}$ solely, then we have $\frac{dP_1}{dx} = 0$, therefore

$$P_1 = c \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(14).$$

(2) If V be a function of y and $\dot{y}$ solely, $P = \frac{dP_1}{dx}$, also $\frac{d}{dx}(V) = P\dot{y} + P_1\ddot{y} = \frac{dP_1}{dx}\dot{y} + P_1\ddot{y}$. Hence, integrating, we get

$$V = P_1 \dot{y} + c \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(15),$$

where c is an arbitrary constant.

12. For example, let us consider Bernoulli's problem of the curve of quickest descent under the action of gravity. Take the axis of x vertical and that of y horizontal, and suppose the particle to start from the point x_0, y_0, with the velocity due to the height h; then, if v be the velocity at any point, we have $v^2 = 2g(x + h - x_0)$, also $dt = \frac{ds}{v} = \frac{\sqrt{1 + \dot{y}^2} dx}{\sqrt{2g}\sqrt{x + h - x_0}}$. Here, neglecting a constant factor, we may write $U = \int_{x_0}^{x_1} \frac{\sqrt{1 + \dot{y}^2} dx}{\sqrt{x + h - x_0}}$; and by (14) we get $\frac{\dot{y}}{\sqrt{1 + \dot{y}^2}} = c\sqrt{x + h - x_0}$. Now, writing a for $1/c^2$ and assuming $x + h - x_0 = a \sin^2\theta$, we find $dy = \tan\theta dx = a(1 - \cos 2\theta) d\theta$; therefore $y = a(\theta - \sin\theta \cos\theta) + K$, and we infer that the curve is a cycloid.

(α) If we suppose the upper limit to be fixed and the lower restricted to the curve $y_1 = f_1(x_1)$, we get from (13)

$$1 + \tan\theta_1 f_1'(x_1) = 0 \ldots\ldots\ldots\ldots\ldots\ldots(16);$$

accordingly the curve intersects the bounding curve orthogonally. (β) Next let the upper limit be restricted to the curve $y_0 = f_0(x_0)$; then since V contains x_0, we have an additional term in δU arising from the change in x_0, viz., $dx_0 \int_{x_0}^{x_1} \frac{dV}{dx_0} dx$; consequently the coefficient of dx_0 in δU is $\int_{x_0}^{x_1} \frac{dV}{dx_0} dx - \{ V_0 + (P_1)_0 (f_1'(x_0) - \dot{y}_0) \}$,

and we have $$\int_{x_0}^{x_1} \frac{dV}{dx_0} dx = V_0 + (P_1)_0 (f_0'(x_0) - \dot{y}_0) \ldots\ldots(17).$$

If we substitute for V its value, we get without difficulty from this equation $1 + \tan\theta_1 f_0'(x_0) = 0$. Comparing this with (16), we see that the tangents to the bounding curves at the extremities of the trajectory are parallel (Moigno, *op. cit.*, p. 230).

13. More generally, consider the curve for which $U = \int_{x_0}^{x_1} \mu ds = \int_{x_0}^{x_1} \mu \sqrt{1 + \dot{y}^2} dx$ is a maximum or a minimum, where μ is a given function of x and y. Here $P = \frac{d\mu}{dy}\sqrt{1 + \dot{y}^2}$, $P_1 = \frac{\mu\dot{y}}{\sqrt{1 + y^2}}$, and we get $\frac{d\mu}{dy}\sqrt{1 + \dot{y}^2} = \frac{\dot{y}}{\sqrt{1 + \dot{y}^2}}\left(\frac{d\mu}{dx} + \dot{y}\frac{d\mu}{dy}\right) + \mu\frac{d}{dx}\left(\frac{\dot{y}}{\sqrt{1 + \dot{y}^2}}\right)$; hence, if ρ be the radius of curvature, we have

$$\frac{1}{\rho} = -\frac{1}{\mu}\left(\cos\alpha\frac{d\mu}{dx} + \cos\beta\frac{d\mu}{dy}\right) \ldots\ldots\ldots\ldots\ldots\ldots(18).$$

where α, β are the angles which the normal makes with the co-ordinate axes respectively. Jellett remarks[2] that, if the proposed integral had been $\int\frac{ds}{\mu}$, we should then have arrived at the equation $\frac{1}{\rho} = \frac{1}{\mu}\left(\cos\alpha\frac{d\mu}{dx} + \cos\beta\frac{d\mu}{dy}\right)$, and consequently have seen that the two curves contained under the equation $\rho^2 = f(x, y, \dot{y})$ are such that, if one renders $\int\mu ds$ a maximum or a minimum, the other possesses the same property with regard to $\int\frac{ds}{\mu}$.

14. Next, to find the curve such that the surface generated by its revolution round a given line shall be a minimum. Here, neglecting a constant multiplier, we may write $U = \int_{x_0}^{x_1} y\sqrt{1 + \dot{y}^2} dx$; accordingly by (15) we have $y = c\sqrt{1 + \dot{y}^2}$. This gives $\frac{dy}{\sqrt{y^2 - c^2}} = \frac{dx}{c}$; and hence

$$\frac{x + b}{c} = \log\left(\frac{y + \sqrt{y^2 - c^2}}{c}\right),$$

or $$y = \frac{c}{2}\left(e^{(x + b)/c} + e^{-(x + b)/c}\right) \ldots\ldots\ldots\ldots(19),$$

which represents the common catenary.

15. We now proceed to generalize the results in § 11. If V be a function of x, $\dot{y}$, $\ddot{y}$, $\ldots y^{(n)}$, not containing y explicitly, we have by integration

$$P_1 - \frac{dP_2}{dx} + \frac{d^2 P_3}{dx^2} - \ldots + (-1)^{n-1}\frac{d^{n-1} P_n}{dx^{n-1}} = c \ (20),$$

where c is an arbitrary constant. Again, if V does not contain x explicitly, $\frac{d}{dx}(V) = \dot{y}P + \ddot{y}P_1 + \ldots + y^{(n+1)}P_n$. Also, from the equation $M = 0$ we see that $P = \frac{dP_1}{dx} - \frac{d^2 P_2}{dx^2} + \ldots - (-1)^n\frac{d^n P_n}{dx^n}$; hence $\frac{d}{dx}(V) = \ddot{y}P_1 + \dot{y}\frac{dP_1}{dx}$

$$+ \dddot{y}P_2 - \dot{y}\frac{d^2 P_2}{dx^2} + \ldots + y^{(n+1)}P_n - (-1)^n\dot{y}\frac{d^n P_n}{dx^n}$$
$$= (D_1 + D_2)(\dot{y}P_1) + (D_1^2 - D_2^2)(\dot{y}P_2) + \ldots$$
$$+ (D_1^n - (-1)^n D_2^n)(\dot{y}P_n),$$

where D_1 represents the differentiation of $\dot{y}$, $\ddot{y}$, etc., and D_2 that of P_1, P_2, etc. Consequently, by integration

$$V = c + \dot{y}(P_1) + \ddot{y}(P_2) + \ldots + y^{(n)}P_n \ \ldots\ldots\ldots(21),$$

a differential equation of the order $2n - 2$ at the highest. Again, if V contains neither x nor y explicitly, we may substitute c' for (P_1), and consequently we have

$$V = c + c'\dot{y} + \ddot{y}(P_2) + \ldots + y^{(n)}P_n \ \ldots\ldots\ldots(22).$$

16 As an example, let us investigate the curve for which the area between the curve, its evolute, and the extreme radii of curvature shall be a minimum. Here $U = \int_{s_0}^{s_1} \rho ds$

---

[1] For a full discussion of such cases, see Todhunter, *on the Calculus of Variations*, 1871 (Adams prize essay), Cambridge.

[2] *Calculus of Variations*, p. 140.

$=\int_{x_0}^{x_1}\frac{(1+\dot{y}^2)^2}{\ddot{y}}dx$. Hence by (22), since $\ddot{y}P_2=-V$, we have $V=c_1+c_2\dot{y}$, or $\rho=\frac{c_1}{\sqrt{1+\dot{y}^2}}+\frac{c_2\dot{y}}{\sqrt{1+\dot{y}^2}}$; therefore $\frac{ds}{d\phi}=c_1\cos\phi+c_2\sin\phi$, where ϕ is the angle made by the tangent with the axis of x. This leads to

$$s=-c_1\sin\phi+c_2\cos\phi+c_3 \text{..............} (23),$$

which shows that the curve is a cycloid. Again, (1) if the extreme points be fixed, the equations at the limits are $(P_2)_0=0$, $(P_2)_1=0$. This shows that the radius of curvature vanishes at both limits and the curve must be a complete cycloid. (2) If the extremities lie on the curves $y_0=f_0(x_0)$, $y_1=f_1(x_1)$; then the equations furnished by $L=0$ are

$$\left.\begin{aligned} V_0+(P_1)_0\{f_0'(x_0)-\dot{y}_0\}=0,\quad (P_2)_0=0 \\ V_1+(P_1)_1\{f_1'(x_1)-\dot{y}_1\}=0,\quad (P_2)_1=0 \end{aligned}\right\} \text{......} (24).$$

Hence the extreme points are cusps on the cycloid; moreover, since in this case $V_0=0$ and $V_1=0$, we have $\dot{y}_0-f_0'(x_0)=0$, $\dot{y}_1-f_1'(x_1)=0$, which show that the cycloid at each of its extremities touches these curves, and that the line joining the extreme points is normal to each of the bounding curves.

It is easily seen that the minimum area is four times that of the circle which generates the cycloid.

17. Next let us consider the variation of $U=\int_{x_0}^{x_1}Vdx$, where V is a given function of $x, y, z, \dot{y}, \dot{z}, \ddot{y}, \ddot{z}, \dots y^{(n)}, z^{(m)}$, and y, z are undetermined functions of x.

Let $$Q=\frac{dV}{dz},\ Q_1=\frac{dV}{d\dot{z}}, \text{ etc.,}$$

then $$\delta U=\Big|_{x_0}^{x_1}Vdx+\int_{x_0}^{x_1}(P\delta y+P_1D\delta y+\dots+P_nD^n\delta y)\,dx$$
$$+\int_{x_0}^{x_1}(Q\delta z+Q_1D\delta z+\dots+Q_mD^m\delta z)\,dx.$$

Proceeding as in § 7, we find

$$\delta U=\int_{x_0}^{x_1}(P)\delta y dx+\int_{x_0}^{x_1}(Q)\delta z dx+\Big|_{x_0}^{x_1}Vdx$$
$$+\Big|_{x_0}^{x_1}\{(P_1)\delta y+(P_2)\delta\dot{y}+\dots+P_n\delta y^{(n-1)}\}$$
$$+\Big|_{x_0}^{x_1}\{(Q_1)\delta z+(Q_2)\delta\dot{z}+\dots+Q_m\delta z^{(m-1)}\}\ (25),$$

where (P), (P_1), ... have the same meaning as in § 7, and (Q), (Q_1), ... are the corresponding functions for the variable z.

18. The determination of y and z where $\int_{x_0}^{x_1}Vdx$ is a maximum or a minimum leads, as in § 8, to the equations $(P)=0$, $(Q)=0$, along with the equation at the limits

$$\Big|_{x_0}^{x_1}Vdx+\Big|_{x_0}^{x_1}\{(P_1)\delta y+\dots P_n\delta y^{(n-1)}\}+\Big|_{x_0}^{x_1}\{(Q_1)\delta z$$
$$+\dots Q_m\delta z^{(m-1)}\}=0.$$

The mode of treatment is similar to that for a single dependent variable.

19. In the discussion of a curve which possesses a maximum or minimum property, if we limit the investigation to all curves of a given length or which satisfy some other condition, we have a distinct class of problems, which originated in the isoperimetrical problems of James Bernoulli. They were originally styled *isoperimetrical*, but are now called problems of *relative maxima and minima*. Thus, let it be proposed to determine the form of y which renders $U=\int_{x_0}^{x_1}Vdx$ a maximum or a minimum, and which also satisfies the condition $U'=\int_{x_0}^{x_1}V'dx=$ constant, where V and V' are given functions of x, y, $\dot{y}$, etc. It is obvious that, if U is a maximum or a minimum, so also is $U+aU'$, where a is any arbitrary constant. Accordingly the problem reduces to the determination of the maximum or minimum value of the integral $\int_{x_0}^{x_1}(V+aV')dx$, regarding a as a constant, whose value is to be determined by aid of the given value of U'.

20. Another class of problems closely allied to the preceding is that in which the variables are connected by one or more equations of condition: for instance, when y, $\dot{y}$, $\ddot{y}$, etc., z, $\dot{z}$, etc., are connected by a relation $W=0$, we investigate the maximum or minimum values of

$$U=\int_{x_0}^{x_1}(V+\lambda W)dx \text{.................} (26),$$

where λ is an indeterminate function of x. We will illustrate these principles by examples.

21. To find the curve connecting two fixed points such that the surface generated by its revolution round a fixed line shall be given, and the volume of the generated solid shall be a maximum. Taking the fixed line as the axis of x, we may write $U=\int_{x^0}^{x_1}(y^2+ay\sqrt{1+\dot{y}^2})dx$.

Hence by (15) we have $y^2+ay\sqrt{1+\dot{y}^2}=c+\frac{ay\dot{y}^2}{\sqrt{1+\dot{y}^2}}$,

or $$y^2+\frac{ay}{\sqrt{1+\dot{y}^2}}=c \text{.........................} (27).$$

If the curve meets the fixed axis we have $c=0$, and the curve is a circle whose centre lies on the axis.

The further integration of (27) depends on elliptic functions; it can, however, be shown without difficulty, as was proved by Delauney, that the curve is that generated by the focus of an ellipse or hyperbola which rolls on a fixed right line.

22. As an illustration of the method of § 20 we shall consider again the problem of § 13, taking the arc for independent variable. Let $\dot{x}=\frac{dx}{ds}$, $\dot{y}=\frac{dy}{ds}$, then we have the relation $\dot{x}^2+\dot{y}^2-1=0$; and we write $U=\int_{s_0}^{s_1}\{\mu+\frac{1}{2}\lambda(\dot{x}^2+\dot{y}^2-1)\}ds=\int_{s_0}^{s_1}Vds$, where $V=\mu+\frac{1}{2}\lambda(\dot{x}^2+\dot{y}^2-1)$.

Hence for a maximum or minimum we have

$$\frac{d\mu}{dx}=\frac{d}{ds}(\lambda\dot{x}),\quad \frac{d\mu}{dy}=\frac{d}{ds}(\lambda\dot{y}) \text{..............} (28);$$

therefore $$\frac{d\mu}{ds}=\dot{x}\frac{d\mu}{dx}+\dot{y}\frac{d\mu}{dy}=\frac{d\lambda}{ds},$$

or $$\mu=\lambda+c \text{..............................} (29).$$

Again, the equation at the limits is

$$\Big|_{s_0}^{s_1}\mu ds+\Big|_{s_0}^{s_1}\lambda(\dot{x}\delta x+\dot{y}\delta y)=0 \text{.............} (30);$$

also at each limit we have $dx=\delta x+\dot{x}ds$, $dy=\delta y+\dot{y}ds$; hence (30) transforms into $\Big|_{s_0}^{s_1}(\mu-\lambda)ds+\Big|_{s_0}^{s_1}\lambda(\dot{x}dz+\dot{y}dy)=0$,

or $$cd(s_1-s_0)+\Big|_{s_0}^{s_1}\lambda(\dot{x}dx+\dot{y}dy)=0 \text{...........} (31).$$

Now if the length of the curve be given, the first term in (31) vanishes; whereas, if the length be not given, we must have $c=0$. Consequently in the isoperimetrical problem we have $\mu=\lambda+c$, and in the general case $\lambda=\mu$. If we substitute μ for λ in (28) we can readily deduce the results already given in § 13.

23. More generally, let μ be a function of x, y, $\dot{x}$ and $\dot{y}$, then we have $V=\mu+\frac{1}{2}\lambda(\dot{x}^2+\dot{y}^2-1)$. Here we readily deduce

$$V=c+\dot{x}\frac{dV}{d\dot{x}}+\dot{y}\frac{dV}{d\dot{y}} \text{.................} (32);$$

and the equation at the limits becomes

$$cd(s_1-s_0)+\Big|_{s_0}^{s_1}\left(\frac{dV}{d\dot{x}}dx+\frac{dV}{d\dot{y}}dy\right)=0.$$

This shows, as before, that when the length of the curve is not given we have $c=0$.

24. The criterion for distinguishing between maximum and minimum solutions was investigated by Legendre, Lagrange, and other eminent mathematicians, for whose contributions to the solution of this problem, see Todhunter's *History of the Calculus of Variations.* The full analytical investigation was, however, first given by Jacobi, of whose results we here give a brief discussion.

In this investigation, as in ordinary problems of maxima and minima, it is necessary to take into consideration the squares and the higher powers of our indefinitely small variations. Thus, if $U=\int_{x_0}^{x_1}Vdx$, the complete variation of U may be written $\delta U+\frac{1}{2}\delta^2U+$ etc., where δU depends on the first powers of δy, $\delta\dot{y}$, etc., and δ^2U on their second powers, etc. Again, we will suppose that the limiting values of y and of its first $n-1$ differential coefficients are fixed, then $\delta U = \int_{x_0}^{x_1} \delta V dx = \int_{x_0}^{x_1} M\delta y dx$, and $\delta^2 U = \int_{x_0}^{x_1} \delta M \delta y dx$. The solutions of the problem, as already observed (§ 8), are given by the equation $M = 0$. Also for a true maximum it is necessary that $\delta^2 U$ should be constantly negative, and for a minimum that it should be positive. If $\delta^2 U = 0$, or if it change its sign between the limits of integration, the result is in general neither a maximum nor a minimum. As before, we suppose V a function of $x, y, \dot{y} \ldots y^{(n)}$, and

$$M = P - \frac{dP_1}{dx} + \frac{d^2 P_2}{dx^2} - \ldots + (-1)^n \frac{d^n P_n}{dx^n}$$

$$= \left(\frac{d}{dy} - D\frac{d}{d\dot{y}} + D^2 \frac{d}{d\ddot{y}} - \ldots\right) V;$$

therefore $\delta M = \left(\frac{d}{dy} - D\frac{d}{d\dot{y}} + D^2 \frac{d}{d\ddot{y}} - \ldots\right)\delta V$

$$= \left(\frac{d}{dy} - D\frac{d}{d\dot{y}} + D^2 \frac{d}{d\ddot{y}} - \ldots\right)$$
$$\left(\frac{dV}{dy} + \frac{dV}{d\dot{y}}D + \ldots + \frac{dV}{dy^{(n)}}D^n\right)\delta y \quad (33).$$

When this is developed, we see that every term, disregarding sign, is of the form $D^l \frac{d^2 V}{dy(l)\, dy(m)} D^m \delta y$. Also, if we combine this with the corresponding term, and make $l = m + r$, we readily see that

$$\delta M = \Sigma (-1^l) D^m \left\{ D^r \frac{d^2 V}{dy(l)\, dy(m)} + (-1)^r \frac{d^2 V}{dy(l)\, dy(m)} D^r \right\}$$
$$D^m \delta y \quad (34).$$

Hence δM is reducible to the form

$$\delta M = (A_0 + DA_1 D + D^2 A_2 D^2 + \ldots + D^n A_n D^n)\delta y \ldots (35),$$

provided it can be shown that $D^r u + (-1)^r u D^r$ is reducible to an operation of such a form. Now this is readily seen, for $Du - uD \equiv \dot{u}$, therefore $D^2 u - DuD \equiv D\dot{u}$ and $DuD - uD^2 \equiv \dot{u}D$; consequently $D^2 u + uD^2 \equiv 2DuD + \ddot{u}$. In like manner $D^3 u - uD^3 \equiv 2DuD + \dddot{u}$, and the proposed result can be readily shown by induction. Hence we infer that we may write δM in the form (35).

25. We have in the next place to show that the *symbolic operator* $u(A_0 + DA_1 D + \ldots + D^n A_n D^n)u$ may be written in the form $B_0 + DB_1 D + \ldots + D^n B_n D^n$. To establish this, it is sufficient to show that $uD^r A_r D^r u$ can be transformed into the shape in question. By Leibnitz's theorem we have

$$D^r u \equiv uD^r + r\dot{u}D^{r-1} + \frac{r(r-1)}{1\,.\,2}\ddot{u}D^{r-2} + \ldots$$

and $$uD^r \equiv D^r u - rD^{r-1}\dot{u} + \frac{r(r-1)}{1\,.\,2}D^{r-2}\ddot{u} - \ldots$$

But these may be written

$$D^r u \equiv uD^r + L_1 D^{r-1} + L_2 D^{r-2} + \ldots + L_r,$$
$$uD^r \equiv D^r u - D^{r-1} L_1 + D^{r-2} L_2 - \ldots,$$

therefore $uD^r A_r D^r u \equiv (D^r u - D^{r-1} L_1 + \ldots)$
$$A_r (uD^r + L_1 D^{r-1} + \ldots).$$

Hence by § 24 we readily see that $uD^r A_r D^r u$ is of the required form. Accordingly we may write

$$u(A_0 + DA_1 D + \ldots + D^n A_n D^n)uv$$
$$= (B_0 + DB_1 D + \ldots + D^n B_n D^n)v \quad (36).$$

If $uv = \delta y$, we get from (35)

$$u\delta M = (B_0 + DB_1 D + \ldots + D^n B_n D^n)\frac{\delta y}{u} \ldots\ldots (37);$$

again, if $v = 1$ in (36), we have

$$u(A_0 + DA_1 D + \ldots + D^n A_n D^n)u = B_0 \ldots\ldots (38).$$

Hence, if u_1 be a solution of $(A_0 + DA_1 D + \ldots + D^n A_n D^n)u = 0$, that is, if it be a solution of $\delta M = 0$, the corresponding value of B_0 is 0. Consequently we have from (36)

$$u_1 \delta M = D(B_1 + DB_2 D + \ldots + D^{n-1} B_n D^{n-1}) D\frac{\delta y}{u_1}.$$

If $u_1 = \frac{1}{z_1}$, this becomes

$$\delta M = z_1 D (B_1 + DB_2 D + \ldots D^{n-1} B_n D^{n-1}) Dz_1 \delta y \ldots (39).$$

Again, the symbolic operator $B_1 + DB_2 D + \ldots + D^{n-1} B_{n-1} D^{n-1}$ can be transformed into $z_2 D(C_1 + DC_2 D + \ldots + D^{n-2} C_{n-1} D^{n-2}) Dz_2$, and so on. Finally we get

$$\delta M = z_1 Dz_2 D \ldots z_{n-1} Dz_n Dz_{n-1} \ldots Dz_2 Dz_1 \delta y \ldots\ldots (40).$$

Thus we obtain

$$\delta^2 U = \int_{x_0}^{x_1} \delta y z_1 Dz_2 D \ldots Dz_n D \ldots Dz_2 Dz_1 \delta y dx \ldots\ldots (41).$$

If we integrate by parts, then, since the limiting values of $y, \dot{y} \ldots$ are fixed, we get $\delta^2 U = -\int_{x_0}^{x_1} (Dz_1 \delta y)(z_2 Dz_3 \ldots z_2 Dz_1 \delta y) dx$, and after n successive integrations

$$\delta^n U = (-1)^n \int_{x_0}^{x_1} z_n (Dz_{n-1} Dz_{n-2} \ldots D_1 z\delta y)^2 dx \ (42).$$

Again, from (33) we see that $A_n = (-1)^n \frac{d^2 V}{dy^{(n)2}}$; also from (40) we find without difficulty

$$A_n = z_n (z_1 z_2 \ldots z_{n-1})^2 \ldots\ldots\ldots\ldots\ldots\ldots (43).$$

Hence we get finally

$$\delta^2 U = \int_{x_0}^{x_1} Q_n \left(\frac{Dz_{n-1} Dz_{n-2} \ldots Dz_1 \delta y}{z_{n-1} z_{n-2} \ldots z_1}\right)^2 dx \ldots\ldots\ldots (44),$$

where $Q_n = \frac{d^2 V}{dy^{(n)2}}$. From this it follows that the sign of $\delta^2 U$ depends in general on that of Q_n or $\frac{d^2 V}{dy^{(n)2}}$. Accordingly for a maximum or minimum solution it is necessary that Q_n should have the same sign for all values of x between the limits of integration, dx being supposed always positive. The reader will find no difficulty in applying this criterion to any of the examples which we have hitherto given.

26. A new and complete discussion of the criteria for the discrimination of maximum and minimum solutions has been given by Mr. Culverwell in *Trans. Roy. Soc.*, vol. clxxviii. (1887). Owing to want of space we can only make an allusion to this remarkable memoir, which contains an elementary investigation of the criteria for maxima and minima not only in the case of one but for any number of dependent variables, as also for multiple integrals.

27. We now proceed to the application of the calculus of variations to multiple integrals, commencing with the double integral $U = \int_{x_0}^{x_1}\int_{y_0}^{y_1} V dxdy$, where V is a function of x, y, z, p, q, r, s, and t, in which $p = \frac{dz}{dx}$, $q = \frac{dz}{dy}$, $r = \frac{d^2 z}{dx^2}$, $s = \frac{d^2 z}{dxdy}$, $t = \frac{d^2 z}{dy^2}$, in accordance with the ordinary notation.

Let $V_1 = \int_{y_0}^{y_1} V dy$, then $U = \int_{x_0}^{x_1} V_1 dx$; therefore by (6)

$$\text{we have } \delta U = \int_{x_0}^{x_1} \delta V_1 dx + \Big|_{x_0}^{x_1} V_1 dx$$

$$= \int_{x_0}^{x_1}\int_{y_0}^{y_1} \delta V dxdy + \int_{x_0}^{x_1}\Big|_{y_0}^{y_1} V\delta y dx + \Big|_{x_0}^{x_1} dx \int_{y_0}^{y_1} V_1 dy.$$

Again $\delta V = N\delta z + P\delta p + Q\delta q + R\delta r + S\delta s + T\delta t$, where $N = \frac{dV}{dz}$, $P = \frac{dV}{dp}$, $Q = \frac{dV}{dq}$, $R = \frac{dV}{dr}$, $S = \frac{dV}{ds}$, $T = \frac{dV}{dt}$. Hence

$$\int_{x_0}^{x_1}\int_{y_0}^{y_1} \delta V dxdy = \int_{x_0}^{x_1}\int_{y_0}^{y_1} (N\delta z + P\delta p + Q\delta q$$
$$+ R\delta r + S\delta s + T\delta t) dxdy \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (45).$$

In the transformation of this expression, we shall employ the following formulæ, which are easily established,

$$\int_{x_0}^{x_1}\int_{y_0}^{y_1} \frac{du}{dx} dxdy = \Big|_{x_0}^{x_1} dx \int_{y_0}^{y_1} udy - \int_{x_0}^{x_1}\Big|_{y_0}^{y_1} u\frac{dy}{dx} dx \ (46),$$

and $$\int_{x_0}^{x_1}\int_{y_0}^{y_1} \frac{du}{dy} dxdy = \int_{x_0}^{x_1}\Big|_{y_0}^{y_1} udx \ldots\ldots\ldots\ldots\ldots (47).$$

Hence we get $$\int_{x_0}^{x_1}\int_{y_0}^{y_1} P\frac{d\delta z}{dx} dxdy$$

$$= -\int_{x_0}^{x_1}\int_{y_0}^{y_1} \frac{dP}{dx}\delta z dxdy + \Big|_{x_0}^{x_1} dx \int_{y_0}^{y_1} P\delta z dy$$
$$- \int_{x_0}^{x_1}\Big|_{y_0}^{y_1} P\frac{dy}{dx}\delta z dy,$$

also $$\int_{x_0}^{x_1}\int_{y_0}^{y_1} Q\frac{d\delta z}{dy} dxdy$$

$$= -\int_{x_0}^{x_1}\int_{y_0}^{y_1} \frac{dQ}{dy}\delta z dxdy + \int_{x_0}^{x_1}\Big|_{y_0}^{y_1} Q\delta z dx.$$

Next, to transform $\int_{x_0}^{x_1}\int_{y_0}^{y_1} R\frac{d^2\delta z}{dx^2} dxdy$, we have

$$\int_{x_0}^{x_1}\int_{y_0}^{y_1} \left(R\frac{d^2\delta z}{dx^2} + \frac{dR}{dx}\frac{d\delta z}{dx}\right) dxdy$$

$$= \int_{x_0}^{x_1}\int_{y_0}^{y_1} \frac{d}{dx}\left(R\frac{d\delta z}{dx}\right) dxdy = \Big|_{x_0}^{x_1} dx \int_{y_0}^{y_1} R\frac{d\delta z}{dx} dy$$

$$-\int_{x_0}^{x_1}\Big|_{y_0}^{y_1} R\frac{d\delta z}{dx}\frac{dy}{dx}dx,$$

also
$$\int_{x_0}^{x_1}\int_{y_0}^{y_1}\left(\frac{dR}{dx}\frac{d\delta z}{dx}+\frac{d^2R}{dx^2}\delta z\right)dxdy$$
$$=\int_{x_0}^{x_1}\int_{y_0}^{y_1}\frac{d}{dx}\left(\frac{dR}{dx}\delta z\right)dxdy=\Big|_{x_0}^{x_1}dx\int_{y_0}^{y_1}\frac{dR}{dx}\delta zdy$$
$$-\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}\frac{dR}{dx}\frac{dy}{dx}\delta zdy.$$

Consequently, by subtraction,
$$\int_{x_0}^{x_1}\int_{y_0}^{y_1}\left(R\frac{d^2\delta z}{dx^2}-\frac{d^2R}{dx^2}\delta z\right)dxdy$$
$$=\Big|_{x_0}^{x_1}dx\int_{x_0}^{y_1}\left(R\frac{d\delta z}{dx}-\frac{dR}{dx}\delta z\right)dy$$
$$+\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}\left(\frac{dR}{dx}\delta z-R\frac{d\delta z}{dx}\right)\frac{dy}{dx}dx.$$

Again, in transforming the latter integral it is necessary to observe that y_1 and y_0 are functions of x, and accordingly that in that integral we have $\frac{d\delta z}{dx}=\frac{d}{dx}(\delta z)-\frac{dy}{dx}\frac{d\delta z}{dy}$; hence
$$-\int_{x_0}^{x_1}\Big|^{y_1}R\frac{d\delta z}{dx}\frac{dy}{dx}dx=\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}R\left(\frac{dy}{dx}\right)^2\frac{d\delta z}{dy}dx$$
$$-\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}R\frac{dy}{dx}\frac{d}{dx}(\delta z)dx,$$

also
$$\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}R\frac{dy}{dx}\frac{d}{dx}(\delta z)dy=\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}\frac{d}{dx}(R\frac{dy}{dx}\delta z)dy$$
$$-\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}\delta z\frac{d}{dx}\left(R\frac{dy}{dx}\right)dx.$$

But $\frac{d}{dx}\left(R\frac{dy}{dx}\right)=R\frac{d^2y}{dx^2}+\frac{dy}{dx}\left(\frac{dR}{dx}+\frac{dy}{dx}\frac{dR}{dy}\right)$; hence we get
$$\int_{x_0}^{x_1}\int_{y_0}^{y_1}R\frac{d^2\delta z}{dx^2}dxdy=\int_{x_0}^{x_1}\int_{y_0}^{y_1}\frac{d^2R}{dx^2}\delta zdxdy$$
$$+\Big|_{x_0}^{x1}\int_{y_0}^{y_1}\left(R\frac{d\delta z}{dx}-\frac{dR}{dx}\delta z\right)dy$$
$$+\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}\left\{R\frac{d^2y}{dx^2}+2\frac{dR}{dx}\frac{dy}{dx}+\frac{dR}{dy}\left(\frac{dy}{dx}\right)^2\right\}\delta zdx$$
$$+\int_{x_0}^{x_1}\Big|_{y^0}^{y_1}R\left(\frac{dy}{dx}\right)^2\frac{d\delta z}{dy}dx+\Big|_{x_0}^{x_1}\Big|_{y_0}^{y_1}R\frac{dy}{dx}\delta z\text{..................}(48).$$

Next, to transform $\int_{x_0}^{x_1}\int_{y_0}^{y_1}S\frac{d^2\delta z}{dxdy}dxdy$. Here
$$\int_{x_0}^{x_1}\int_{y_0}^{y_1}\left(S\frac{d^2\delta z}{dxdy}+\frac{dS}{dx}\frac{d\delta z}{dy}\right)dxdy$$
$$=\int_{x_0}^{x_1}\int_{y_0}^{y_1}\frac{d}{dx}\left(S\frac{d\delta z}{dy}\right)dxdy=\Big|_{x_0}^{x1}\int_{y_0}^{y_1}S\frac{d\delta z}{dy}dy$$
$$-\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}S\frac{d\delta z}{dy}\frac{dy}{dx}dx,$$

also
$$\int_{x_0}^{x_1}\int_{y_0}^{y_1}\left(\frac{dS}{dx}\frac{d\delta z}{dy}+\delta z\frac{d^2S}{dxdy}\right)dxdy=\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}\frac{dS}{dx}\delta zdx;$$

hence by subtraction
$$\int_{x_0}^{x_1}\int_{y_0}^{y_1}\left(S\frac{d^2\delta z}{dxdy}-\delta z\frac{d^2S}{dxdy}\right)dxdy$$
$$=\Big|_{x_0}^{x_1}\int_{y_0}^{y_1}S\frac{d\delta z}{dy}dy-\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}\left(\frac{dS}{dx}\delta z+S\frac{d\delta z}{dy}\frac{dy}{dx}\right)dx\text{..}(49).$$

Finally, to transform $\int_{x_0}^{x_1}\int_{y_0}^{y_1}T\frac{d^2\delta z}{dy^2}dxdy$, we have
$$\int_{x_0}^{x_1}\int_{y_0}^{y_1}\left(T\frac{d^2\delta z}{dy^2}+\frac{dT}{dy}\frac{d\delta z}{dy}\right)$$
$$=\int_{x_0}^{x_1}\int_{y_0}^{y_1}\frac{d}{dy}\left(T\frac{d\delta z}{dy}\right)dxdy=\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}T\frac{d\delta z}{dy}dx,$$

and
$$\int_{x_0}^{x_1}\int_{y_0}^{y_1}\left(\frac{dT}{dy}\frac{d\delta z}{dy}+\frac{d^2T}{dy^2}\delta z\right)dxdy=\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}\frac{dT}{dy}\delta zdx,$$

consequently
$$\int_{x_0}^{x_1}\int_{y_0}^{y_1}\left(T\frac{d^2\delta z}{dy^2}-\frac{d^2T}{dy^2}\delta z\right)dxdy$$
$$=\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}\left(T\frac{d\delta z}{dy}-\frac{dT}{dy}\delta z\right)dx\text{.....}(50).$$

Combining the preceding results, we get
$$\delta U=\delta\int_{x_0}^{x_1}\int_{y_0}^{y_1}Vdxdy$$
$$=\int_{x_0}^{x_1}\int_{y_0}^{y_1}\left(N-\frac{dP}{dx}-\frac{dQ}{dy}+\frac{d^2R}{dx^2}+\frac{d^2S}{dxdy}+\frac{d^2T}{dy^2}\right)\delta zdxdy$$
$$\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}\left(Q-P\frac{dy}{dx}+R\frac{d^2y}{dx^2}+2\frac{dR}{dx}\frac{dy}{dx}+\frac{dR}{dy}\left(\frac{dy}{dx}\right)^2\right.$$
$$\left.-\frac{dS}{dx}-\frac{dT}{dy}\right)\delta zdx+\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}\left(R\left(\frac{dy}{dx}\right)^2-S\frac{dy}{dx}+T\right)\frac{d\delta z}{dy}dx$$
$$+\int_{x_0}^{x_1}\Big|_{y_0}^{y_1}V\delta ydx+\Big|_{x_0}^{x_1}\int_{y_0}^{y_1}Vdxdy$$
$$+\Big|_{x_0}^{x_1}\int_{y_0}^{y_1}\left(P-\frac{dR}{dx}-\frac{dS}{dy}\right)\delta zdy+\Big|_{x_0}^{x_1}\int_{y_0}^{y_1}R\frac{d\delta z}{dx}dy$$
$$+\Big|_{x_0}^{x^1}\Big|_{y_0}^{y^1}\left(S-R\frac{dy}{dx}\right)\delta z\text{..................................}(51).$$

28. In many applications the limits of x and y are determined from a single equation. Thus, suppose the integral $U=\iint Vdxdy$ to express the sum of the elements $Vdxdy$ for all values of x and y which satisfy either $\phi(x, y)>0$ or $\phi(x, y)<0$, then the limits are given by the equation $\phi(x, y)=0$. In this case the preceding value of δU becomes much simplified, for y_0, $\mathfrak{z}_1$ are determined from the equation[1] $\phi=0$; and the extreme values of x are found by eliminating y between the equations $\phi=0$ and $d\phi/dy=0$. But these are the conditions that $\phi=0$ should have equal roots in y; we consequently infer that, when either $x=x_0$ or $x=x_1$, we have $y_0=y_1$. Hence we observe that $\Big|^{x_0}\int_{y_0}^{y_1}udy=0$ and $\Big|^{x_1}\int_{y_0}^{y_1}udy=0$ for all values of u, so that the last four terms in the expression for δU in (51) disappear in this case.

The methods and results of this and the preceding section can without difficulty be extended to triple and higher multiple integrals.

29. The method of application of the calculus of variations to the determination of maximum or minimum values of multiple definite integrals proceeds on the same principles as those already considered in § 9 for single integrals.

We shall limit the discussion to a brief consideration of the double integral $U=\iint Vdxdy$, in which V is a function of x, y, z, p, and q solely, and the limits are determined, as in § 28, by an equation of the form $\phi(x, y)=0$. Such problems readily admit of geometrical interpretation.

Here (51) reduces to
$$\delta U=\int_{x_0}^{x_1}\int_{y_0}^{y_1}\left(N-\frac{dP}{dx}-\frac{dQ}{dy}\right)\delta zdxdy$$
$$+{}_{x_0}^{x_1}\Big|_{y_0}^{y_1}\left\{\left(Q-P\frac{dy}{dx}\right)\delta z+V\delta y\right\}dx\text{............}(52).$$

Consequently, as in the case of single integrals, for a maximum or minimum value of U we must have
$$N-\frac{dP}{dx}-\frac{dQ}{dy}=0\text{.........................}53),$$

and
$$\Big|_{y_0}^{y_1}\left\{\left(Q-P\frac{dy}{dx}\right)\delta z+V\delta y\right\}=0\text{........}(54).$$

The former is in this case a partial differential equation of the second order, whose solution, whenever it can be obtained, consists of an equation between x, y, z having two arbitrary functions. The form of these functions in each case is to be determined by aid of (54) combined with the given limiting conditions of the problem. Thus, let us suppose the upper limit restricted to points in the surface $z=f_1(x, y)$, and let $p'=\frac{df_1}{dx}$, $q'=\frac{df_1}{dy}$; then $\delta\Big|^{y_1}z=\Big|^{y_1}q'\delta y$; and $\Big|^{y_1}(\delta z+q\delta y)=\Big|^{y_1}q'\delta y$. This gives

---

[1] If the equation $\phi=0$ gives for y several values, y_0, y_1, y_2, y_3, y_4 . . . then we substitute $\int Vdy=\int_{y_0}^{y_1}Vdy+\int_{y_2}^{y_3}Vdy+\ldots$, and each integral is to be treated as above.

$$\int^{y_1}\left\{\delta z+(q-q')\delta y\right\}=0\ \ldots\ldots\ldots\ldots\ldots(55).$$

Substituting in (54), we get

$$\int^{y_1}\left\{V+\left(Q-P\frac{dy}{dx}\right)(q'-q)\right\}=0\ldots(56).$$

Again, along the limiting curve we have $dz=pdx+qdy$ and $dz=p'dx+q'dy$; hence we get $\frac{dy}{dx}=-\frac{p'-p}{q'-q}$. Substituting in (56), we have along the limiting curve

$$V+P(p'-p)+Q(q'-q)=0\ \ldots\ldots\ldots\ldots(57).$$

A similar equation holds if the lower limit be restricted by another surface.

By aid of these equations the arbitrary functions involved in the solution of (53) are determinable. For example, to find the surface such that $\iint\mu dS$ shall be a minimum, dS being an element of the surface and μ a given function of the co-ordinates x, y, z. Here

$$V=\mu\sqrt{1+p^2+q^2},\ P=\frac{\mu p}{\sqrt{1+p^2+q^2}},\ Q=\frac{\mu q}{\sqrt{1+p^2+q^2}}.$$

Hence the equation

$$N-\frac{dP}{dx}-\frac{dQ}{dy}=0 \text{ leads to } \frac{d}{dx}\left(\frac{p}{\sqrt{1+p^2+q^2}}\right)$$

$$+\frac{d}{dy}\left(\frac{q}{\sqrt{1+p^2+q^2}}\right)=\frac{1}{\mu\sqrt{1+p^2+q^2}}\left\{\frac{d\mu}{dz}-p\frac{d\mu}{dx}-q\frac{d\mu}{dy}\right\},$$

$$\text{or } \frac{1}{R}+\frac{1}{R'}=-\frac{1}{\mu}\left(\cos\alpha\frac{d\mu}{dx}+\cos\beta\frac{d\mu}{dy}+\cos\gamma\frac{d\mu}{dz}\right)\ldots\ldots\ldots(58),$$

where R and R' are the principal radii of curvature of the surface at the point, and α, β, γ the angles which the normal to the surface makes with the co-ordinate axes. Again, if we suppose the surface limited by two fixed surfaces, the equation $V+P(p'-p)+Q(q'-q)=0$ reduces to

$$1+pp'+qq'=0\ \ldots\ldots\ldots\ldots\ \ldots\ldots\ldots\ldots(59).$$

This shows that the surface intersects each of its bounding surfaces orthogonally. As a particular case of (58) we infer that the surface of minimum area is in general such that its principal radii of curvature at every point are equal and of opposite signs. A remarkable investigation of the equation of this surface was given by Bonnet in *Liouville's Journal*, 1860. Again, in the surface of given area and of maximum volume we have $V=z-a\sqrt{1+p^2+q^2}$. The equation $N-\frac{dP}{dx}-\frac{dQ}{dy}=0$ readily leads in this case to $\frac{1}{R}+\frac{1}{R'}=a$.

30. The principles and method of the calculus of variations are largely employed in all branches of mathematics, both pure and applied. Want of space prevents our entering into any account of such application. The reader will find the history of this calculus fully detailed in Todhunter's treatise, already mentioned. The most important recent work in English is Mr. Carll's *Calculus of Variations*, New York and London, 1885. (B. W.)

VARICOSE VEINS. See SURGERY, vol. xxii. p. 719.

VARLEY, CORNELIUS (1781–1873), water-color painter, a younger brother of John Varley (see below), was born at Hackney, London, on 21st November, 1781. He was educated by his uncle, a philosophical instrument maker, and under him acquired a knowledge of the natural sciences; but about 1800 he joined his brother in a tour through Wales, and began the study of art. He was soon engaged in teaching drawing. From 1803 till 1859 he was an occasional exhibitor in the Royal Academy; and he also contributed regularly to the displays of the Water-Color Society, of which, in 1803, he was one of the founders, and of which he continued a member till 1821. His works, which are not numerous, consist mainly of carefully finished classical subjects, with architecture and figures. He published a series of etchings of Boats and other Craft on the River Thames, and during his life as an artist he continued deeply interested in scientific pursuits. For his improvements in the camera lucida, the camera obscura, and the microscope he received the Isis gold medal of the Society of Arts; and at the International Exhibition of 1851 he gained a medal for his invention of the graphic telescope. He died at Hampstead on 2d October, 1873.

VARLEY, JOHN (1778–1842), water-color painter, was born at Hackney, London, on 17th August, 1778. His father, a man of scientific attainments and tutor in the family of Lord Stanhope, discouraged his leanings towards art, and placed him under a silversmith. But on his parent's death Varley escaped from this uncongenial employment, and, after working with a portrait painter, engaged himself at the age of sixteen to an architectural draughtsman, who took him on a provincial tour to sketch the principal buildings in the towns they visited. His spare hours were employed in sketching from nature, and in the evenings he was permitted, like Turner and Girtin, to study in the house of Dr. Munro. In 1798 he exhibited his first work, a View of Peterborough Cathedral, in the Royal Academy. In 1799 he visited North Wales, and in its wild mountain scenery found the subjects best suited to his brush. He returned to the same district in 1800, and again in 1802, and the impressions then received powerfully influenced the whole course of his art. In 1804 he became a foundation member of the Water-Color Society, and contributed over forty works to its first exhibition. He had married in the previous year; and, in order to provide for the wants of an increasing family, he was obliged to produce for the dealers much work of a slight and commonplace character. He also taught drawing, and some of his pupils, such as John Linnell and William Hunt, afterwards became celebrated. He was a firm believer in astrology, skilful in casting horoscopes; and some curious instances were related of the truth of his predictions. It was at his house that his friend William Blake sketched his celebrated Visionary Heads. Varley died at London on 17th November, 1842.

Varley's landscapes are graceful and solemn in feeling, and simple and broad in treatment, being worked with a full brush and pure, fresh, transparent tints, usually without any admixture of body-color. Though his works are rather mannered and conventional, they are well considered and excellent in composition. Some of his earlier water-colors, including his Views of the Thames, were painted upon the spot, and possess greater individuality than his later productions, which are mainly compositions of mountain and lake scenery, produced without direct reference to nature. Among his literary works are *Zodiacal Physiology*, 1828; *Observations on Color and Sketching from Nature*, 1830; *A Practical Treatise on Perspective, and Principles of Landscape Design of Young Artists.*

VARNA, a fortified town and seaport of Bulgaria, in 43° 12′ N. lat, and 27° 56′ E. long., about midway between the Danube delta and the Bosphorus, lies on the north side of the Bay of Varna, at the opening of the Pravadi valley, 5 miles wide and skirted by hills on both sides. The town, which covers the slope of one of these hills, facing seawards, comprises Greek, Bulgarian, Turkish, Jewish, and Gypsy quarters, with a total population (1888) of 25,256 (8449 Bulgarians, 7569 Turks, 5423 Greeks). It has many finely built houses and shops. Its principal buildings are the gymnasium, a hospital, the barracks, and several churches and mosques. Amongst the industrial establishments are soap factories, breweries, distilleries, and tanneries. More than 3,740,000 gallons of wine are made annually within the department of Varna. The town is well supplied with good water and is not unhealthy. Although open to the south and southeast, the bay affords safe anchorage, being sheltered from the north and northeast winds. Through the Pravadi it communicates with Lake Devno, which, if connected, as has been proposed, by a navigable canal with the bay, would form one of the best harbors in the Euxine. Varna is the chief outlet for the grain and agricultural produce of Bulgaria for Constantinople and the west of Europe, the export of grain in 1887 amounting in value to £244,210 [$1,186,860.60] (total exports, £349,030 [$1,696,285.80]) and the total imports to £580,300 [$2,820,258]. It lies 48 miles east of Shumla (Shumna), with which it is connected by the main Bulgarian railway, running thence to the Danube at Rustchuk,—these three fortresses forming with Silistria (on the Danube) the Bulgarian "quadrilateral." The old stone walls of Varna have been destroyed to make room for earth-fortifications.

Varna has been identified with the ancient Milesian colony of *Odessus* on the coast of Mœsia Inferior. It figures largely in the history of more recent times, and close by was fought in 1444 the battle in which Amurath (Murad) II. slew the Hungarian King Ladislaus, and routed his forces commanded by the renowned John Hunyady. Varna was occupied in 1828 by the Russians, in 1854 by the allies, who here organized the invasion of the Crimea, and in 1877 by the Egyptian troops summoned to the defence of Turkey against the Russians. The following year it was ceded to the principality of Bulgaria. It has long been the seat of a Greek metropolitan and since 1870 of a Bulgarian bishop.

VARNHAGEN VON ENSE, KARL AUGUST, (1785–1858), German biographer, was born at Düsseldorf on 21st February, 1785. He went to Berlin to study medicine, but devoted his attention chiefly to philosophy and literature, which he afterwards studied more thoroughly at Hamburg, Halle and Tübingen. He began his literary career in 1804 as joint editor with A. von Chamisso of a *Musenalmanach.* In 1809 he joined the Austrian army, and was wounded at the battle of Wagram. Soon afterwards he accompanied his superior officer, Prince Bentheim, to Paris, where he carried on his studies. In 1812 he joined the Prussian civil service at Berlin, but in the following year resumed his military career, this time as a captain in the Russian army. He accompanied Tettenborn to Hamburg and Paris, and his experiences were recorded in his *Geschichte der Hamburger Ereignisse* (1813) and his *Geschichte der Kriegszüge Tettenborn's* (1814). At Paris he entered the diplomatic service of Prussia, and in 1814 acted under Hardenberg at the Congress of Vienna. He also accompanied Hardenberg to Paris in 1815. He was resident minister for some time at Carlsruhe, but was recalled in 1819, after which he lived chiefly at Berlin as a privy councillor of legation (*Geheimer Legationsrath*). He had no fixed official appointment, but was often employed in important political business.

In 1814 he married Rahel Antonie Friederike, originally called Levin, afterwards Robert. She was born in 1771 at Berlin, where she died in 1833. By birth she was a Jewess; but before her marriage she made profession of Christianity. Although she never wrote anything for publication, she was a woman of remarkable intellectual qualities and exercised a powerful influence on many men of high ability. Her husband, who was devotedly attached to her, found in her sympathy and encouragement one of the chief sources of his inspiration as a writer. After her death he published a selection from her papers, and afterwards much of her correspondence was printed. Varnhagen von Ense never fully recovered from the shock caused by her death. He himself died suddenly in Berlin on 10th October, 1858.

He made some reputation as an imaginative and critical writer, but he is famous chiefly as a biographer. He possessed a remarkable power of grouping facts so as to bring out their essential significance, and his style is distinguished for its strength, grace and purity. Among his principal works are *Goethe in den Zeugnissen der Mitlebenden* (1824); *Biographische Denkmale* (five vols., 1824–30); and "Lives" of General von Seydlitz (1834), Sophia Charlotte, queen of Prussia (1837), Field-Marshal Schwerin (1841), Field-Marshal Keith (1844), and General Bülow von Dennewitz (1853). His *Denkwürdigkeiten und vermischte Schriften* appeared in seven volumes in 1837–46. After his death were published two additional volumes of *Denkwürdigkeiten,* some volumes of his correspondence with eminent men, his *Tagebücher* (14 vols.) *Blätter aus der preussischen Geschichte* (5 vols.), and *Biographische Porträts.* His selected writings appeared in nineteen volumes in 1871–76.

VARNISH. A varnish is a fluid preparation which, when spread out in thin layers, dries either by evaporation or by chemical action into a hard, transparent, and glossy film. Varnishes are used to communicate lustre and brilliance to many different kinds of dressed surfaces,—metal-work, wood, paint, paper, leather, etc.,—and to protect such surfaces from the influence of air and damp. The chief requisites of a good varnish are that it forms a firmly-adherent layer on the surface over which it is spread, that it dries hard, yet with sufficient elasticity and tenacity not to crack with changes of temperature, that it forms a glossy durable surface, and that it dries quickly. The materials which almost exclusively form the permanent body of varnishes are the drying oils and resinous substances, the chief of which are the copals, lac, dammar, elemi, amber, sandarac, mastic, and rosin. For certain forms of varnish the drying oils themselves act as the solvent for the resins, but in other cases volatile solvents are employed. The solvents chiefly used are methylated spirit, wood spirit, ether, benzine, and turpentine and other essential oils. Soluble coloring ingredients are also, in some cases, used in varnishes and lacquers, those principally available being gamboge, dragon's blood, aloes, cochineal, turmeric, and coal-tar dyes.

According to the solvents employed, the ordinary kinds of varnish are divided into three classes—(1) spirit, (2) turpentine, and (3) oil varnishes. Spirit varnishes dry with great rapidity owing to the volatilization of the solvent spirit, leaving a coating of pure resin of great hardness and brilliance, but the film is deficient in tenacity, cracking and scaling readily on exposure. The resin lac, either as grain, shell or bleached lac, is the basis of most spirit varnishes; but sandarac is also largely used, and to these are added in varying proportions the softer resins,—elemi, Venice turpentine, Canada balsam, mastic, etc.,—which give elasticity and tenacity to the varnish. The solvent is almost exclusively methylated spirit. The resins are ground and mixed with powdered glass, which prevents the resinous particles from agglutinating, and thus facilitates the solvent action of the spirit. The solution is effected by agitation in closed vessels with the aid of heat, and the varnish when strained off must be kept tightly closed from the air. Spirit varnishes are used principally for cabinet-work and turnery, stationery, gilding and metal-work. Colored spirit varnishes and lacquers are largely employed for metal-work, for imitation gilding and bronzing, for toys, etc. Turpentine is the solvent principally used for making dammar varnish, the solution being effected by powdering the resin and boiling it with a proportion of spirit of turpentine, after which more turpentine is added in the cold state to bring the preparation to a proper consistency. To increase the tenacity of such dammar varnish some proportion of boiled linseed oil or of oil copal varnish may be added. In place of oil of turpentine other essential oils may be used as solvents, and in practice oil of spike is largely utilized in preparing fine varnishes for oil paintings. Turpentine varnishes are also made in which the principal resinous bodies are sandarac and common rosin; and, moreover, turpentine is largely employed to reduce the consistency and to improve the drying properties of copal varnishes. The basis or solvent of oil or fatty varnishes consists principally of linseed oil; but the other drying oils—poppy and walnut, etc.—may also be used. These oils, without the addition of resins, themselves form varnishes which on exposure in thin layers dry by a process of oxidation into tough glossy films; but the drying proceeds very slowly unless the oils are previously boiled with the red oxide of lead or otherwise treated to increase their power of absorbing oxygen (see LINSEED OIL, vol. xiv. p. 683). It is in the form of boiled oil or of oil prepared with driers that these oils are used in varnish-making. Oil varnishes thus differ from the other classes in the circumstance that the principal solvent is not volatile and dissipated on exposure, but in itself forms an essential and permanent ingredient in the preparation.

The resin principally used in oil varnishes is copal, and its varieties differ very much in hardness, that is, in the temperature at which they melt and distil. Hard and semi-hard copals can only be made to mix with and dissolve in oils at the temperature at which they distil, which ranges from 230° to 360° C. The copal in varnish-making is melted and brought to the requisite temperature in a copper vessel. Simultaneously the oil is heated to the boiling-point in a separate copper vessel, and at the proper moment a measured quantity of the boiling oil is added to the liquefied resin. They are then boiled together till the mixture becomes perfectly clear, and by a series of alternate additions of oil and resin at proper temperatures the solution is brought to the desired consistency. After the mixture of oil and resin has sufficiently cooled, oil of turpentine in certain proportion is added. The making of copal varnish is attended with great risk of burning, and special precautions have to be observed for the extinction of the fire that frequently bursts out in these highly-heated and most inflammable bodies. Copal varnish is also made by boiling together the requisite proportions of resin and oil under pressure in a closed vessel, and subsequently adding turpentine, or by dissolving the resin and turpentine at the high heat and adding the oil afterwards. Amber varnish is prepared by the same methods as those followed in preparing copal, but, the resin being still more refractory and insoluble, a higher heat is required. A peculiar varnish forms the basis of the celebrated Japanese lacquer. The substance is a resinous exudation, which is obtained by making incisions in the bark of the Japanese urushi or lacquer-tree, *Rhus vernicifera*. The resinous juice on settling in vats separates into two layers, the upper and thinner of which, on mixture with a drying oil, forms a transparent varnish, having a rich yellow color, which dries into coatings of remarkable tenacity, durability, and lustre (see JAPANNING, vol. xiii. p. 603).

VARRO, MARCUS TERENTIUS, Roman polymath and man of letters, lived from 116 to 27 B.C. When he was born, the Gracchan agitation had only just been laid to rest, and the year of his death saw the final and formal establishment of the empire. Into the changing life of that stirring time Varro entered deeply, and there was no current in thought, culture, literature, and even politics, with which he was not closely in contact. Few have ever so thoroughly combined the pursuit of scholarship and literature with experience of practical affairs. Dionysius of Halicarnassus well described him as the man of widest experience during his age. Nothing is known of Varro's ancestors but that they were natives of the Sabine country, where Varro himself was born in the town of Reate. Here he imbibed in his earlier years a good measure of the hardy simplicity and strong seriousness which the later Romans attributed to the men of the early republic,—characteristics which were supposed to linger in the Sabine land after they had fled from the rest of Italy. The chief teacher of Varro was L. Ælius Stilo, the first systematic student, critic, and teacher of Latin philology and literature, and of the antiquities of Rome and Italy. We know from Cicero that Varro also studied at Athens, especially under the philosopher Antiochus of Ascalon. It was the aim of this teacher to lead back the Academic school from the skepticism of Arcesilaus and Carneades to the tenets of the early Platonists, as he understood them. His opponents, however, declared that he identified Platonism with Stoic dogmatism, and that a very slight change in his views would have converted him into a Stoic of the Stoics. When Cicero wrote his *Posterior Academics*, he introduced Varro as an interlocutor, and made him expound the views of Antiochus. The influence of Antiochus is most plainly to be traced in the extant remains of Varro's writings, and indirectly in works like the *De Civitate Dei* of Augustine, which owe much to Varro. In spite of controversial statements to the contrary, the differences between Antiocheanism and Stoicism were great and marked, and it is a serious, though a common, error to treat Varro as an adherent of the Stoic school. The political career of Varro seems to have been late and slow; but he arrived at the prætorship, after having been tribune of the people, quæstor, and curule ædile. In politics and war he followed Pompey's lead; but it is probable that he was discontented with the course on which his leader entered when the first triumvirate was formed, and he may thus have lost his chance of rising to the consulate. He actually ridiculed the coalition in a work entitled the *Three-Headed Monster* (Τρικάρανον in the Greek of Appian). He did not, however, refuse to join the commission of twenty by whom the great agrarian scheme of Cæsar for the resettlement of Capua and Campania was carried into execution (59 B.C.). Despite the difference between them in politics, Varro and Cæsar had literary tastes in common, and were friends in private life. Under Pompey Varro saw much active service; he was attached to Pompey as pro-quæstor, probably during the war against Sertorious in Spain. We next find him, as legate, in command of a fleet which kept the seas between Delos and Sicily, while Pompey was suppressing the pirates, and he even won the "naval crown," a coveted reward of personal prowess. A little later he was legate during the last Mithradatic war. In the conflict between Cæsar and the Pompeian party Varro was more than once actively engaged. In his *Civil War* (ii. 17–20) Cæsar tells how Varro, when legate in Spain along with Afranius and Petreius, lost his two legions without striking a blow, because the whole region where he was quartered joined the enemy. Cæsar curiously intimates that, though Varro did his best for Pompey from a sense of duty, his heart was really with the other leader. Nevertheless he proceeded to Epirus before the battle of Pharsalia, and awaited the result at Dyrrachium in the company of Cicero and Cato. Like Cicero, Varro received harsh treatment from Mark Antony after the Pompeian defeat. Some of his property was actually plundered, but restored at the bidding of Cæsar, to whom Varro in gratitude immediately dedicated one of his most important writings. The dictator employed the scholar in aiding him to collect and arrange great stores of Greek and Latin literature for the vast public library which he intended to found. We have glimpses of Varro at this time in the *Letters* of Cicero. The two, though alike in political inclinations and in their love for literature, were antipathetic in their natures,—the one soft in fibre, and vain, richly abundant in expression, and subtly sensitive, the other somewhat harsh, severe, and retiring, solid in learning, and no master of literary form. The impression of Varro's personality which Cicero gives is unattractive enough, but probably on the whole true. The formation of the second triumvirate again plunged Varro into danger. Antony took possession anew of the property he had been compelled to surrender, and inserted Varro's name on the list of the proscribed. His friends, however, afforded him protection. He was able to make peace with the triumvirs, but sacrificed his property and much of his beloved library. He was permitted to spend in quiet study and in writing the last fifteen years of his life. He is said to have died (27 B.C.) almost pen in hand.

Varro was not surpassed in the compass of his writings by any ancient, not even by any one of the later Greek philosophers, to some of whom tradition ascribes a fabulous number of separate works. In a passage quoted by Gellius, Varro himself, when over seventy years of age, estimated the number of "books" he had written at 490; but "book" here means, not merely such a work as was not subdivided into portions, but also a portion of a subdivided work. For example, the *Menippean Satires* numbered 150, and are all counted separately in Varro's estimate. Jerome made or copied a catalogue of Varro's works which has come down to us in a mutilated form. From this and from other extant materials Ritschl has set down the number of the distinct literary works at 74 and the number of separate "books" at about 620. The later years of the author's life were therefore even more fruitful than the earlier. The complete catalogue may be roughly arranged under three heads,—(1) belles lettres, (2) history and antiquities, (3) technical treatises on philosophy, law, grammar, mathematics, philology and other subjects.

The first of these three classes no doubt mainly belonged to Varro's earlier life. In poetry he seems to have attempted nothing that was very elaborate, and little of a serious character. His genius tended naturally in the direction of burlesque and satire. In belles lettres he showed himself throughout, both in matter and form, the pupil and admirer of Lucilius. He wrote satires in the style of his master, and he may be one of those to whom Horace alludes (*Sat.*, i. 10, 47) as having "tried satire in vain." One poetical work probably consisted of short pieces in the style of the more satirical poems of Catullus. It is doubtful whether, as has often been supposed, Varro wrote a philosophical poem somewhat in the style of Lucretius; if so, it should rather be classed with the prose technical treatises. One curious production was an essay in popular illustrated literature, which was almost unique in ancient times. Its title was *Imagines*, and it consisted of 700 prose biographies of Greek and Roman celebrities, with a metrical *elogium* for each, accompanied in each case by a portrait. But the lighter works of Varro have perished almost to the last line, with the exception of numerous fragments of the *Menippean Satires.* The Menippus whom Varro imitated lived in the first half of the third century B.C., and was born a Phœnician slave. He became a Cynic philosopher, and is a figure familiar to readers of Lucian. He flouted life and all philosophies but the Cynic in light compositions, partly in prose and partly in verse. The fragments of Varro's imitations have been frequently collected and edited, most recently by Riese and by Bücheler. The glowing and picturesque account of these fragments given by Mommsen in his *History of Rome* is known to all students of Roman literature, but few readers could pass from Mommsen's picture to a careful study of the passages themselves without severe disappointment. That the remains exhibit variety and fertility, that there are in them numerous happy strokes of humor and satire, and many felicitous phrases and descriptions, is true, but the art is on the whole heavy, awkward, and forced, and the style rudely archaic and untasteful. The Latin is frequently as rough and uncouth as that of Lucilius. No doubt Varro contemned the Hellenizing innovations by which the hard and rude Latin of his youth was transformed into the polished literary language of the late republican and the Augustan age. The titles of the *Menippean Satires* are very diverse. Sometimes personal names are chosen, and they range from the gods and demigods to the slaves, from Hercules to Marcipor. Frequently a popular proverb or catchword in Greek or Latin supplies the designation: thus we have as titles "I've got You;" (Ἔχω σε); "You don't Know what Evening is to Bring" (*Nescis quid vesper serus vehat*); "Know Thyself" (Γνῶθι σεαυτόν). Occasionally the heading indicates that the writer is flying at some social folly, as in "Old Men are Children for the Second Time;" (Δὶς παῖδες οἱ γέροντες) and in the "Bachelor" (*Cælebs*). In many satires the philosophers were pounded, as in the "Burial of Menippus" and "Concerning the Sects" (Περὶ αἱρεσέων). Each composition seems to have been a genuine medley or "lanx satura": any topic might be introduced which struck the author's fancy at the moment. There are many allusions to persons and events of the day, but political bitterness seems to have been commonly avoided. The whole tone of the writer is that of a "laudator temporis acti," who can but scoff at all that has come into fashion in his own day. From the numerous citations in later authors it is clear that the *Menippean Satires* were the most popular of Varro's writings. Not very unlike the *Menippean Satires* were the *Libri Logistorici*, or satirical and practical expositions, possibly in dialogue form, of some theme most commonly taken from philosophy on its ethical side. A few fragments in this style have come down to us and a number of titles. These are twofold: that is to say, a personal name is followed by words indicating the subject-matter, as *Marius, de Fortuna*, from which the contents may easily be guessed, and *Sisenna, de Historia*, most likely a dialogue in which the old annalist of the name was the chief speaker, and discoursed of the principles on which history should be written. Among the lighter and more popular works may be mentioned twenty-two books of *Orations* (probably never spoken), some funeral eulogies (*Laudationes*), some "exhortations" (*Suasiones*), conceivably of a political character, and an account of the author's own life.

The second section of Varro's works, those on history and antiquities, form to the present day the basis on which a large part of our knowledge of the earlier Roman history, and in particular of Roman constitutional history, ultimately rests. These writings were used as a quarry by the compilers and dilettanti of later times, such as Pliny, Plutarch, Gellius, Festus, Macrobius, and by Christian champions like Tertullian, Arnobius, and Augustine, who did not disdain to seek in heathen literature the means of defending their faith. These men have saved for us a few remains from the great wreck made by time. Judging from what has been casually preserved, if any considerable portion of Varro's labors as antiquarian and historian were to be now discovered, scholars might find themselves compelled to reconstruct the earlier history of the Roman republic from its very foundations. Varro's greatest predecessor in this field of inquiry, the man who turned over the virgin soil, was Cato the Censor. His example, however, seems to have remained unfruitful till the time of Varro's master, Lucius Ælius Stilo Præconinus. From his age to the decay of Roman civilization there were never altogether wanting men devoted to the study of their nation's past; but none ever pursued the task with the advantages of Varro's comprehensive learning, his indefatigable industry, and his reverent, yet discriminating regard for the men and the institutions of the earlier ages. The greatest work of this class was that on *Antiquities*, divided into forty-one books. Of these the first twenty-five were entitled the *Antiquities of Human Things* (*Antiquitates Rerum Humanarum*), while the remaining sixteen were designated the *Antiquities of Things Divine* (*Antiquitates Rerum Divinarum*). The book was the fruit of Varro's later years, in which he gathered together the material laboriously amassed through the period of an ordinary lifetime. The second division of the work was dedicated to Cæsar as supreme pontiff. The design was as far-reaching as that of the *Natural History* of Pliny. The general heads of the exposition in the secular portion of the book were four,—(1) "who the men are who act (*qui agant*), (2) the places in which they act (*ubi*), (3) the times at which they act (*quando*), (4) the results of their action (*quid agant*)." In the portion relating to divine affairs there were divisions parallel to these four, with a fifth, which dealt with the gods in whose honor action in divine affairs is taken. Our knowledge of this great book is to a large extent derived from the works of the early Christian writers, and especially from Augustine's *De Civitate Dei.* These lights of the church, as was natural, directed their attention mainly to the portion which treated of the religion of Rome. A glance at the authorities quoted in such a book as Preller's *Römische Mythologie* will suffice to show how largely the imperfect indeed, but nevertheless invaluable information now attainable concerning the older and un-Hellenized forms of Roman and Italian religious rites depends on the citations by Christian authorities from the *Antiquitates Rerum Divinarum.* It is a great misfortune that no similar series of citations from the secular part of the *Antiquitates* has come down to us. Most of the other historical and antiquarian writings of Varro were special elaborations of topics which he could not treat with sufficient fulness and minuteness in the larger book. The treatise on the *Genealogy of the Roman People* dealt mainly with the relation of Roman chronology to the chronology of Greece and the East. Dates were assigned even to mythological occurrences, because Varro believed in the theory of Euhemerus, that all the beings worshipped as gods had once lived as men. To Varro's researches are due the traditional dates assigned to the era of the kings and to that of the early republic. Minor writings of the same class were the *De Vita Populi Romani*, apparently a kind of history of Roman civilization; the *De Familiis Trojanis*, an account of the families who "came over" with Æneas; the *Ætia* (Αἴτια), an explanation of the origin of Roman customs, on which Plutarch drew largely in his *Quæstiones Romanæ*; a *Tribuum Liber*, used by Festus; and the constitutional handbook written for the instruction of Pompey when he became consul. Nor must the labor expended by Varro in the study of literary history be forgotten. His activity in this direction, as in others, took a wide range. One of his greatest achievements was to fix the canon of the genuine plays of Plautus. The "Varronian plays" were the twenty which have come down to us, along with one which has been lost.

The third class of treatises, which we have called technical, was also numerous and very varied. Philosophy, grammar, the history and theory of language, rhetoric, law, arithmetic, astronomy, geometry, mensuration, agriculture, naval tactics, were all represented. The only works of this kind which have come down to our days are the *De Lingua Latina* (in part) and the *De Re Rustica.* The former originally comprised twenty-five books, three of which (the three succeeding the first) are dedicated to a P. Septimius who had served with the author in Spain and the last twenty-one to Cicero. The whole work was divided into three main sections, the first dealing with the origin of Latin words, the second with their inflections and other modifications, the third with syntax. The books still preserved (somewhat imperfectly) are those from the fifth to the tenth inclusive. The Latin style is harsh, rugged, and far from lucid. As Mommsen remarks, the clauses of the sentences are often arranged on the thread of the relative pronoun like thrushes on a string. The arrangement of the subject-matter, while pretending to much precision, is often far from logical. The fifth, sixth, and seventh books give Varro's views on the etymology of Latin words. The principles he applies are those which he had learned from the philosophers of the Stoic school,—Chrysippus, Antipater, and others. The study of language as it existed in Varro's day was thoroughly dominated by Stoic influences. Varro's etymologies could be only *a priori* guesses, but he was well aware of their character, and very clearly states at the outset of the fifth book the hindrances that barred the way to sound knowledge. He was thoroughly alive to the importance of not arguing merely from the forms and meanings of words as they existed in his day, and was fully conscious that language and its mechanism should be studied historically. The books from the eighth to the tenth inclusive are devoted to the inflections of words and their other modifications. These Varro classes all under the head of "declinatio," which implies a swerving aside from a type. Thus *Herculi* from *Hercules* and *manubria* from *manus* are equally regarded as examples of *declinatio*. Varro adopts a compromise between the two opposing schools of grammarians, those who held that nature intended the *declinationes* of all words of the same class to proceed uniformly (which uniformity was called *analogia*) and those who deemed that nature aimed at irregularity (*anomalia*). The matter is treated with considerable confusion of thought. But the *facts* incidentally cited concerning old Latin, and the statements of what had been written and thought about language by Varro's predecessors, are of extreme value to the student of Latin. The other extant prose work, the *De Re Rustica*, is in three books, each of which is in the form of a dialogue, the circumstances and in the main the interlocutors being different for each. The dramatic introductions and a few of the interludes are bright and interesting, and the Latin style, though still awkward and unpolished, is far superior to that of the *De Lingua Latina*.

A complete collection of the remains of Varro is still a desideratum. The fragments of the different treatises have been partially collected in many separate publications of recent date. The best editions of the *De Lingua Latina* are those by C. O. Müller and L. Spengel (re-edited by his son in 1885). The most recent and best recension of the *De Re Rustica* is that of Keil (Leipsic, 1884). Of modern scholars Ritschl has deserved best of Varro. Several papers in his *Opuscula* treat of the nature of Varro's works which have not come down to us. (J. S. R.)

VARRO, Publius Terentius, with the cognomen Atacinus, a Roman poet whose life extended from 82 to about 37 B.C. The name Atacinus, given to distinguish him from the more famous Varro of Reate, is drawn from Atax, the name of a small district or river in Norbonensian Gaul, near to which he was born. He was perhaps the first Roman born beyond the Alps who reached to eminence in literature. He seems to have taken at first Ennius and Lucilius as his models, and wrote an epic, entitled *Bellum Sequanicum*, eulogizing the exploits of Cæsar in Gaul and Britain, and also *Satires*, of which Horace speaks slightingly. Jerome has preserved a statement that Varro began to study Greek literature with great avidity in his thirty-fifth year. The last ten years of his life were given up to the imitation of Greek poets of the Alexandrian school. Quintilian (indirectly confirming the judgment of Horace concerning the *Satires*) says that Varro made his name as an *interpres operis alieni*—"a translator of other men's works," for such is the force of the word *interpres*. Even in this capacity Quintilian bestows on him restricted praise as "by no means to be despised." But Quintilian probably much undervalued the Roman imitators of the Alexandrians, Catullus included. From other evidence we may conclude that, though he had not sufficient power to excel in the historical epic or in the serious work of the Roman *satira*, Varro yet possessed in considerable measure the lighter gifts which we admire in Catullus. His chief poem of the later period was the *Argonautica*, modelled, somewhat closely it would seem, on the epic of Apollonius Rhodius. The age was prolific of epics, both historical and mythological, and that of Varro seems to have held a high rank among them. Ovid asks what age will ever be unacquainted with the story of the first ship as told by Varro. In one of Ovid's lists of Roman poets Varro stands between Ennius and Lucretius, while in another he is linked with Virgil. Statius, in his poem on the birthday of Lucan, gives to the epic of Varro an equally distinguished place. Later he published erotic poems, probably in the elegiac metre. These Propertius seems to have valued highly, for in a well-known passage he ranks the Leucadia celebrated by Varro along with the Lesbia of Catullus, the Quintilia of Calvus, the Lycoris of Gallus, and his own Cynthia. The other titles which have been preserved are the *Cosmographia*, or *Chorographia*, a poem on geography, imitated from the Greek of Alexander, an Ephesian, described by Cicero (*Att.*, ii. 22) as a careless man and no good poet; and the *Ephemeris*, a poem on weather-signs, in hexameters, after Aratus. The Varro whom Quintilian (i. 4, 4) mentions in company with Lucretius as author of a poem on philosophy can hardly have been either Varro of Atax or Varro of Reate. The fragments of Varro Atacinus which remain, about fifty lines in all, are put together by Riese at the end of his edition of the fragments of the greater Varro's *Menippean Satires;* but there is not enough of them to enable us to form a judgment on his style.

VASA, Gustavus. See Gustavus I.

VÁSÁRHELY. See Hódmezö-Vasarhely and Maros-Vásárhely.

VASARI, Giorgio (1513–1574), a painter and architect whose main distinction rests on his valuable history of Italian art,[1] was born at Arezzo in 1513. At a very early age he became a pupil of Guglielmo da Marsiglia, a very skilful painter of stained glass. At the age of sixteen he went to Florence, where he studied under Michelangelo and Andrea del Sarto, aided by the patronage of the Medici princes. In 1529 he visited Rome and studied the works of Raphael and others of his school. The paintings of Vasari were much admired by the rapidly degenerating tastes of the 16th century; but they possess the smallest amount of merit, being in the main feeble parodies of the powerful works of Michelangelo. Vasari was largely employed in Florence, Rome, Naples, Arezzo, and other places. Many of his pictures still exist, the most important being the wall and ceiling paintings in the great hall of the Palazzo Vecchio in Florence, and his frescos on the cupola of the cathedral, which, however, were not completed at the time of his death. As an architect he was perhaps more successful; the loggia of the Uffizi by the Arno, and the long passage connecting it with the Pitti Palace, are his chief works. Unhappily he did much to injure the fine mediæval churches of S. Maria Novella and Santa Croce, from both of which he removed the original rood-screen and loft, and remodelled the retro-choir in the degraded taste of his time. Vasari enjoyed a very high repute during his lifetime and amassed a considerable fortune. He built himself in 1547 a fine house in Arezzo, and spent much labor in decorating its walls and vaults with paintings. He was elected one of the municipal council or priori of his native town, and finally rose to the supreme office of gonfaloniere. He died at Florence on 27th June, 1574.

Personally Vasari was a man of upright character, free from vanity, and always ready to appreciate the works of others: in spite of the narrow and meretricious taste of his time, he expresses a warm admiration of the works of such men as Cimabue and Giotto, which is very remarkable. As an art historian of his country he must always occupy the highest rank. His great work was first published in 1550, and afterwards partly rewritten and enlarged in 1568, bearing the title *Delle Vite de' piu Eccellenti Pittori, Scultori, ed Architettori.* It was dedicated to Cosimo de' Medici, and was printed at Florence by the Giunti; it is a small quarto illustrated with many good woodcut portraits. This *editio princeps* of the complete work is usually bound in three volumes, and also contains a very valuable treatise on the technical methods employed in all branches of the arts, entitled *Le Tre Arti del Disegno, cioè Architettura, Pittura, e Scoltura.*

---

[1] Vasari gives a sketch of his own biography at the end of his *Vite*, and adds further details about himself and his family in his lives of Lazzaro Vasari and Francesco Salviati. He was related to the painter Luca Signorelli.

The best edition of Vasari's works is that published at Florence by Milanesi, 1878–82, which embodies the valuable notes in the earlier edition by Le Monnier. The *Lives* has been translated into French, German, and English (by Mrs. Foster, London, 1850). They are written in a very pleasant style, interspersed with amusing stories, and are in the main trustworthy, except some of the biographies of early artists.[2] With a few exceptions Vasari's judgment is acute and unbiassed.

VASCO DA GAMA. See GAMA, VASCO DA.

VASCULAR SYSTEM.

THE term *vascular system* designates all the arrangements in the body connected with the circulation of the blood. A description of the anatomy of the various organs as found in man is given under ANATOMY (vol. i. p. 789 *sq.*), and an account of various modifications of the circulatory apparatus under the headings designating the great groups of the animal kingdom, such as MOLLUSCA, CRUSTACEA, ICHTHYOLOGY, AMPHIBIA, REPTILES, BIRDS; and reference may be made to the articles NUTRITION and RESPIRATION for details as to the formation, physical and chemical properties, and functions of the blood. The present article is devoted to a consideration of the mechanism by which the circulation is carried on in the *Mammalia* and in man, a branch of physiology which has been more successfully investigated than any other department of the science.

HISTORICAL SKETCH.

Galen.

Galen, following Erasistratus and Aristotle, clearly distinguished arteries from veins, and was the first to overthrow the old theory of Erasistratus that the arteries contained air. According to him, the vein arose from the liver in two great trunks, the *vena porta* and *vena cava.* The first was formed by the union of all the abdominal veins, which absorbed the chyle prepared in the stomach and intestines, and carried it to the liver, where it was converted into blood. The vena cava arose in the liver, divided into two branches, one ascending through the diaphragm to the heart, furnishing the proper veins of this organ; there it received the *vena azygos*, and entered the right ventricle, along with a large trunk from the lungs, evidently the pulmonary artery. The vena azygos was the *superior vena cava*, the great vein which carries the venous blood from the head and upper extremities into the right auricle. The descending branch of the great trunk supposed to originate in the liver was the *inferior vena cava*, below the junction of the hepatic vein. The arteries arose from the left side of the heart by two trunks, one having thin walls, the pulmonary veins, the other having thick walls, the aorta. The first was supposed to carry blood to the lungs, and the second to carry blood to the body. The heart consisted of two ventricles, communicating by pores in the septum; the lungs were parenchymatous organs communicating with the heart by the pulmonary veins. The blood-making organ, the liver, separates from the blood subtle vapors, the *natural spirits*, which, carried to the heart, mix with the air introduced by respiration, and thus form the *vital spirits;* these, in turn carried to the brain, are elaborated into *animal spirits*, which are distributed to all parts of the body by the nerves.[1] Such were the views of Galen, taught until early in the 16th century.

Vesalius.

Jacobus Berengarius of Carpi (*ob.* 1527) investigated the structure of the valves of the heart. Andreas Vesale or Vesalius (1514–1564) contributed largely to anatomical knowledge, especially to the anatomy of the circulatory organs. He determined the position of the heart in the chest; he studied its structure, pointing out the fibrous rings at the bases of the ventricles; he showed that its wall consists of layers of fibres connected with the fibrous rings; and he described these layers as being of three kinds,—straight or vertical, oblique, and circular or transverse. From the disposition of the fibres he reasoned as to the mechanism of the contraction and relaxation of the heart. He supposed that the relaxation, or diastole, was accounted for principally by the longitudinal fibres contracting so as to draw the apex towards the base, and thus cause the sides to bulge out; whilst the contraction, or systole, was due to contraction of the transverse or oblique fibres. He showed that the pores of Galen, in the septum between the ventricles, did not exist, so that there could be no communication between the right and left sides of the heart, except by the pulmonary circulation. He also investigated minutely the internal structure of the heart, describing the valves, the *columnæ carneæ*, and the *musculi papillares.* He described the mechanism of the valves with much accuracy. He had, however, no conception either of a systemic or of a pulmonary circulation. To him the heart was a reservoir from which the blood ebbed and flowed, and there were two kinds of blood, arterial and venous, having different circulations and serving different purposes in the body. Vesalius was not only a great anatomist: he was a great teacher; and his pupils carried on the work in the spirit of their master. Prominent among them was Gabriel Fallopius (1523–1562), who studied the anastomoses of the bloodvessels, without the art of injection, which was invented by Frederick Ruysch (1638–1731) more than a century later. Another pupil was Columbus (Matthieu Reald Columbo, *ob.* 1559), first a prosector in the anatomical rooms of Vesalius and afterwards his successor in the chair of anatomy in Padua; his name has been mentioned as that of one who anticipated Harvey in the discovery of the circulation of the blood. A study of his writings clearly shows that he had no true knowledge of the circulation, but only a glimpse of how the blood passed from the right to the left side of the heart. In his work there is evidently a sketch of the pulmonary circulation, although it is clear that he did not understand the mechanism of the valves, as Vesalius did. As regards the systemic circulation, there is the notion simply of an oscillation of the blood from the heart to the body and from the body to the heart. Further, he upholds the view of Galen, that all the veins originate in the liver; and

Columbus.

---

[1] See Burggraeve's *Histoire de l'Anatomie*, Paris, 1880, in which he refers to many of the older authors, also to the articles GALEN and ANATOMY.

[2] As in most other kindred subjects the tendency of modern criticism is to underestimate the historical accuracy of Vasari's work.

he even denies the muscular structure of the heart.[1]

Servetus.

In 1553 Michael Servetus (1511–1553), a pupil or junior fellow-student of Vesalius, in his *Christianismi Restitutio*, described accurately the pulmonary circulation.[2] Servetus perceived the course of the circulation from the right to the left side of the heart through the lungs, and he also recognized that the change from venous into arterial blood took place in the lungs and not in the left ventricle. Not so much the recognition of the pulmonary circulation, as that had been made previously by Columbus, but the discovery of the respiratory changes in the lungs constitutes Servetus's claim to be a pioneer in physiological science.

Cesalpino.

Andrea Cesalpino (1519–1603), a great naturalist of this period, also made important contributions towards the discovery of the circulation, and in Italy he is regarded as the real discoverer.[3] Cesalpinus knew the pulmonary circulation. Further he was the first to use the term "circulation," and he went far to demonstrate the systemic circulation. He experimentally proved that, when a vein is tied, it fills below and not above the ligature. The following passage from his *Quæstiones Medicæ* (lib. v., cap. 4, fol. 125), quoted by Gamgee, shows his views:

> "The lungs, therefore, drawing the warm blood from the right ventricle of the heart through a vein like an artery, and returning it by anastomosis to the venal artery (pulmonary vein), which tends towards the left ventricle of the heart, and air, being in the meantime transmitted through the channels of the aspera arteria (trachea and bronchial tubes), which are extended near the venal artery, yet not communicating with the aperture as Galen thought, tempers with a touch only. This circulation of the blood (*huic sanguinis circulationi*) from the right ventricle of the heart through the lungs into the left ventricle of the same exactly agrees with what appears from dissection. For there are two receptacles ending in the right ventricle and two in the left. But of the two only one intromits; the other lets out, the membranes (valves) being constituted accordingly."

Discovery of circulation of blood.

Still Cesalpinus clung to the old idea of there being an efflux and reflux of blood to and from the heart, and he had confused notions as to the veins conveying nutritive matter, whilst the arteries carried the vital spirits to the tissues. He does not even appear to have thought of the heart as a contractive and propulsive organ, and attributed the dilatation to "an effervescence of the spirit," whilst the contraction,—or, as he termed it, the "collapse,"—was due to the appropriation by the heart of nutritive matter. Whilst he imagined a communication between the termination of the arteries and the commencement of the veins, he does not appear to have thought of a direct flow of blood from the one to the other. Thus he cannot be regarded as the true discoverer of the circulation of the blood. More recently Ercolani has put forward claims on behalf of Carlo Ruini as being the true discoverer. Ruini published the first edition of his anatomical writings in 1598, the year William Harvey entered at Padua as a medical student. This claim has been carefully investigated by Gamgee, who has come to the conclusion that it cannot be maintained.[4]

Harvey.

The anatomy of the heart was examined, described, and figured by Bartolomeo Eustacheo (*c.* 1500–1574) and by Julius Cæsar Aranzi or Arantius (*c.* 1530–1589), whose name is associated with the fibro-cartilaginous thickenings on the free edge of the semilunar valves (*corpora Arantii*). Hieronymus Fabricius of Acquapendente (1537–1619), the immediate predecessor and teacher of Harvey, made the important step of describing the valves in the veins; but he thought they had a subsidiary office in connection with the collateral circulation, supposing that they diverted the blood into branches near the valves; thus he missed seeing the importance of the anatomical and experimental facts gathered by himself. At the time when Harvey arose the general notions as to the circulation may be briefly summed up as follows: the blood ebbed and flowed to and from the heart in the arteries and veins; from the right side at least a portion of it passed to the left side through the vessels in the lungs, where it was mixed with air; and, lastly, there were two kinds of blood,—the venous, formed originally in the liver, and thence passing to the heart, from which it went out to the periphery by the veins and returned by those to the heart, and the arterial,—containing "spirits" produced by the mixing of the blood and the air in the lungs—sent out from the heart to the body and returning to the heart by the same vessels. The pulmonary circulation was understood so far, but its relation to the systemic circulation was unknown. The action of the heart, also, as a propulsive organ was not recognized. It was not until 1628 that Harvey announced his views to the world by publishing his treatise *De Motu Cordis et Sanguinis* (see vol. xi. pp. 449, 450). His conclusions are given in the following celebrated passage:

> "And now I may be allowed to give in brief my view of the circulation of the blood, and to propose it for general adoption. Since all things, both argument and ocular demonstration, show that the blood passes through the lungs and heart by the auricles and ventricles, and is sent for distribution to all parts of the body, where it makes its way into the veins and pores of the flesh, and then flows by the veins from the circumference on every side to the centre, from lesser to the greater veins, and is by them finally discharged into the vena cava and right auricle of the heart, and this in such a quantity, or in such a flux and reflux, thither by the arteries, hither by the veins, as cannot possibly be supplied by the ingestor, and is much greater than can be required for mere purposes of nutrition, it is absolutely necessary to conclude that the blood in the animal body is impelled in a *circle*, and is in a state of ceaseless motion, that this is the act or function which the heart performs by means of its pulse, and that it is the sole and only end of the motion and contraction of the heart" (bk. x. ch. xiv. p. 68).

Capillary circulation.

Opposed by Caspar Hofmann of Nuremberg, Veslingius of Padua, and J. Riolanus the younger, this new theory was supported by Roger Drake, a young Englishman, who chose it for the subject of a graduation thesis at Leyden in 1637, by Rolfink of Jena, and especially by Descartes, and quickly gained the ascendant; and its author had the satisfaction of seeing it confirmed by the discovery of the capillary circulation, and universally adopted. The circulation in the capillaries between the arteries and the veins was discovered by Marcellus Malpighi (1628–1694) of Bologna in 1661. He saw it first in the lungs and the mesentery of a frog, and the discovery was announced in the second of two letters, *Epistola de Pulmonibus*, addressed to Borelli, and dated 1661.[5] Malpighi actually showed the capillary circulation to the astonished eyes of Harvey. Anthony van Leeuwenhoek (1632–1723) in 1673 repeated Malpighi's observations, and studied the capillary circulation in a bat's wing, the tail of a tadpole, and the tail of a fish. William Molyneux studied the circulation in the lungs of a water newt in 1683.[6]

The idea that the same blood was propelled through

Transfer of blood.

the body in a circuit suggested that life might be sustained by renewing the blood in the event of some of it being lost. About 1660 Lower, a London physician (died 1691), succeeded in transferring the blood of one animal directly from its bloodvessels into those of another animal. This was first done by passing a "quill" or a "small crooked pipe of silver or brass" from the carotid artery of one dog to the jugular vein of another.[1] This experiment was repeated and modified by Sir Edmund King, Coxe, Gayant, and Denys with such success as to warrant the operation being performed on man, and accordingly it was carried out by Lower and King on 23d November, 1667, when blood from the arteries of a sheep was directly introduced into the veins of a man.[2] It would appear that the operation had previously been performed with success in Paris.

Force of heart and velocity of blood.

Borelli.

Keill.

Hales.

Thomas Young.

The doctrine of the circulation being accepted, physiologists next directed their attention to the force of the heart, the pressure of the blood in the vessels, its velocity, and the phenomena of the pulse wave. Giovanni Alphonso Borelli (1608–1679) investigated the circulation during the lifetime of Harvey. He early conceived the design of applying mathematical principles to the explanation of animal functions; and, although he fell into many errors, he must be regarded as the founder of animal mechanics. In his *De Motu Animalium* (1680–85) he stated his theory of the circulation in eighty propositions, and in prop. lxxiii., founding on a supposed relation between the bulk and the strength of muscular fibre as found in the ventricles, erroneously concluded that the force of the heart was equal to the pressure of a weight of 180,000 ℔. He also recognized and figured the spiral arrangement of fibres in the ventricles. The question was further investigated by James Keill, a Scottish physician (1673–1719), who in his *Account of Animal Secretion, the Quantity of Blood in the Human Body, and Muscular Motion* (1708) attempted to estimate the velocity of blood in the aorta, and gave it at 52 feet per minute. Then, allowing for the resistance of the vessels, he showed that the velocity diminishes towards the smaller vessels, and arrived at the amazing conclusion that in the smallest vessels it travels at the rate of ¼ inch in 278 days,—a good example of the extravagant errors made by the mathematical physiologists of the period. Keill further described the hydraulic phenomena of the circulation in papers communicated to the Royal Society and collected in his *Essays on Several Parts of the Animal Economy* (1717). In these essays, by estimating the quantity of blood thrown out of the heart by each contraction, and the diameter of the aortic orifice, he calculated the velocity of the blood. He stated (pp. 84, 87) that the blood sent into the aorta with each contraction would form a cylinder 8 inches (2 ounces) in length and be driven along with a velocity of 156 feet per minute. Estimating then the resistances to be overcome in the vessels, he found the force of the heart to be "little above 16 ounces,"—a remarkable difference from the computation of Borelli. Keill's method was ingenious, and is of historical interest as being the first attempt to obtain quantitative results; but it failed to obtain true results, because the data on which he based his calculations were inaccurate. These calculations attracted the attention not only of the anatomico-physiologists, such as Haller, but also of some of the physicists of the time, notably of Jurin and D. Bernoulli. Jurin (died 1750) gave the force of the left ventricle at 9 ℔ 1 oz. and that of the right ventricle at 6 ℔ 3 oz. He also stated with remarkable clearness, considering that he reasoned on the subject as a physicist, without depending on experimental data gathered by himself, the influence on the pulse induced by variations in the power of the heart or in the resistance to be overcome.[3] The experimental investigation of the problem was supplied by Stephen Hales (1677–1761), rector of Teddington in Middlesex, who, in 1708, devised the method of estimating the force of the heart by inserting a tube into a large artery and observing the height to which the blood was impelled into it. Hales is the true founder of the modern experimental method in physiology. He observed in a horse that the blood rose in the vertical tube, which he had connected with the crural artery, to the height of 8 feet 3 inches perpendicular above the level of the left ventricle of the heart. But it did not attain its full height at once: it rushed up about half way in an instant, and afterwards gradually at each pulse 12, 8, 6, 4, 2, and sometimes 1 inch. When it was at its full height, it would rise and fall at and after each pulse 2, 3, or 4 inches; and sometimes it would fall 12 or 14 inches, and have there for a time the same vibrations up and down at and after each pulse as it had when it was at its full height, to which it would rise again after forty or fifty pulses.[4] He then estimated the capacity of the left ventricle by a method of employing waxen casts, and, after many such experiments and measurements in the horse, ox, sheep, fallow deer, and dog, he calculated that the force of the left ventricle in man is about equal to that of a column of blood 7½ feet high, weighing 51½ ℔, or, in other words, that the pressure the left ventricle has to overcome is equal to the pressure of that weight. When we contrast the enormous estimate of Borelli (180,000 ℔) with the underestimate of Keill (16 oz.), and when we know that the estimate of Hales, as corroborated by recent investigations by means of elaborate scientific appliances, is very near the truth, we recognize the far higher service rendered to science by careful and judicious experiment than by speculations, however ingenious. With the exception of some calculations by Dan Bernoulli in 1748, there was no great contribution to hæmadynamics till 1808, when two remarkable papers appeared from Thomas Young (1773–1829). In the first, entitled "Hydraulic Investigations," which appeared in the *Phil. Trans.*, he investigated the friction and discharge of fluids running in pipes and the velocity of rivers, the resistance occasioned by flexures in pipes and rivers, the propagation of an impulse through an elastic tube, and some of the phenomena of pulsations. This paper was preparatory to the second, "On the Functions of the Heart and Arteries,"—the Croonian lecture for 1808—in which he showed more clearly than had hitherto been done (1) that the blood-pressure gradually diminishes from the heart to the periphery; (2) that the velocity of the blood becomes less as it passes from the greater to the smaller vessels; (3) that the resistance is chiefly in the smaller vessels, and that the elasticity of the coats of the great arteries comes into play in overcoming this resistance in the interval between systoles; and (4) that the contractile coats do not act as propulsive agents, but assist in regulating the distribution of blood.[5]

Use of instruments.

The next epoch of physiological investigation is characterized by the introduction of instruments for accurate measurement, and the graphic method of registering phenomena, now so largely used in science.[6] In 1825 appeared E. and W. Weber's *Wellenlehre*, and in 1838 E. Weber's *Ad Notat. Anatom. et Physiolog.*, i., both of which contain an exposition of E. H. Weber's *schema* of the circulation, a scheme which presents a true and consistent theory. In 1826 Poiseuille invented the hæmadynamometer.[1] This was adapted with a marker to a recording cylinder by Ludwig, in 1847, so as to form the instrument named by Volkmann the kymograph. Volkmann devised the hæmadromometer for measuring the velocity of the blood in 1850; for the same purpose Vierordt constructed the hæmatachometer in 1858; Chauveau and Lortet first used their hæmadromograph in 1860; and lastly, Ludwig and Dogiel obtained the best results as regards velocity by the "stream-clock" in 1867. As regards the pulse, the first sphygmograph was constructed by Vierordt in 1856; and Marey's form, of which there are now many modifications, appeared in 1860. In 1861 Chauveau and Marey obtained tracings of the variations of pressure in the heart cavities (see p. 108 below) by an experiment which is of great historical importance. During the past twenty-five years vast accumulations of facts have been made through the instruments of precision above alluded to, so that the conditions of the circulation, as a problem in hydrodynamics, have been thoroughly investigated. Since 1845, when the brothers Weber discovered the inhibitory action of the vagus, and 1858, when Claude Bernard formulated his researches showing the existence of a vaso-motor system of nerves, much knowledge has been acquired as to the relations of the nervous to the circulatory system. The Webers, John Reid, Claude Bernard, and Carl Ludwig may be regarded as masters in physiology equal in standing to those whose researches have been more especially alluded to in this historical sketch. The Webers took the first step towards recognizing the great principle of inhibitory action; John Reid showed how to investigate the functions of nerves by his classical research on the eighth pair of cranial nerves; Claude Bernard developed the fundamental conception of vaso-motor nerves; and Ludwig showed how this conception, whilst it certainly made the hydraulic problems of the circulation infinitely more complicated than they were even to the scientific imagination of Thomas Young, accounted for some of the phenomena and indicated at all events the solidarity of the arrangements in the living being. Further, Ludwig and his pupils used the evidence supplied by some of the phenomena of the circulation to explain even more obscure phenomena of the nervous system, and they taught pharmacologists how to study in a scientific manner the physiological action of drugs.

PHYSIOLOGY, ETC., OF CIRCULATION.

Vessels and course of circulation.

The blood is contained during life in a continuous system of more or less elastic and contractile vessels. These are (1) the *arteries*, terminating in (2) the *capillaries*, from which originate (3) the *veins*, whilst a special contractile organ, (4) the *heart*, is placed at the commencement of the arteries and the termination of the veins (see Fig. 1). The heart may be regarded as a double organ, each half consisting of an auricle and a ventricle, the right half containing blood which has been returned from the body to be sent to the lungs, and the left half containing blood which has been returned from the lungs to be distributed to the body. There are thus, in a sense, two circulations,—the one pulmonary, from the right side of the heart, by the pulmonary artery to the lungs, through the capillaries of the lungs, and back to the left side of the heart by the pulmonary veins, and the other systemic, from the left side of the heart, by the aorta, and the arteries which ramify from it, to the capillaries throughout the tissues, and from thence by the veins to the right side of the heart. Thus the course of the circulation may be traced (1) from right auricle to right ventricle, through the right auriculo-ventricular opening, guarded by the tricuspid valve; (2) from right ventricle by the pulmonary artery, through the capillaries of the lungs, to the pulmonary veins, which open into the left auricle; (3) from left auricle to left ventricle, through the left auriculo-ventricular opening, guarded by the mitral valve; (4) from the left ventricle through the greater arteries, the medium sized arteries, and the arterioles into the capillaries of the tissues and organs; and (5) from thence by the veins, opening into larger and larger trunks, so as ultimately to constitute the superior and inferior venæ cavæ, which open into the right auricle, the point from which we started. Remembering that the walls of these tubes are all more or less elastic, imagine them to be distended with blood; there would then be a condition of permanent tension, which would be varied if pressure were applied to any part of the system. Such a variation of pressure would produce a movement of the fluid in the direction of less pressure, and, as the fluid cannot escape, there would be a circulation, which would be carried in the same direction by mechanical arrangements of valves. In the living body the contractions of the heart force blood into the arterial system and increase the pressure in that part of the circulation; the arteries empty part of their contents into the capillaries, which carry the blood to the veins, so as to tend to an equalization of pressure between the venous and arterial systems. If the pressure in both systems became equal, there would be no circulation; but, as the veins pour a portion of the blood back again into the heart, this organ on being refilled again contracts, forcing more blood into the arterial system and again raising the pressure there; thus the possibility during life of an equalization of arterial and venous pressure is prevented. In describing more fully the mechanism by which this circulation is maintained we shall consider (1) the action of the heart, and (2) the action of the bloodvessels, arteries, capillaries, and veins.

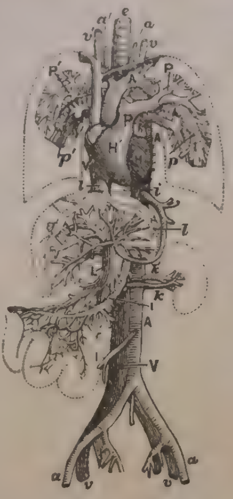

FIG. 1.—General course of circulation and some of principal vessels. H′, right ventricle; H, left ventricle; A, A, aorta; *k*, part of left auricle; P, pulmonary artery, going to lungs; P′, pulmonary veins; *v*, ascending or lower vena cava; *e*, trachea or wind-pipe; *p*, *p′*, bronchial tubes; *a′*, *a*, right and left carotid arteries; *v*, *v′*, veins from root of neck (internal jugular and subclavian), joining to form descending or upper vena cava; *i*, hepatic artery; *l*, hepatic vein; I, superior mesenteric artery, going to mesentery and bowels; L, portal vein, going to liver; *k′*, renal artery; *k*, renal vein; V, inferior vena cava, splitting into the two iliac veins, *v*, *v*. The Action of the Heart.

Physiological anatomy.

The form, position, and general arrangements of the heart are described under ANATOMY (vol. i. pp. 790, 791), and it is only necessary here to allude to certain points of physiological importance.

Muscular structure.

The substance of the heart is composed of a special variety of muscular tissue, along with connective tissue, bloodvessels, lymphatics, nerves, and ganglia. The muscular fibres are of an irregularly cubical form, faintly striated transversely, from $\frac{1}{500}$ to $\frac{1}{350}$ inch in length by $\frac{1}{1600}$ to $\frac{1}{1000}$ inch in breadth, destitute of sarcolemma, frequently having bands at the broad ends by which they anastomose, and showing an oval nucleus. A large mass of fibrous tissue and fibro-cartilage (which in some animals, as the ox, is bony) is found at the base of the heart, in the angle between the aortic and two

[1] Magendie's *Journal*, vol. viii. p. 272.

auriculo-ventricular openings; from it processes pass in various directions, and form the bases of the fibrous or tendinous rings of the auriculo-ventricular and arterial openings, and to these many if not all of the bands of muscular fibre are attached. These bands are arranged in layers. According to Pettigrew (1864), there are seven layers of fibres forming the wall of each ventricle,—three external, one central, and three internal,—and they are so arranged that the first or outer external layer is continuous with the seventh or inner internal layer, the second with the sixth, and the third with the fifth. Ludwig (1849) gives a simpler arrangement,—(1) an outer longitudinal layer extending from the base, where the fibres are attached to the tendinous structures around the orifices, and passing obliquely towards the apex to enter by a twist into the interior of the ventricle; (2) an inner longitudinal layer composed of the same fibres of the outer layer,—some of these becoming continuous with the papillary muscles (Fig. 2) and others forming an irregular stratum of fibres, which terminate in the fibrous rings at the base of the ventricle (Fig. 3); and (3) an intermediate or transverse layer, the thickest of the three, formed of fibres passing with less and less obliquity until they are transverse. These arrangements are shown in Figs. 4 and 5, and they account for the following physiological phenomena. (1) The auricles contract independently of the ventricles. So long as the rhythmic movement is normal, the auricular contractions are equal in number to the ventricular; but, as the heart dies, there may be several beats of the auricle for one of the ventricle, and at last only the auricles contract. The auricular portion of the right auricle is the last to cease beating; hence it is termed the *ultimum moriens*. Sometimes also contractions of the vena cava and pulmonary veins may be noticed after the heart beats have ceased. (2) The contraction of the circular fibres around the orifices of the veins empties these vessels into the auricles; and no doubt these fibres have also a sphincter-like action during the contraction of the cavities, preventing the regurgitation of blood, and thus doing away with the necessity for valves at these orifices. (3) The double arrangement of fibres around the auricles produces, when the fibres contract, a uniform diminution of the auricular cavity. (4) The spiral arrangement of the fibres in the ventricular walls expels the blood with great force, as if it were propelled by wringing or twisting the walls of the cavity.

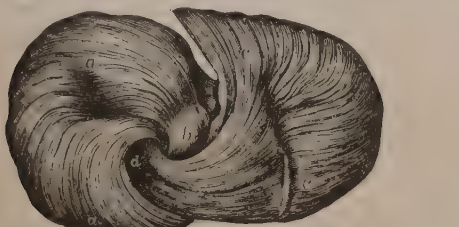

FIG. 4.—View of fibres of sheep's heart dissected at apex to show the "vortex." *a*, *a*, fibres entering apex posteriorly at *b*; *c*, *c*, fibres entering apex anteriorly at *d*. (Pettigrew, Quain's *Anatomy*.)

Valves of heart.

The valves of the heart are as follows (see ANATOMY, vol. i. p. 791, Fig. 89). (1) The tricuspid guards the right auriculo-ventricular opening, and consists of three flaps, formed of fibrous tissue (containing many elastic fibres) covered with endocardium. These flaps are continuous at their base, forming an annular membrane surrounding the auricular opening, and they are kept in position by the *chordæ tendineæ*, which are attached to their ventricular surfaces and free margins. (2) The bicuspid or mitral valve, at the left auriculo-ventricular orifice, consists of two pointed segments or cusps, having the same structure as those of the tricuspid valve. The auriculo-ventricular valves contain striated muscular fibres, radiating from the auricles into the segments of the valve. These probably shorten the valves towards their base and make a larger opening for the passage of the blood into the ventricles. A concentric layer of fibres, found near the base of the segments, has a sphincter-like action, approximating the base of the valves (Paladino). Some of the larger chordæ tendineæ contain striated muscle (Oehl), whilst a delicate muscular network exists in the valvulæ Thebesii (guarding the openings of small veins from the substance of the heart into the right auricle) and in the Eustachian valve (a crescentic fold of membrane in front of the opening of the inferior vena cava) (Landois). The aortic and pulmonary openings are guarded by the sigmoid or semilunar valves, each of which consists of three semicircular flaps, each flap being attached by its convex border to the wall of the artery, whilst its free border projects into the interior of the vessel. The segments consist of fibrous tissue covered with endocardium. At the middle of the free border there is a fibro-cartilaginous thickening called the nodulus or corpus Arantii. From this nodulus numerous tendinous fibres radiate to the attached border of the valve, but along the margin of the valve the membrane is thin and destitute of such fibres. These thin parts are called the *lunulæ*. Opposite each semilunar flap there is a bulging of the wall of the vessel, the *sinuses of Valsalva*. In the aorta these are situated one anteriorly and two posteriorly (right and left). From the anterior arises the right coronary artery, and from the left posterior the left coronary artery,—these vessels being for the supply of blood to the substance of the heart (Quain).

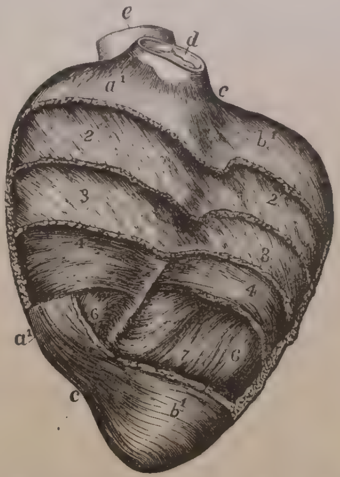

FIG. 5.—View of partial dissection of fibres in anterior wall of ventricles in a sheep's heart, showing different degrees of obliquity of fibres. At the base and apex the superficial fibres are displayed in the intervening space; more and more of the fibres have been removed from above downwards, reaching to a greater depth on the left than on the right side. a^1, a^1, superficial fibres of right ventricle; b^1, b^1, superficial fibres of left ventricle; 2, superficial fibres removed so as to expose those underneath, which have the same direction as the superficial ones over the left ventricle, but a different direction from those over the right ventricle; at 3 some of these have been removed, but the direction is only slightly different; 4, transverse or annular fibres occupying middle of thickness of ventricular walls; 6, 7, internal fibres passing downwards towards apex to emerge at the whorl; *c*, *c*, anterior coronary or interventricular groove, over which the superficial fibres cross; in the remaining part of the groove some of the deep fibres turn backwards into the septum; *d*, pulmonary artery; *e*, aorta. (Allen Thomson, Quain's *Anatomy*.)

Dimensions and weight.

According to Laennec, the size of the heart is about equal to the closed fist of the individual. Its mean weight is about 9 to 10 oz. John Reid's tables give the average weight in the adult male as 11 oz. and in the female as 9 oz. The proportion of the weight of the heart to that of the body is from 1 to 150 to 1 to 170 (Quain). W. Müller gives the ratio of heart weight to body weight in the child, and until the body weighs 88 ℔, as .176 oz. to 2.2 ℔; when the body weight is from 110 to 200 ℔ the ratio is .141 oz. to 2.2 ℔; and when the weight of the body reaches 220 ℔ the ratio is as .123 oz. to 2.2 ℔. The volume of the heart, according to Beneke, is as follows: new-born infant, 1.34 cubic inches; 15 years of age, 9.15 to 9.76; at 20 years, 15.25; up to the 50th year, 17.08 cubic inches; after that there is a slight diminution. There is scarcely any difference between the capacities of the two ventricles, although in the ordinary modes of death the right is always found more capacious than the left, probably because it is distended with blood; the left ventricle after death is usually empty and more contracted. The wall of the left ventricle is much thicker than that of the right. The specific gravity of heart muscle is 1.069. The thickness of the left ventricle in the middle is in man .44 inch and in woman .43; that of the right is .16 and .14 inch respectively. The circumference of the tricuspid orifice in man is 4.62 inches and in woman 4.33; of the mitral, 4.13 and 3.78 respectively. The circumference of the pulmonary artery is 2.94 inches; of the aorta, 2.77; of the superior vena cava, .702 to 1.05 inch; of the inferior vena cava, 1.05 to 1.4; and the diameter of the pulmonary veins, .53 to .62.

Modes of examining living heart.

When the hand is applied to the side, a little to the left of the left nipple, and in the interval between the fifth and sixth ribs, a shock or impulse is felt. If the whole hand be placed flat over the region of the heart, one may notice the presence or absence of the heart-beat, also its situation and extent, and any alterations in its character. In some rare cases, where there is a congenital fissure of the sternum, the finger can be applied to various parts of the heart's surface, with the integuments and pericardium intervening. This mode of examination may be termed *palpation*. Again, when the ear is applied, either directly, or indirectly by means of the stethoscope, over the position of the heart, sounds are heard the duration and rhythm of which are of physiological significance. This mode is known as *auscultation*. By *percussing* over the region of the heart the anatomical limits of the organ may be exactly defined, and information obtained as to its actual size, as to any alterations in the relation of the lungs to the heart, and as to the presence or absence of fluid in the pericardium. The direct registration of the movements of the heart has been accomplished by the aid of various recording instruments.[1]

Movements of heart.

The movements of the heart consist of a series of contractions which succeed each other with a certain rhythm. The period of contraction is called the *systole*, and that of relaxation the *diastole*. The two auricles contract and relax synchronously, and these movements are followed by a simultaneous contraction and relaxation of the ventricles. Thus there is a systole and diastole of the auricles and a systole and diastole of the ventricles. But in each half of the heart the contractions and relaxations of the auricle and the contractions and relaxations of the ventricle are successive. Finally, there is a very short period in which the heart is entirely in diastole. The whole series of movements, from the commencement of one auricular systole to the commencement of the one immediately following, is known as the *cardiac cycle* or *period of revolution* of the heart. In Fig. 6 the systole is represented by the curve above the horizontal lines and the diastole by the curve below them. The auricular changes are traced on the upper line *au* and those of the ventricle on the lower line *vent*. The length of the lines represents the total duration of a cardiac revolution. The diagram shows that the auricular systole occupies one-fifth of the total time of a revolution of the heart and the ventricular systole two-fifths, that the auricular systole immediately precedes the ventricular systole, that the commencement of the ventricular systole coincides with the commencement of the auricular diastole, and that during two-fifths of the total period both auricles and ventricles are in a state of diastole. There are thus three periods: (1) one of auricular systole, one-fifth; (2) one of ventricular systole, two-fifths; and (3) one of repose, two-fifths. The impulse of the apex against the wall of the chest, the moment of which is indicated by ×, occurs at the middle of the time occupied by the ventricular systole.

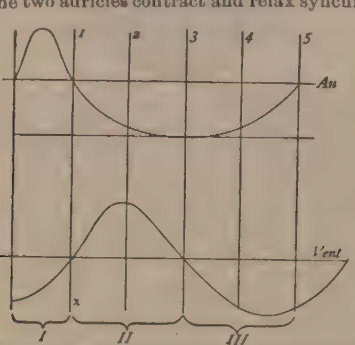

FIG. 6.—Diagram showing movements of heart.

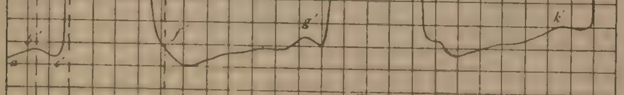

FIG. 7.—Tracings from the heart of a horse, by Chauveau and Marey. The upper tracing is from the right auricle, the middle from the right ventricle, and the lowest from the apex of the heart. The horizontal lines represent time, and the vertical amount of pressure. The vertical dotted lines mark coincident points in the three movements. The breadth of one of the small squares represents one-tenth of a second.

In 1861 Chauveau and Marey obtained a direct record of the movements of the heart of a horse, determined the duration of the events happening in the heart, and measured the endocardiac pressure by an instrument termed a cardiac sound. When the sound was introduced into the right auricle and right ventricle—the animal being anæsthetized—the tracings shown in Fig. 7 were obtained. From this diagram we learn the following facts: (1) The auricular contraction is less sudden than the ventricular, as is indicated by the line *ab* being more oblique than the line *c'*, *d'*. (2) The auricular contraction lasts only for a very short time, as the curve almost immediately begins to descend, whereas the ventricle remains contracted for a considerable time, and then slowly relaxes. (3) The time of the contraction of the auricle and that of its relaxation are about equal, but the time of the relaxation of the ventricle is nearly twice as long as that of its contraction; the movements of the auricle are thus uniform and wave-like, whilst those of the ventricle have more of a spasmodic character. (4) The auricular movement (*ab*, *a'b'*, *a''b''*, *g*, *g'*, *g''*) precedes the ventricular, and the latter coincides with the impulse of the apex against the wall of the chest, as is seen from the second vertical dotted line. (5) The contraction of the auricle, by forcing blood onwards, affects the pressure for an instant in the ventricle, as is indicated by the little elevation immediately before the ventricular contraction. (6) During the period of contraction of the ventricle there are oscillations of pressure affecting both the auricle and the ventricle; these are indicated by the little waves *d*, *e*, *f*, *d'*, *e'*, *f'*, *d''*, *e''* and *f''*; similar waves are seen at *h*, *i*, *h'*, *i'*, *h''* and *i''*. The letters *k*, *e*, *k'*, *e'*, and *k''*, *e''* represent a third set of waves.

Sketch of cardiac revolution.

With these facts in view, we may now describe the phenomena which happen in a complete cardiac revolution. Suppose the blood to be pouring from the venæ cavæ and the pulmonary veins into the two auricles. At that moment the auricles are passing into a state of complete diastole, and their cavity is increased by the funnel-shaped aperture at the auriculo-ventricular openings formed by the segments of the valves guarding these orifices. The distension of the auricles is due partly to the pressure in the venæ cavæ and pulmonary veins being less than in the interior of the auricles and partly to the aspirating action of the thorax during inspiration, sucking, as it were, the blood from the veins outside the chest to those inside the chest, and thus favoring the flow of blood to the heart. During this time both ventricles are filling with blood, the auriculo-ventricular orifices being open. When the distension of the auricles is complete (which happens before the distension of the ventricles, because the capacity of the auricles is much smaller than that of the ventricles), the auricular systole commences by the contraction and emptying of the auricular appendix towards the general cavity of the auricle, and by the mouths of the veins becoming narrowed by contraction of the circular fibres in their coats. These rhythmic movements are propagated quickly over the auricular walls, causing them to contract simultaneously towards the auriculo-ventricular orifices. The contracting wall forces the blood chiefly in the direction of least resistance, that is, into the ventricle, which at the same time is only partially full of blood, and is passing into a state of complete relaxation. The pressure in the veins, aided by their rhythmic contraction at the commencement of the auricular systole, is sufficient to prevent the blood from passing backwards, except to a very slight extent; but there is a momentary arrest of the flow in the large venous trunks. Thus the auricles act, not only as passive reservoirs for the blood in its passage from the veins to the auricles, but as rhythmic cavities tending to keep up a mean pressure in the veins, in diminishing by their extensibility the pressure which tends to increase during the ventricular systole, and in increasing the pressure by their contraction at a time when the venous pressure would diminish, that is, towards the close of the ventricular diastole. Both auricles and ventricles exercise, during their diastole, a certain aspirating or sucking action, like that seen during the relaxation of a compressed india-rubber bag; but this force is very feeble in the case of the heart.

---

[1] See Marey, *La Méthode Graphique, ut supra.*

The amount of blood discharged into the ventricles (already partially filled during the relaxation of the auricles) by the auricular systole is sufficient to fill their cavities, and consequently the ventricular systole immediately follows the contraction of the auricles. During the inflow of blood from auricles to ventricles the auriculo-ventricular valves are floated upwards into a more or less horizontal position, and the assumption of this position is further aided by the contraction of the longitudinal muscular fibres that pass from the auricles into the cusps of the valves. When the ventricular walls contract, the margins of the auriculo-ventricular valves are closely pressed together, and the cusps are kept from being folded backwards into the auricle by the simultaneous contraction of the musculi papillares pulling on the chordæ tendineæ which are affixed to the ventricular aspect of the valves. The close apposition of the cusps is also increased, even along their margins, by the arrangement that the chordæ tendineæ of one papillary muscle always pass to the adjoining edges of two cusps. Thus the valves, tricuspid on the right side and mitral on the left, are tightly closed and the blood cannot regurgitate into the auricles. The blood, thus compressed, can only pass into the pulmonary artery from the right ventricle and into the aorta from the left. The positive pressure in the ventricles is at its maximum at the beginning of their contraction; during the contraction it diminishes; and at the close of the systole (Marey), or in the diastole immediately thereafter (Goltz and Gaule), or even, according to Moens, shortly before the systole has reached its height, the pressure may even become negative. Moens "explains this aspiration as being due to the formation of an empty space in the ventricle caused by the energetic expulsion of the blood through the aorta and pulmonary artery" (Landois and Stirling). As the blood passes from the ventricles into the pulmonary artery and aorta, the segments of the sigmoid valves are forced open and stretched across the dilatations or sinuses behind each cusp, without being actually pressed against the walls of the vessels; and, as both the pulmonary artery and the aorta contained a certain amount of blood before, the pressure in these vessels is increased, and the walls of both yield to a considerable extent. As already stated, the ventricle continues in the contracted state for a brief space of time, and then it relaxes. Simultaneously with the commencement of relaxation, the auriculo-ventricular orifices open, thus permitting the passage of blood from the auricles; and at the same time the elastic walls of the aorta and pulmonary arteries recoil and force a portion of the blood backwards towards the cavities of the ventricles, in which as they are passing into diastole, the pressure is much less than in the vessels. This blood, however, by filling the sinuses of Valsalva and the crescentic pouches of the sigmoid valves, closes these latter, and thus prevents any blood from passing into the ventricles. From the end of the ventricular contraction to the moment when the auricles are again full, all the cavities of the heart are in a condition of dilatation and the cavities are filling with blood. This is the period of the pause, during which the heart may be supposed to be in a state of rest.

Change in shape of heart.

When one watches an actively beating heart exposed in an anæsthetized animal, the movements are so tumultuous and rapid that the eye cannot follow them so as to convey to the mind a correct conception of the rapid changes in form. Owing to this our notions of such changes have been derived chiefly from an inspection of the heart after death. Recent ingenious investigations by Ludwig and Hesse have shown that the post-mortem form is not the natural shape of the living heart either in diastole or in systole, but such as is shown, for example, in Fig. 8.

Apex beat.

The apex beat or shock of the heart is synchronous with the systole, and is caused normally by the apex of the ventricle pressing more firmly against the chest wall, from which it is separated when the heart is at rest by the thin margin of the lung. At the time of ventricular systole, as already seen, the heart, instead of being an oblique cone having an elliptical base, as in rest, becomes more like a regular cone, having a circular base. When contraction occurs, the apex is carried from below and behind, upwards and forwards, and is forced into the intercostal space, and at the same time the ventricular portion twists on its long axis from left to right, so as to expose partially the left ventricle. It is the twisting motion that gives the shock or impulse, and it is caused chiefly by the contraction of the oblique fibres in the ventricles which lift up the apex; it is also assisted by the slightly spiral arrangement of the aorta and pulmonary artery. Some have supposed that the movement is partly due to the recoil of the ventricles after discharging their blood (like that of an exploded gun), causing the apex to go in the opposite direction, downwards and outwards; others have held that the discharge of blood into the pulmonary artery and aorta causes an elongation of these vessels, whereby the apex is pushed downwards and forwards. Both of these mechanisms, however, must have only a slight effect, as the cardiac impulse occurs even when from hæmorrhage the pulsating heart is practically empty.

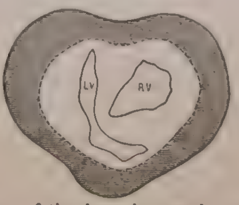

FIG. 8.—Projection of the base in systole and diastole: *R V*, right ventricle; *L V*, left ventricle.

Cardiographic tracings.

To obtain a tracing of the apex beat an instrument termed the cardiograph is employed, various forms of which are figured in Landois and Stirling's *Human Physiology*, vol. i. p. 89 *sq.* Figs. 9 and 10 are examples of tracings obtained by this instrument. From the latter figure we learn the subjoined information. The time of the pause and the contraction of the auricle are represented by *ab*, and it is evident that the latter phenomenon causes the apex of the heart to move towards the intercostal space. The portion *bc* corresponds to the contraction of the ventricles and is synchronous with the first sound. The curve then rapidly falls as the ventricles relax, and during the descent there are two elevations, *d* and *e*, synchronous with the second sound. As already stated, when the ventricles relax, the blood in the aorta and pulmonary artery, driven backwards by the elastic recoil of the walls of these vessels, closes the semilunar valves. This shock is propagated to the apex of the ventricles and thus causes a vibration of the intercostal space. The elevation *d* is synchronous with the closure of the aortic valves and *e* with that of the pulmonary valves; it is also apparent that these valves are not closed at the same moment, but are separated in time by .05 to .09 of a second,—an effect due, as already explained, to the greater blood pressure in the aorta than in the pulmonary artery. Finally, *ef* corresponds to the remaining part of the ventricular diastole.

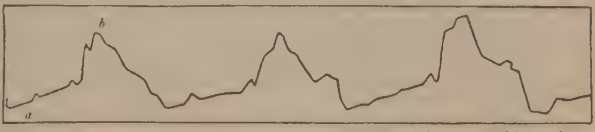

FIG. 9.—Tracing of cardiac pulsations of a healthy man (Marey.)

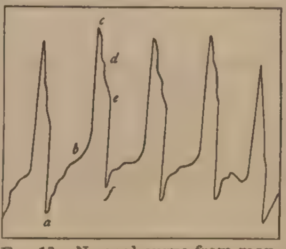

FIG. 10.—Normal curve from man. (Landois.)

Nature of heart's contraction.

Much discussion has taken place as to whether the contraction of the heart is to be regarded as a simple contraction, like the "twitch" of a muscle obtained by a single stimulation, or as a tetanic contraction, like cramp, such as is caused by the application of a number of stimuli in rapid succession. It is true that many of the phenomena of a cardiac contraction resemble those of a skeletal muscle: thus, fatigue diminishes the amplitude and increases the duration of the contraction; and the effects of changes of temperature are similar. The period of latent stimulation of a cardiac muscle (one-third of a second) is much longer than that of skeletal muscle (one-hundredth of a second). The systolic contraction, as regards duration, is more like a tetanic spasm than a twitch, being from eight to ten times longer. The electrical phenomena, on the other hand, resemble those of a twitch more than those of tetanus. Thus, when the heart is examined with a sensitive galvanometer, and with the aid of the appliances described under PHYSIOLOGY (vol. xix. p. 29 *sq.*), there is a "negative variation" with each beat. The fact appears to be that just as the heart muscle shows histological characters intermediate between voluntary striated muscle and involuntary non-striated muscle, so it likewise shows physiological properties partaking of both.

Time of cardiac movements.

The time occupied by cardiac movements has been measured by various observers by a study of tracings obtained from the impulse of the apex of the heart against the wall of the chest, as recorded by the cardiograph. If the velocity of the surface on which the tracing is obtained be known, and if a correct interpretation is given of the causes of the various parts of the curve, it is not difficult to determine approximately the time occupied by the phases of a cardiac revolution. Rollett gives the following results in fractions of a second as determined by Landois (Hermann, *Handb. d. Physiol.*, vol. iv. p. 157).

Events in the Heart.	Rate of Heart-Beat per Minute.				
	55	55	74.2	109.7	113.1
	Duration of Phases.				
1. From beginning of pause to end of auricular contraction	.563	.584	.494	.213	.247
2. Contraction of ventricle	.243	.274	.079	.066	.057
3. Relaxation of ventricle to closure of semilunar valves	.066	.072	.144	.194	.133
4. From close of pulmonary valves to beginning of pause	.259	.200	.092	.090	.103
5. Between 1st and 2d sounds	.309	.346	.223	.244	.190
6. Between 2d sound and next 1st sound	.822	.784	.586	.303	.394
7. Time from 1 to 4 inclusive (complete cardiac revolution)	1.133	1.133	.809	.547	.539
8. From closure of aortic valves to closure of pulmonary valves	....	....	.078	.100	.057

Frequency of cardiac pulsations.

In the adult man cardiac pulsations occur at the rate of 65 to 75 per minute. There is a certain relation between the amount of blood in the circulation and the frequency of heart-beats. Thus, in the animal series, as the beats of the heart increase in frequency the quantity of blood which passes per minute in one kilogramme (2.2 ℔) of body weight also increases, as is shown in the following table by Vierordt:

	Quantity of Blood per Minute and per Kilogramme of Body Weight.	Number of Pulsations per Minute.
Horse	152 grammes	55
Man	207 "	72
Dog	272 "	96
Rabbit	620 "	220
Guinea-pig	892 "	320

Quantity of blood in heart.

It has been determined, both by direct measurement and by calculation based on the velocity of the blood in the aorta and the transverse section of the orifice of that vessel, that from a heart of average size each left ventricular systole ejects about 180 grammes (6.35 oz.). This is the figure usually given, but it must be regarded merely as approximative. The amount may vary even in the same individual according to the state of vigor of the muscular walls of the organ.

Sounds of heart.

When the ear is applied over the cardiac region of the chest of a healthy man two sounds are heard, the one with greatest intensity over the apex and the other over the base of the heart. The dull long sound heard over the apex has received several names, such as the first, the long, the inferior, and the systolic sound, whilst that over the base,—clearer, sharper, shorter, higher,—has been called the second, the short, the superior, the diastolic sound. Suppose the heart sounds to be expressed by the syllables *lupp dupp;* then the accent is on lupp (the first sound) when the stethoscope is over the apex—thus, lúpp dupp, lúpp dupp—and on dupp (the second sound) when over the base—thus, lupp dúpp, lupp dúpp. There is a pause between the second sound and the next succeeding first sound, and a much shorter pause (almost inappreciable) between the first and second sounds: thus—

At apex—lúpp dupp (pause), lúpp dupp (pause), lúpp dupp.
At base—lupp dúpp (pause), lupp dúpp (pause), lupp dúpp.

These relations are well seen in Fig. 11. Dr. Walshe states that, if the cardiac cycle be divided into tenths, the first sound will last four-tenths, the short pause one-tenth, the second sound two-tenths, and the long pause three-tenths. There has been considerable difference of opinion as to the cause of the first sound. Some have supposed it to be due to vibrations of the auriculo-ventricular valves; others believe that it is muscular, and due to the contraction of the ventricles; not a few have attributed it to movements of the blood through the aortic and pulmonary orifices; whilst yet others have thought that it might be the result of a fusion of these effects. It is certainly not due to the shock of the heart against the chest wall, as it has been heard after removal of the heart from the chest. The most likely view is that it is a muscular sound, varying in quality from the ordinary sound of a contracting muscle in accordance with the peculiar arrangement of the cardiac fibres, and that this sound is modified by the vibrations of the tense auriculo-ventricular valves. The fact that the sound has been heard from an excised heart still pulsating but empty of blood strongly supports this view; and there is further the pathological evidence that in cases where the muscular walls have been much weakened by fatty changes (as in the advanced stages of typhus, fatty degeneration, etc.) the first sound may disappear. No doubt exists as to the cause of the second sound; it is produced by the sudden sharp closure of the sigmoid valves. As already mentioned, the aortic and pulmonary valves do not close absolutely simultaneously.

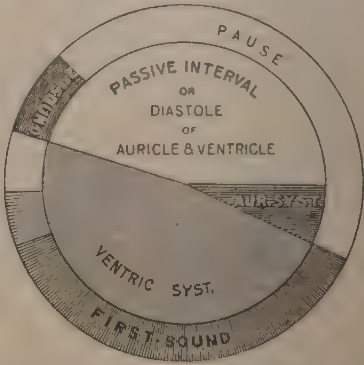

FIG. 11.—Scheme of a cardiac cycle after Gairdner and Sharpey. The inner circle shows what events occur in the heart, and the outer the relation of the sounds and silences to these events.

For practical purposes it is important to bear in mind what is happening in the heart whilst one listens to its sounds. With the first sound we have (1) contraction of the ventricles, (2) closure of the auriculo-ventricular valves, (3) rushing of the blood into the aortic and pulmonary artery, (4) impulse of the apex against the chest, and (5) filling of the auricles. With the second sound we have (1) closure of the semilunar valves from the elastic recoil of the aorta and pulmonary artery, (2) relaxation of the ventricular walls, (3) opening of the auriculo-ventricular valves so as to allow the passage of blood from auricle to ventricle, and (4) diminished pressure of apex against chest wall. With the long pause there are (1) gradual refilling of the ventricle from the auricle and (2) contraction of the auricle so as to entirely fill the ventricle. The sound of the tricuspid valve is loudest at the junction of the lower right costal cartilage with the sternum, of the mitral at the apex beat, of the semilunar valves at the aortic orifice in the direction of the aorta, where it is nearest to the surface, at the second right costal cartilage, and of the valves at the pulmonary orifice over the third left costal cartilage, to the left and external to the margin of the sternum.

For an account of the mechanical work performed by the heart, see NUTRITION, vol. xvii. p. 705.

Nutrition of heart.

The heart is directly nourished by the blood flowing through its cavities in some of the lower Vertebrates, as the frog; but in the hearts of larger animals, in which nutritional changes must be actively carried on, there is a special arrangement of vessels or cardiac circulation. The coronary arteries originate at the aortic orifice in the region of the sinus of Valsalva, rather above the upper border of the semilunar valves, so that when the ventricle contracts the mouths of these arteries are not covered by the segments of the valves. The branches of the coronary arteries, after dividing and again dividing, penetrate the muscular substance and end in a rich plexus of capillaries, which carry arterial blood to the structure of the heart. From these the radicles of the cardiac veins originate, and these veins carry the blood, now rendered venous, into the right auricle by the larger anterior cardiac veins and by numerous small veins constituting the foramina of Thebesius or the *venæ minimæ cordis.* The coronary vein is dilated before entering the auricle, forming the coronary sinus, and at the junction of the vein with the dilated portion there is a valve consisting of one or two segments. Other veins enter the coronary sinus, each having a valve. These valves serve two purposes: (1) they interrupt the flow of blood during the contraction of the right auricle, preventing regurgitation and venous congestion of the wall of the heart, and (2), as the valves open towards the right auricle, they prevent the backward flow of blood during contraction of the ventricles and favor its onward flow, and thus the stream of blood is accelerated, as in the veins of a contracting muscle. The blood is sent through the cardiac circulation by the systole of the ventricle, and not, as was advocated by Brücke, during its diastole. Heart disease in advanced life, when the coronary arteries are often thickened and their calibre much diminished by sclerosis, may be shown by attacks of palpitation, weakness of the heart, altered rhythm, breathlessness, congestions, pulmonary œdema, hæmorrhage, and faintings,—all due to interference with the normal nutrition of the heart.

Lymphatics of heart.

In an organ so active as the heart the lymphatic system is necessarily largely developed. These vessels, acting like drainage tubes for carrying away waste products, are found in great numbers beneath both the pericardium and the endocardium, and throughout the muscular tissue. Amongst the muscular fibres there are numerous lacunæ or spaces lined by endothelial cells, which are the origins of the lymphatics. The lymph is carried into lymphatic glands between the aorta and the trachea, and ultimately finds its way into the right innominate vein and the thoracic duct.

Persistence of cardiac movement.

It has been known from early times that the heart will continue to beat after its removal from the body. This is more especially the case with the hearts of cold-blooded animals. The frog's heart may continue to pulsate for two and a half days, whilst that of a rabbit will do so only for a period of from three to thirty minutes. The average duration of the beats of the warm-blooded heart is said to be eleven minutes. The right auricular appendix, which beats longest, has been observed to pulsate in the rabbit fifteen hours after death, in the mouse forty-six, and in the dog ninety-six hours. After the heart has ceased beating, it may again be caused to contract by direct stimulation or by heat. The injection of arterial blood into the coronary vessels will restore excitability in the Mammalian heart after it has ceased to beat (Ludwig).

Cardiopneumatic movement.

If a wide glass tube filled with smoke be inserted into one nostril, while the other nostril and the mouth are closed, the smoke will be seen to move with each pulsation of the heart (Stirling). This phenomenon has been studied by Ceradini and Landois. It is explained by the fact that when the heart contracts it occupies less space in the chest, and consequently, if the glottis be open, air will be drawn into the lungs. The reverse will happen during the diastole.

The heart and lungs being contained in an air-tight cavity, the chest or thorax, it is evident that the increase and decrease in the size of the chest during inspiration and expiration must affect the amount of pressure on the outer surface of the heart, and consequently its movements. When an inspiration is made by the descent of the diaphragm and the elevation of the ribs, the lungs expand; there is then less pressure on the outer surface of the heart and the heart is in a state of distension in diastole. In consequence also of the removal of pressure during inspiration from the great veins entering the chest and reaching the right side of the heart, the flow of venous blood towards the heart is favored. These effects are more marked if after a deep expiration the glottis be closed, so as to prevent air entering the lungs, and if then the chest be dilated by a powerful inspiratory effort (J. Müller). This causes a dilatation of the heart, and venous blood flows freely into the right side; this sends it on to the lungs, causing them to become engorged, whilst at the same time the dilated left side of the heart is unable to send out a sufficient amount of blood into the arterial system. The pulse in such conditions may disappear, and there is an intense feeling of distress. On the other hand, expiration increases the pressure on the outer surface of the heart and of the great veins; only a small amount of blood flows into the right side; the heart is contracted; the systole is small; and the pulse is reduced in volume. This condition is intensified in what is termed Valsalva's experiment, in which after a deep inspiration the glottis is closed and a powerful expiratory effort is made. When this is done, the flow of venous blood into the heart is interrupted, the veins in the face and neck swell, and the blood is forced out of the compressed lungs into the left side of the heart, which throws it into the arterial circulation. The pulse and heart sounds disappear and there is the risk of syncope or fainting. Both these experiments, Müller's and Valsalva's, are dangerous and should not be often repeated. They are extreme conditions of the normal state of things, in which inspiration favors the flow of blood into the heart and the dilatation of the heart, whilst expiration has the opposite effect; and they also explain the mechanism by which air may be sucked into the veins from wounds in the neck or armpit. This is most likely to occur during inspiration, and when it does occur speedy death is the result.

Innervation of heart.

In treating of the innervation of the heart we have to consider (1) the influence of the great nerves connecting the heart with the central nervous organs, or what may be termed the *extrinsic nervous mechanism,* and (2) the nervous arrangements in the heart itself, or the *intrinsic nervous mechanism.* (1) The extrinsic arrangement, consisting of the nerves given off by the cardiac plexuses derived partly from the cerebro-spinal and partly from the sympathetic system, have been investigated chiefly in the larger animals, such as the tortoise, rabbit, and dog, and the general results have been described under PHYSIOLOGY (vol. xix. p. 21 *sq.*). They may be briefly summarized as follows: (*a*) there are fibres in the vagus nerve exercising a controlling or inhibitory action on the heart, and these fibres originate in the medulla oblongata; (*β*) the sympathetic nerve supplies accelerating fibres to the heart, and these fibres originate in the cerebro-spinal system. (2) The intrinsic arrangements have been investigated more especially in the heart of the frog, a view of which is given in Figs. 12 and 13. It will be seen that the frog's heart possesses two auricles, communicating by a foramen in the septum, and a single ventricle. The venous blood from the body is poured in the first instance, not into the right auricle, but into a cavity called the *sinus venosus,* which communicates with the right auricle. The left auricle receives the arterial blood from the lungs by the pulmonary veins. Both auricles empty into the common ventricle, which contains therefore a mixture of arterial and venous blood, and when the ventricle contracts some of this blood is again sent to the lungs, whilst the remainder passes into a dilatation at the commencement of the arterial system, called the *bulbus arteriosus,* and thence into the aorta.

Extrinsic.

Intrinsic.

After the heart of a decapitated frog has been removed

Results of experiment.

from its body, and so from the influence of the great nervous centres, rhythmical movements may continue for some time independently of those centres. If the apex of the heart be then cut off, it will remain motionless, whilst the larger part will still beat rhythmically. Successive slices may be removed from the larger portion without affecting rhythmical contraction, until a section is made through the auriculo-ventricular groove, when the ventricular portion of the heart ceases to beat. If the motionless apex, or the separate portions rendered motionless by the above procedure, be mechanically irritated, a single contraction, not a series of rhythmic contractions, follows.

Experiment of Descartes.

When the ventricle is separated from the rest of the heart by a ligature, or by concision at the level of the auriculo-ventricular groove, the ventricle stops, but the auricles and the sinus go on beating. To continue the rhythmic movement of the ventricle, it is necessary to have attached to it a small portion of the auricular part of the heart, especially the lower margin of the septum. It would, therefore, appear that impulses pass from this auricular portion into the ventricular and cause the latter to pulsate.

Experiment of Stannius.

If the sinus venosus be separated from the auricles by incision or ligature, the veins and the sinus continue to beat, whilst the auricles and ventricles are arrested in diastole. Suppose another incision be made through the auriculo-ventricular groove, the ventricle frequently begins to beat, but the auricles remain in diastole. It is also observed in these circumstances that the ventricle beats more slowly than under normal conditions. Although the rhythmical contractions of the heart are influenced by the nervous arrangements, it cannot be said that ganglionic nerve cells and nerve fibres are a necessary part of the mechanism. It has been shown by Engelmann that, if the ventricle of a frog's heart be cut into two or more strips in a zigzag manner, so that the parts still remain connected with each other by muscular tissue, the strips still beat in a regular progressive manner, provided one strip is caused to contract.

The Action of the Bloodvessels.

Flow of fluids through tubes.

It is evident that a general study of the flow of fluids through tubes ought to precede that of the flow of the blood through the complicated system of tubes constituting the arteries, capillaries, and veins. In this place, however, it is necessary to allude only to those facts in hydraulics which have a special bearing on the phenomena of the circulation (comp. HYDROMECHANICS, vol. xii. pp. 486 *sq.*). When a stream of water is transmitted intermittently by the strokes of a pump through a long elastic tube, formed, say, of india-rubber, the fluid does not issue from the other end in a series of jets, which would be the case if the tube were rigid, but it flows continuously, because during the pause between the successive strokes the outflow still continues. Consequently a continuous flow is kept up in elastic tubes when the time between two strokes is shorter than the duration of the outflow after the first stroke. If the finger be placed on any part of such a tube, and more especially near the pump, an expansion and relaxation will be felt with each stroke. Further, if the right fore-finger be placed over the tube near the pump, and the left forefinger over a more distant portion, a stronger impulse will be felt with the right than with the left finger. Thus a wave is transmitted along the tube, diminishing in amplitude as the distance from the pump increases. We must distinguish between the transmission of this wave (an oscillatory movement or change of form in the column of fluid) and the transmission of the current, that is, the translation of a mass of fluid along the tube. In elastic tubes the current is much slower than the transmission of the wave. The progress of the wave of oscillation may be traced graphically by an apparatus devised by Marey.[1] E. H. Weber gives the velocity of waves in elastic tubes at 36.76 feet per second, and Donders states it at 36 to 42½ feet. Increase of pressure in the tube appears to lessen the velocity of the wave. The specific gravity of the liquid also affects the velocity: thus the wave is propagated four times more slowly in mercury than in water.

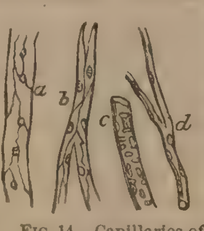

FIG. 14.—Capillaries of various size. *a*, capillary much magnified and acted on by nitrate of silver, to show that it is composed of flattened cells; *b*, a smaller vessel showing the same; *c*, a small artery or vein showing transverse or longitudinal nuclei; *d*, ultimate capillary from *pia mater* of sheep's brain.

The bloodvessels consist, as already stated, of the arteries, the capillaries, and the veins.

General structure of bloodvessels.

(*a*) The ultimate or most minute capillaries have the simplest type of structure (Fig. 14), consisting of tubes formed of a single layer of transparent, thin, nucleated, endothelial cells, joined at their margins. A perfectly fresh capillary does not show the edges of the cells, owing to the uniform refractive property of the wall of the tube. The nuclei show an internuclear plexus of fibrils. The cement substance uniting the cells is stained black by a ½ per cent. solution of nitrate of silver. Here and there minute dots or slits may be seen, which have been supposed by some to be openings (stomata or stigmata). In the transparent parts of animals, such as the web of the frog's foot, the mesentery and the lung of the frog, and the tail of a fish, the blood may be seen (Fig. 15) flowing through the capillary network from the arteries into the veins. The current is rapid in the small arteries, less rapid in the veins, and slow in the capillaries. It is also fastest in the centre of the vessel and slowest near the wall. The colorless corpuscles of the blood may be seen to pass from the centre of the stream to the margins, to adhere to the inner surface of the bloodvessel, and occasionally to pass through the coats of the more minute vessels, appearing in the surrounding tissues as migratory cells. Capillaries form networks (Fig. 15), which vary much in the size and closeness of the meshes, according to the degree of activity of the tissue elements.

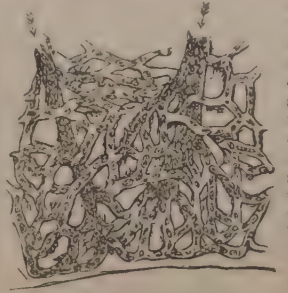

FIG. 15.—Capillary bloodvessels in web of a frog's foot, as seen with the microscope. The arrows indicate the course of the blood. (Schäfer.)

(*b*) An artery has three coats,—an inner or elastic, a middle or muscular, and an external or areolar (Fig. 16). The inner coat is formed of two layers,—one of pavement epithelium, sometimes called endothelium, and the other composed of fine elastic fibres interlacing, or of a fine membrane perforated with holes of various sizes (fenestrated membrane of Henle). In some vessels there is a thin layer of connective tissue between the epithelium and the elastic layer. The middle coat is formed of a layer of non-striated muscular fibres circularly disposed around the vessel, mixed with numerous elastic fibres connected with the perforated membrane of the inner coat. The outer coat consists of connective tissue, mixed also with elastic fibres. In the aorta there is a considerable amount of subepithelial connective tissue (Schäfer), and the elastic coat attains great thickness and strength. As a general rule, the smaller arteries show a considerable development of the muscular coat, whilst in the larger it is the elastic coat that attains the preponderance. In many of the larger arteries there are longitudinal muscular fibres at the boundary of the middle and inner coats. Whilst the circular fibres, on contracting, must narrow the calibre of the artery, the longitudinal may tend to keep the vessel open. In the external coat of the larger arteries minute vessels, *vasa vasorum*, exist for the nourishment of the tissue elements of the arterial wall.

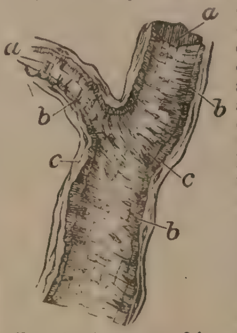

FIG. 16.—An artery of intermediate size. *a*, *a*, openings of branches and position of lining of vessel; *b*, *b*, *b*, muscular coat showing transverse nuclei; *c*, *c*, coat of areolar tissue.

(*c*) The veins have similar coats to those of an artery, with differences in detail. The elastic layer is less developed in the internal coat; the middle coat is much thinner and has less elastic tissue, but more connective tissue. Many veins have semilunar folds of the internal coat strengthened with fibrous tissue, forming valves. In some veins (iliac, femoral, umbilical) longitudinal muscular fibres are found in the inner part of the middle coat; in the inferior vena cava, hepatic veins, and portal veins these longitudinal fibres are external to the circular coat; in the superior vena cava and upper part of the inferior vena cava the circular coat is wanting; and the veins of the pia mater, brain and spinal cord, retina, bones, and the venous sinuses of the dura mater and placenta have no muscular tissue (Schäfer). Valves exist in the larger veins only, especially in those of the limbs; they are not found in the veins of the viscera, of the cranium and vertebral canal, or of the bones, nor in the umbilical vein.

---

[1] Figured in M'Kendrick's *Outlines of Physiology*, pp. 338-339.

(*d*) The arterioles and venules are the small vessels, simpler in structure than the larger above described, but containing the same elements. In the smallest veins the elastic layer has disappeared, and the muscular layer is also very thin. Sometimes the muscular layer is represented only by a single layer of contractile cells, and in such minute vessels the outer coat and elastic layer have also disappeared, so that the vessel is merely a tube composed of pavement cells with a few elongated fusiform muscular cells twisted around it. Even in the smallest vessels the following differences may be observed between arterioles and venules: "The veins are larger than the corresponding arteries; they branch at less acute angles; their muscular cells are fewer, and their epithelium cells less elongated; the elastic layer of the inner coat is always less marked, and sooner disappears" (Schäfer).

(*e*) The cavernous spaces, as existing in erectile tissues (*corpus cavernosum* of the penis), consist of the anastomosis of large veins of unequal calibre. The walls and partitions have numerous perforations; threads of delicate tissue, covered with epithelium, pass through the cavities; and the walls are strengthened by connective tissue. Similar structures connected with arteries form the carotid gland of the frog and the coccygeal gland of man.[1]

Properties of blood-vessels.

The physical properties of bloodvessels are cohesion and elasticity. The cohesion is great and the elasticity is small and perfect. The walls of bloodvessels have the property of contractility, by which alterations take place in the calibre of the vessel, and consequently in the amount of blood supplied to a part.

Arterial circulation.

Arterial Circulation.—The arterial walls are both muscular and elastic, the muscular coat predominating in the smaller, whilst the elastic coat is strong in the greater arteries. The chief function of the elasticity of the greater vessels is to transmute the unequal movement of the blood in the large arteries, caused by the intermittent action of the ventricle, into a uniform flow in the capillaries. Thus, when the ventricle contracts, it propels a certain amount of blood into the elastic aorta, which expands in all directions. On the commencement of the diastole of the ventricle the *vis a tergo* is removed; the aorta owing to its elasticity recoils, so as to close, on the one hand, the semilunar valves and, on the other, to force part of its contents into the vessels farther onwards. These, in turn, as they already contain a quantity of blood, expand, recover by an elastic recoil, and transmit the movements with diminished intensity. Thus the blood is driven along the vessels by the action (1) of the ventricular systole, and (2) of the elastic recoil of the walls of the vessels occurring during the intervals between the ventricular systole (see below). By these actions a series of movements, consisting of expansions and contractions, gradually diminishing in amplitude, pass along the arterial system from the greater to the smaller vessels, the latter becoming, as already pointed out, less and less elastic. These expansions and relaxations of the arterial wall, passing along like a wave, constitute the pulse. The pulse therefore represents merely the transmission of an undulating movement of the blood, not its progression in the vessels. The undulations of the pulse travel at the rate of $354\frac{1}{3}$ inches per second, about 30 times faster than the movement of the blood, which in the carotid artery of the horse has been estimated to travel 11.8 inches per second.

Pulse.

Sphygmograph.

The pulse can be registered graphically by means of a SPHYGMOGRAPH (*q.v.*). Vierordt constructed the first sphygmograph in 1855, substituting for a column of fluid a lever placed on the pulse, which communicated with a system of levers and thus amplified the movement. Of those subsequently devised the best form is that of Marey, invented in 1861. It consists essentially of a long lever which is moved near the fulcrum by a screw acting on a small horizontal wheel, from whose axis there projects a long, light, wooden lever. The point of the screw rests on a flat disk of steel or ivory, at the end of an elastic spring, which presses the ivory disk or pad on the artery. The lever inscribes the movements on a blackened surface, usually a strip of paper smoked in the flame of a lamp burning turpentine, carried in front of the point of the lever by clock-work. In the instrument as modified by Mahomed, Byrom Bramwell, and others there is an arrangement for adjusting the amount of pressure made on the artery by the ivory pad, so that tracings may be taken at different times from the same artery with different or with the same pressures. The tracings are "fixed" by passing them through shellac or photographic varnish.[2]

Sphygmograph or pulse tracing.

The following changes take place in an artery when it pulsates: (1) it dilates and at the same time lengthens to a small extent; (2) the pressure of the blood increases in the artery, and a feeling of hardness and resistance is experienced when the artery is compressed with the finger. These facts are illustrated in the sphygmographic curve shown diagrammatically in Fig. 17. The ascending line *ab* (line of ascent, up-stroke, or percussion stroke) corresponds to the distension of the artery produced by the systole of the left ventricle, and the descending line *bcd* to its elastic recoil; the length of the line *ad* represents the total duration of the movement, which is divided into two portions by the perpendicular line *be*. The distance *ae* measures the duration of the distension of the artery and *ed* the time of its elastic recoil. In a continuous tracing the durations of the individual pulsations are equal, and in inverse ratio to the number of pulsations in a unit of time. In a normal pulse the distension and the elastic recoil of the vessel succeed each other without interruption, so that there is no period of repose in the artery. When, however, the pressure of blood in the artery falls below a certain point, these characters disappear or are modified. Fig. 17 shows that the duration of the distension of the artery is only about one-third of that of its contraction. The rapidity and slowness of the pulse depend on the ratio of these periods. The pulse is quick when the duration of the arterial distension diminishes, and slow when it increases. The line *ab* becomes less oblique and more nearly vertical, in proportion as the time of the distension is short, quick, and nearly instantaneous. The rapidity of the pulse is increased by quick action of the heart, considerable power of yielding in the arterial walls, easy afflux of blood owing to dilatation of smaller vessels, and nearness to the heart. The term *quickness* has reference to a single pulse-beat, and *frequency* to the number of beats in a given time, say, one minute. The line *bcd* is always more oblique than *ab*, and in careful tracings it presents several elevations or notches (see Fig. 18). If we refer the different portions of the curve to their origin the result is as follows: (1) the up-stroke corresponds to the systole of the left ventricle, opening the aortic valves, pouring the blood into the arteries, and distending them; (2) the down-stroke represents the time during which the blood is flowing out of the arteries at their periphery into the capillaries; (3) the larger wave in the descent, *i.e.*, the dicrotic, recoil, or aortic systolic wave, represents the time of the closure of the aortic valves; (4) the predicrotic, first tidal, or second ventricular systolic wave occurs after the first systolic wave and during the ventricular contraction (Byrom Bramwell). In many pulse-tracings there are still smaller secondary waves, due to elastic vibrations of the wall of the vessel. The three factors causing an arterial pulsation are (1) the more or less energetic contraction of the ventricle, (2) the quantity and pressure of the blood, and (3) the elastic and contractile properties of the arterial wall. If these factors be in any way modified there will be a corresponding modification in the physical characters of the pulse. The character of a pulse-tracing is affected by the amount of pressure applied to the artery. With a light pressure the dicrotic wave is relatively less; with a moderate pressure ($3\frac{1}{2}$ to 7 oz.) it is well marked, whilst the curve is lower; and with greater pressure it is again reduced. With $7\frac{3}{4}$ to $10\frac{1}{2}$ oz. pressure small secondary waves appear before the dicrotic.

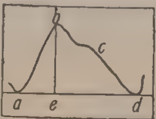

FIG. 17.—Diagram of a sphygmographic tracing.

Physiological characters of pulse.

The normal pulse-rate in man is about 72 per minute, in woman about 80 per minute; but in some individuals a state of health is consistent with a pulse-rate as rapid as 100 or as slow as 50 beats per minute. The pulse-rate is influenced by the undermentioned factors. (1) *Age:* a newly-born child, 130 to 140 beats per minute; 1 year, 120 to 130; 2 years, 105; 3 years, 100; 4 years, 97; 5 years, 94 to 90;

---

[1] Prof. Hyrtl has made remarkable demonstrations of the vascular system by means of corrosion. After injecting organs or a fœtus with a preparation of rubber and wax, the parenchyma is corroded by means of acid, and the venous and arterial systems are seen in their relation to each other in appropriate colors. His original collection is in the museum of the College of Physicians of Philadelphia, Pa.—Hyrtl, *Die Corrosion-Anatomie*, Vienna, 1873.—AM. ED.]

[2] [Pond's instrument is one quite generally used in the U. S.—AM. ED.]

10 years, about 90; 10 to 15 years, 78; 15 to 50 years, 70; 60 years, 74; 80 years, 79; 80 to 90 years, over 80. (2) *Length of body:* Czarnecki, Volkmann, and Rameaux have shown that as the height increases the pulse slows. (3) *Bodily states:* active muscular exercise, increased blood-pressure, active digestion, pain, nervous excitement, extreme debility quicken the pulse. (4) *Temperature:* increase of temperature quickens the pulse. An increase of 1° above 98° Fahr. is associated with an increase of 10 beats per minute; thus, at 89° Fahr. the pulse-rate will be 60 per minute; at 99°, 70; at 100°, 80; at 101°, 90; at 102°, 100; at 103°, 110; at 104°, 120; at 105°, 130; and at 106°, 140 (Aitken). (5) *Posture:* the pulse is more frequent when one stands than when one sits, and still slower when one lies down. (6) *Sensory impressions:* music is said by Dogiel to quicken the pulse. (7) *Pressure:* increased barometric pressure slows the pulse. (8) *Diurnal rhythm:* 3 to 6 A.M., 61 beats; 8 to 11.30 A.M., 74; towards 2 P.M., a decrease; towards 3 (at dinner-time) another rise, which goes on until 6 to 8 P.M., when it may be 70; towards midnight, 54; a rise again towards 2 A.M., when it soon falls again, and afterwards rises, as before, towards 3 A.M. (Landois and Stirling).

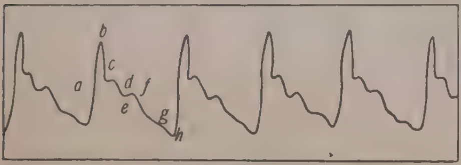

FIG. 18.—Sphygmogram of radial artery; pressure 2 oz. Each part of the curve between the base of one up-stroke and the base of the next corresponds to a beat of the heart, so that this figure shows five heart-beats and part of a sixth; *ab*, the ascent; *b*, apex of up-stroke; *b* to *h*, the descent, with an elevation *d*, the first tidal or predicrotic wave; *e*, aortic notch; *f*, a second elevation, the dicrotic wave; *g*, a slight curve, sometimes called the second tidal wave. (Landois and Stirling.)

Colin gives the following pulse-rates in various animals: elephant, 25 to 28 beats per minute; camel, 28 to 32; giraffe, 66; horse, 36 to 40; ox, 45 to 50; tapir, 44; ass, 46 to 50; pig, 70 to 80; lion, 40; lioness, 68; tiger, 74; sheep, 70 to 80; goat, 70 to 80; leopard, 60; wolf (female), 96; hyæna, 55; dog, 90 to 100; cat, 120 to 140; rabbit, 120 to 150; mouse, 120; goose, 110; pigeon, 136; hen, 140; snake, 24; carp, 20; frog, 80; salamander, 77.

Strength of pulse.

Tension.

Volume.

A pulse is said to be strong or weak according to the weight it is able to raise. The strength is usually estimated by pressing the finger on the artery until the pulse-beat beyond the point of pressure disappears. The pulse is said to be hard or soft according to the degree of resistance experienced. In feeling the pulse it is important to notice whether the tension is great during the distension of the vessel, or whether it is hard during the intervals between the pulse-beats as well as during the beats themselves. On the other hand, it may be soft in these intervals in consequence of the semilunar valves at the aorta not closing perfectly (aortic incompetence), thus allowing the blood partially to flow back into the ventricle. This softness and the feeling of sudden collapse of the arterial wall are the pulse characteristics of unfilled arteries. A pulse may be large in volume, as where a large amount of blood is thrown into the aorta, owing to hypertrophy of the left ventricle, or it may be small and thready when a small quantity of blood passes into the aorta, either owing to a diminished total amount of blood, or from constriction of the aortic orifice (aortic stenosis), or from disease of the mitral valve allowing the blood to regurgitate into the left auricle, or when the ventricle contracts feebly.

Velocity of pulse-wave.

The pulse becomes later and later in time as we recede from the heart. Czermak estimated the delay as follows: carotid pulse, after the cardiac beat, .087 second; radial, .159 second; posterior tibial, .193 second. By placing delicate tambours or electromagnetic sphygmographs at different points of the circulation and recording the movements on a rapidly moving surface, E. H. Weber found the velocity of the pulse-wave to be 30.31 feet per second; Garrod found it to be from 29.52 to 35.43 feet per second; Crashey determined it at 27.89 feet per second; and Moens at 27.23. In the arteries of the upper limb it is stated to be 30.84 and in those of the lower limb 31.82 feet per second. The wave-length is obtained "by multiplying the duration of the inflow of blood into the aorta = .08 to .09 second by the velocity of the pulse-wave." This would give the wave-length at 2.46 feet.

Influence of respiration on pulse.

As already pointed out, inspiration favors the flow of blood into the veins and retards the flow in the arteries, whilst expiration has the reverse effect. The tension of the arteries during inspiration is therefore less than in expiration, and this affects the form of the pulse-curve, as is seen in Fig. 19. (1) "The greater distension of the arteries during expiration causes all the parts of the curve occurring during this phase to be higher; (2) the line of ascent is heightened during expiration, because the expiratory thoracic movement helps to increase the force of the expiratory wave; (3) owing to increase of the pressure the dicrotic wave must be less during expiration; and (4) for the same reason the elastic elevations (secondary waves) are more distinct and occur higher in the curve near its apex" (Landois and Stirling, *op. cit.*). See also p. 112 above.

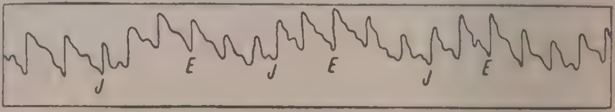

FIG. 19.—Sphygmographic tracing showing influence of respiration on pulse. J, during inspiration; E, during expiration. (Riegel.)

Contractility of arteries.

Non-striated muscle, as has been already stated, exists to a considerable amount in the walls of the smaller arteries, and the calibre of these vessels may consequently be changed by the activity of the contractile coat. The contractility of vessels may appear under two forms: (1) as rythmical contractions, such as have been seen in the vessels of a rabbit's ear or in a bat's wing, which are independent both of the pulse and of respiratory movements; and (2) as persistent contractions, under the influence of the nervous system, which play an important part in the distribution of the blood. The amount of contraction of an artery will affect the pressure of the blood in its interior; it will accelerate or retard the rapidity of the blood current; and it will regulate the supply of blood to the capillary area to which the vessel is distributed. By such arrangements, also, the distribution of blood to various organs is regulated, thus establishing what has been termed a *balance of local circulations.* For example, if the vessels in one organ remain permanently contracted, whilst those in a neighboring organ are dilated, more blood will pass to the latter than to the former, and some end of physiological importance may be served. Thus physiological correlations may be established between the cerebral and thyroid circulations, the gastro-hepatic and the splenic circulations, and the distribution of blood in the lower extremities as related to the abdominal organs.

Arterial sounds.

If a stethoscope be placed over a large artery, a murmur, sound, or bruit will be heard, caused by the blood rushing through the vessel narrowed by the pressure of the instrument. The fluid escapes into a wider portion of the vessel beyond the point of pressure, and the sound is caused by the particles of fluid there being thrown into rapid vibration, not by vibrations of the wall of the vessel. Such sounds are favored by a certain degree of elasticity in the walls of the vessel, by diminished peripheral resistance allowing the blood to flow away freely, and by a considerable difference of the pressure in the narrow and wide parts of the tube. They are always heard over an aneurism, when the arterial tube is dilated, and when pressure is applied to a large vessel. The placental souffle or bruit heard during pregnancy is a sound of this kind, arising from pressure on the widely dilated uterine arteries. In cases of insufficient aortic valves a double blowing murmur may be heard, the first being due to the rush of blood into the vessel caused by the ventricular contraction, and the second by the flowing back of the blood into the heart during diastole. Comp. p. 116 below.

Capillary circulation.

Capillary Circulation.—The circulation in the capillaries may be readily studied by placing under the microscope any transparent membrane containing vessels, such as the web of a frog's foot, the mesentery, lung, or tongue of a frog, the tail of a fish or a tadpole, the wing of a bat, the third eyelid of the pigeon or fowl, the liver of a frog or a newt, the mucous membrane of the inner surface of the human lip, or the conjunctiva of the eyeballs and eyelids. Under favorable conditions the following phenomena may clearly be noticed. (1) The diameter of the finest capillaries is such as to permit the passage of corpuscles in single file only, and it may vary from $\frac{1}{5000}$ to $\frac{1}{12000}$ of an inch. (2) The average length is about $\frac{1}{50}$ of an inch. (3) The number varies according to the degree of activity of the tissue, being numerous where nutritive processes are active, as in the liver and muscles. (4) They form networks or anastomoses, the form and arrangement of which are determined by the tissue elements. (5) In the smaller arterioles and venules, and in the capillaries, the current is continuous and there is no pulse. Owing to the elasticity of the larger vessels the intermittent movement of the blood caused by each ventricular contraction is in the capillaries transformed into a continuous flow. (6) In some of the larger vessels the current is more rapid than in others of equal calibre: that is to say, it is more rapid in small arteries than in small veins. (7) The current appears to have a uniform velocity in all ultimate capillaries of the same size. (8) Sometimes a slight acceleration of the rapidity, even in the smallest vessels, may be observed to follow each cardiac beat. (9) In a vessel larger than an ultimate capillary, so large as to permit the passage of several colored corpuscles abreast, these may be seen travelling with great apparent velocity in the centre of the stream, whilst the colorless corpuscles move more slowly and with a rolling motion next the walls of the tube, in a layer of plasma called Poiseuille's space. The colored corpuscles also remain separate from each other, and do not exhibit any tendency to adhere together or stick to the walls of the vessels, whereas the colorless corpuscles do both, more especially after the membrane has been exposed for some time to the air, so as to excite the early stages of inflammation. Prof. D. J. Hamilton has shown that the nearer a suspended body approaches the specific gravity of the liquid in which it is immersed the more it tends to keep in the centre of the stream, and he states that the reason why the colored corpuscles keep the centre and the colorless the sides of the stream is that the specific gravity of the former is the same or slightly greater than the blood plasm, whilst that of the colorless corpuscles is less. (10) If the calibre of an ultimate capillary be marked at the beginning of an observation, and again some time afterwards, it will frequently be noticed that it has become narrower or wider, indicating that contractility is one of the properties of capillaries. (11) The velocity is greater in the pulmonary than in the systemic capillaries. (12) The phenomenon known as *diapedesis*, or migration of the white blood corpuscles, first described by Waller in 1846, is readily seen in the mesentery of the frog after inflammation has been excited by exposure to the air for one or two hours (see Fig. 20). It consists of the adhesion to the wall of the vessel of the colorless corpuscles and their protrusion through the wall into the surrounding tissues. Hering is of opinion that it is due partly to the filtration of the colloidal matter of the cell under blood-pressure. Diapedesis is of importance as constituting a part of the inflammatory process. The colorless cells become pus corpuscles (Cohnheim); see PATHOLOGY, vol. xviii. p. 370. (13) If a vascular membrane be gently irritated whilst under the microscope, the capillaries become first slightly narrowed and then dilated, crowded with corpuscles, whilst the blood-stream becomes slower. By-and-by the stream oscillates and then altogether stops. This constitutes *stastis*, a part of the inflammatory process, and is followed by exudation of the plasma of the blood, along with colorless corpuscles, and more rarely colored corpuscles.

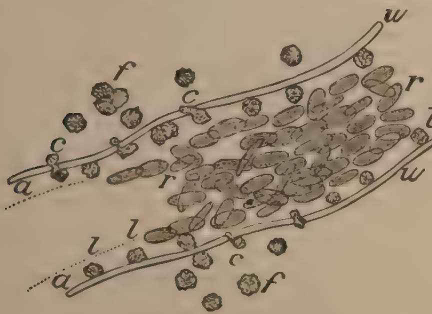

FIG. 20.—Small vessels of mesentery of frog, showing diapedesis of colorless corpuscles. *w*, *w*, vascular walls; *aa*, Poiseuille's space; *r*, *r*, red corpuscles; *l*, *l*, colorless corpuscles adhering to wall; *c*, *c*, colorless corpuscles in various stages of extrusion; *f*, *f*, extruded corpuscles. (Landois and Stirling.)

Vital properties of capillaries.

The most important vital property of capillaries is, as already mentioned, contractility, by which their calibre may be modified. The protoplasm forming their walls contracts when stimulated. Some investigators have supposed the nuclei to be active agents in contraction; but more probably the cell substance is the seat of change. Oxygen causes the nuclei to swell, whilst carbonic acid has the opposite effect. Roy and Graham Brown attach much importance to the active contractility of the capillaries as regulating the distribution of blood, now contracting, now relaxing, according to the needs of the tissues in their vicinity. Elasticity is also a characteristic of the capillary walls.

Arrangement of capillaries.

The arrangement of the capillaries in an organ or tissue is adapted to its functional activity. Where there is great functional activity there is a rich plexus of capillaries, and in the converse case the converse is also true. Contrast, for example, the capillary supply in cartilage with that of muscle, or that of the gray matter of the nerve centres with that of the white matter (see PHYSIOLOGY, vol. xix. p. 49 *sq.*). But, in addition, the distribution of capillaries always corresponds to the intimate structural arrangements of the tissue or organ. So precisely is this the case that a good histologist is able to identify the organ from an injected preparation showing the vessels, although none of the ultimate histological elements of the organ or tissue are to be seen. In muscle, for example, the capillaries exist in the form of elongated meshes; in connective tissue, such as is found beneath the skin, in an irregular network; in the papillæ of the skin, in loops; and to form the glomeruli of the kidney, in close reticulations (see NUTRITION, vol. xvii. p. 704, Fig. 5).

Attractive influence of tissues.

The movement in the capillaries is due to the force of the heart, as modified by the vessels (*vis a tergo*). Some have supposed that it is supplemented by an attractive influence exerted by the tissues (*vis a fronte*); and the statement is supported by the observation that, when there is an increased demand for blood owing to active nutritional changes, there is an increase in the amount of blood flowing to the part, such as occurs, for example, in the mammary gland during lactation, and in the growth of the stag's horn. Such an attractive influence on the part of the tissues is quite conceivable as a force assisting in the inward flow of blood, acting along with capillarity; but its amount is infinitesimally small in comparison with the force exerted by the heart. The force of the heart is sufficient to drive the blood through the capillaries into the veins.

Capillary pulse.

When capillaries are examined in a transparent membrane of a living animal no pulse-like movement is visible. Owing to the elasticity of the vessels the pulse-wave has been almost, if not quite, extinguished, and what might have remained of it is destroyed by the great resistance offered by the numerous capillaries. If these and the arterioles be widely dilated, a pulse may appear in the veins, as occurs when the vaso-dilator fibres of the chorda tympani nerve are stimulated, causing a pulse-like movement in the veins of the submaxillary gland (see PHYSIOLOGY, vol. xix. p. 19). By increasing the extra-vascular pressure pulsations may occur in the capillaries (Roy and Graham Brown). The well-known throbbing in the finger when constricted by an india-rubber band and the throbbing of inflammatory swellings are examples of pulsation in capillaries.

Venous circulation.

Venous Circulation.—The walls of the veins are thinner, less elastic, and more distensible than the walls of the arteries. They contain both elastic and contractile tissue, though to a smaller extent than the arteries. Numerous anastomoses exist between veins and even between superficial and deep veins, so that if the flow of blood be obstructed in one direction it readily finds a passage in another. The circulation in the veins depends (1) on inequality of blood-pressure, the pressure being much less in the veins than in the arteries; (2) on muscular action compressing the veins, and thus, in consequence of the valves found in many veins opening towards the heart, forcing on the blood in the direction of that organ; (3) on the movements of respiration,—inspiration, as already seen, favoring the flow of blood in the great veins towards the heart; and (4) on the suction-like action of the right auricle, and in the case of the lungs that of the left auricle, drawing the blood towards the heart. During venesection, muscular action increases the flow of blood from the divided vein; hence the use of the barber's pole, which was grasped by the patient during bleeding by the barber-surgeon of old. The flow of blood in veins is continuous, or nearly so; when, therefore, a vein is cut, it does not "spurt" as an artery does, but it "wells out" in a stream.

Occasional pulse in veins.

There is normally no pulse in veins; but sometimes a pulse may be observed in the veins of the neck, isochronous with the auricular systole, when there is an obstruction to the passage of blood from the right auricle into the right ventricle. Pulse-tracings (Fig. 21) taken in these circumstances are very similar to those of the cardiac impulse. In this tracing the part *ab* represents the right auricular contraction.

During the systole of the right ventricle the tricuspid valve closes, and, if it be insufficient,—that is, if it does not close properly,—a positive wave is transmitted along the superior vena cava to the jugular (*bc* in the pulse-tracing). The closure of the pulmonary is indicated at *e*. During the diastole of the right auricle and ventricle the blood flows to the heart and the curve descends, *f*. It has also been pointed out by Friedreich that a pulse in the jugular vein does not necessarily mean insufficiency of the tricuspid valve but a weakened condition of the valve in the jugular vein itself, as the pulse will not be propagated into the jugular, even in cases of insufficiency of the tricuspid valve, if the jugular valve be perfect. If there is great obstruction at the mitral orifice, a venous pulse may also be observed, which is associated with engorgement of the right auricle. Sometimes a pulse in the veins occurs when there is such rigidity from atheroma in the walls of the great vessels as to destroy the elastic influence of these parts, and at the same time such a degree of dilatation of the arterioles and capillaries as to admit of the onward propulsion of the movement caused by the heart's contraction. Lastly, a pulse may occur when the blood-pressure rises and falls suddenly as in insufficiency of the aortic valves, and when the arterioles are much dilated. Towards the close of life, when the heart is feeble and effusion may be taking place into the pericardium, a venous pulse may be observed.

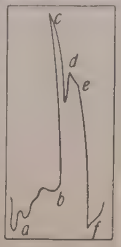

FIG. 21.—Tracing of venous pulse from insufficiency of the tricuspid valve (Friedreich).

Venous sounds.

If a stethoscope be placed at the root of the neck above the collar bones, and on the right side in particular, a whistling, rushing, or blowing sound will be heard. This is the *bruit de diable*, familiar to physicians. If heard without pressure being made by the stethoscope it is abnormal, as it occurs in conditions of anæmia from almost any cause; but it may be heard in a healthy person when pressure is applied and when the head is turned to the opposite side. It is held to be due to the vibration of the blood in rushing from the contracted portion of the common jugular vein into the more dilated part of this vessel. During the auricular diastole and during inspiration it is more marked, as the blood then flows more rapidly in the veins towards the heart.

Phenomena of General Circulation.

Prime factors influencing circulation.

Having described the structure and functions of the organs concerned in the circulation,—namely, heart, arteries, capillaries, and veins,—we are in a position to consider the phenomena of the circulation as a whole. Consider the organs of the circulation as a closed system of tubes, over-filled with blood; when the tubes are in a state of rest, it is evident that, if the blood be uniformly diffused and under the same pressure, it will remain motionless and in equilibrium. When the pressure is changed at any point, as occurs when the left ventricle contracts and throws blood into the arterial system, the blood will move from the part where the pressure is higher to where it is lower; in other words, there will be circulation as a consequence of the difference of pressure. When the heart stops beating, the blood continues to flow more and more slowly until the difference of pressure is equalized, and then there is no circulation. Each stroke of the heart throws as much blood into the arteries as flows into the heart from the veins; the orifices of the veins at the heart are more distensible than the beginnings of the arteries, and consequently the arterial pressure rises more rapidly than the venous pressure diminishes, and thus the beating of the heart raises the mean pressure throughout the arterial system. The circulation is therefore influenced by two factors,—(1) the heart as regards number, strength, and volume of beats; and (2) the amount of resistance in the arterioles. Modifications of these influences are the pressure and the velocity of the blood.

Blood-pressure in vessels.

As the blood is circulating through the vessels under the influence of the action of the heart, it exerts a certain pressure or tension, the existence of which is shown by the jet of blood which spurts out on the puncture of an artery, and the amount of which is indicated by the height to which the jet is propelled. An instrument for measuring this pressure, termed a kymograph, has been devised by Ludwig. But this apparatus, owing to the inertia of the mass of mercury,—the medium used,—can only register mean blood-pressure, and the more delicate variations escape notice. Fick in 1864 attempted to register these smaller fluctuations by means of a curved spring-kymograph, consisting of a hollow spring, which is made to oscillate by variations of pressure communicated to the interior. Small portions of a tracing taken with the mercurial manometric kymograph of Ludwig are shown in Fig. 22. From this it will be observed that there is (1) an increase and diminution of blood-pressure with each cardiac beat, as is shown in the smaller curves, and (2) an increase and diminution produced by respiratory movements, the increase occurring chiefly during inspiration and the decrease chiefly during expiration, as is indicated by the larger waves. It is evident also that all the smaller curves have the same general character, and that they reveal nothing as to variation in pressure during individual beats. To show such variations, Fick's kymograph must be used, when a tracing will be obtained in which slight oscillations of pressure in the down-stroke of each separate beat may be observed. By employing the different forms of kymograph the following conclusions have been arrived at.

Arterial pressure.

(*a*) *Arterial Pressure.*—(1) The pressure diminishes from the heart to the capillaries. (2) It attains its maximum in the ventricle at the moment of systole, and its minimum in the auricle at the moment of diastole, at which time also the pressure in the auricles and in the great veins may be negative, that is, below atmospheric pressure. (3) The mean blood-pressure in the large arteries of large mammals and of man is equal to that of a mercurial column 5.5 to 6.3 inches in height. (4) The blood-pressure in various animals has been ascertained to be as follows, the results being expressed in terms of a column of mercury of the indicated number of inches in height. Carotid of horse, 6.34; carotid of dog, 5.89 (Poiseuille.) Carotid of horse, 4.8 to 8.42; carotid of dog, 5.89; carotid of goat, 4.64 to 5.31; carotid of rabbit, 3.54; carotid of fowl, 3.46 to 6.73; aorta of frog, .86 to 1.14; gill artery of pike, 1.38 to 3.3 (Volkmann). Carotid of dog, 5.12 to 7.48 (Ludwig). Carotid of calf, 6.97; carotid of sheep, 6.65; carotid of goose, 6.38; carotid of stork, 6.34; brachial artery of pigeon, 6.57; carotid of cat, 5.9: brachial artery of man during operation, 4.33 to 4.72 (Faivre). Anterior tibial artery of boy, 3.93 to 6.3 (E. Albert). It no doubt varies even in animals of the same species. (5) The arterial pressure at any given point undergoes periodic variations, increasing at the instant of ventricular systole and diminishing during diastole; they are most marked in the arteries near the heart. (6) These periodic variations may be observed in the intermittent spurting of an artery when it is punctured. (7) It is necessary to distinguish between the mean arterial pressure at any points of an artery and the mean pressure of the blood in the whole arterial system, which can only be obtained by taking the mean of the pressures in many different arteries at various distances from the heart. (8) The mean arterial pressure depends directly on the quantity of blood in the arterial system, and consequently on the total calibre of the system, so that any diminution of calibre, produced mechanically or by nervous influences, will increase the mean arterial pressure. (9) The mean arterial pressure increases with the energy of the beats of the heart. (10) The blood-pressure becomes greater with increased and accelerated action of the heart, sometimes with plethora, and after an increase in the amount of blood, such as occurs after a full meal or after transfusion of blood, whilst it becomes smaller during diminished or enfeebled action of the heart, in anæmia, and after hæmorrhage or excretions from the blood by the skin, kidneys, or bowels (Landois). (11) The pressure is affected by the degree of contraction or of dilatation of the bloodvessels, according as they are influenced by the nervous system. (12) The pressure is increased in cases of sclerosis or hardening of the arterial walls, in lead poisoning after injection of ergotin (which contracts the small arterioles) or of digitalis (which acts on the heart), where there is granular or contracted kidney, and in cardiac hypertrophy with dilatation. And (13) the pressure is diminished in fever, in chlorotic anæmia, in phthisis, and by severe hæmorrhage.

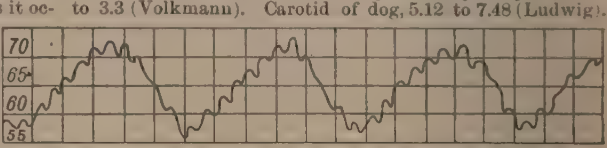

FIG. 22.—Mercurial kymographic tracing from carotid of dog, showing form of curve on a large scale. The figures on the left represent mm. of mercury. (Marey.)

(*b*) *Venous Pressure.*—(1) In the veins near the heart the

Venous pressure.

pressure is only one-twentieth to one-tenth of that of the corresponding arteries. (2) During auricular diastole the pressure in the veins near the heart may become negative (= — .0039 inch of mercury). (3) There are no periodic variations of pressure in the veins as in the arteries, except in the great venous trunks in the neck and near the heart, where there is a diminution of pressure during auricular diastole and an increase during auricular systole. (4) Great activity of the heart diminishes venous, while it increases arterial pressure. (5) The pressure increases in the veins according to their distance from the heart; thus, in the external facial vein of the sheep it is equal to a column of mercury .12 inch in height; in the trachial to a column .16 inch high; in branches of the trachial, .35 inch; in the crural vein, .45 (H. Jacobson). (6) Plethora increases venous pressure, whilst anæmia diminishes it. (7) Inspiration causes in the great veins near the heart an increase in pressure, whilst expiration diminishes it; but the respiratory movements "do not affect the venous stream in peripheral veins" (Stirling). (7) Changes in the position of the limbs affect venous pressure hydrostatically: thus, elevation of the extremities favors the flow of blood towards the heart; but, if the heart hangs downwards, the face becomes turgid, as the outflow by the veins is retarded. (8) Gravity favors the emptying of descending and hinders the emptying of ascending veins, so that the pressure becomes less in the former and greater in the latter. (9) As already stated, muscular movement by compressing the veins, aided by the mechanism of the valves, favors the flow of blood towards the heart, and thus increases the pressure in these vessels.

Capillary pressure.

(*c*) *Capillary Pressure.*—For obvious reasons capillary pressure has not been directly measured. Von Kries has measured the amount of pressure necessary to occlude the capillaries in an area abounding in these vessels, such as the skin at the root of the nail on the terminal phalanx or on the ear in man, and on the mucous membrane of the gum in rabbits. He found the pressure in the capillaries of the hand, when the hand is raised, to be equal to .95 inch of mercury, when it hangs down, 2.13, in the ear .79, and in the gum 1.26. Roy and Graham Brown also measured the pressure necessary to close the capillaries in the web of the frog's foot, in the tongue and mesentery of the frog, and in the tail of newts and small fishes. It is evident that any condition favoring the afflux of blood to a capillary area will increase the pressure in the capillaries, such as the dilatation of the small arterioles conveying blood to an area of capillaries, contraction of the venules carrying off the blood from it, or any increase of pressure in the arterioles or in the venules. The arrangement and position of the capillary network must affect the pressure; the pressure in the capillaries of the glomeruli of the kidney must, for instance, be greater than in those of the skin, as in the former position there is increased resistance owing to the double set of capillaries (see NUTRITION, vol. xxvii. p. 697). Finally, any change in the degree of contraction of the wall of the capillary itself will affect the pressure.

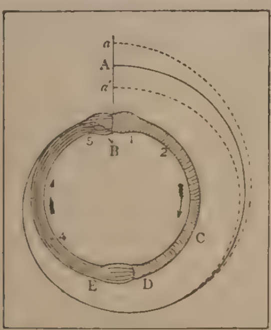

FIG. 23.—Diagram showing pressure in vascular system. 1, Ventricle; 2, arteries; E, D, capillaries; 4, veins; 5, auricle; A to C, line of pressure in great arteries; C to D, in small arteries; D to E, in capillaries; E to B in veins. The dotted lines indicate pressure during ventricular systole (*a*C) and diastole (*a'*C). Beyond C the blood-pressure is uniform as far as the auricle B, where it is negative during auricular diastole. (Beaunis.)

The general facts regarding pressure in arteries, capillaries, and veins are illustrated by Fig. 23.

Velocity of blood.

Various attempts have been made by Volkmann, Vierordt, Ludwig and Dogiel, Hering, and Chauveau and Lortet to measure the velocity of the circulation, and special instruments have been invented for that purpose. In 1850 Volkmann constructed the hæmadromometer; this was followed by the hæmatachometer of Vierordt in 1858 and by the hæmadromograph of Chauveau and Lortet in 1867. These instruments are not now much used, having been superseded by the *stromuhr* (current-clock) or rheometer of Ludwig and Dogiel, which was invented in 1867. This instrument measures the amount of blood which passes through an artery in a given time. It consists of two glass bulbs of equal capacity communicating by a tube. One of the bulbs is filled with oil, which is expelled by the blood into the second (empty) bulb. The instrument is then reversed on its socket so that the bulb containing the blood is farthest from the heart, and the former process is repeated. From the time occupied in filling and refilling the velocity of the blood in the artery of supply can be calculated.

Results of experiment as to velocity.

The following figures give, in inches per second, the velocities of the blood in different vessels. Carotid of dog, 8.07 to 14.06; carotid of horse, 12.05; maxillary of horse, 9.13; metatarsal of horse, 2.2 (Volkmann). Mean velocity in carotid of dog, 10.28; in carotid of dog at end of diastole, 8.46; at end of systole, 11.69; in crural artery of dog at end of diastole, 5.51; at end of systole, 9.41 (Vierordt). During systole in carotid of horse, 9.84; at time of dicrotic wave, 8.66; at end of diastole, 5.9 (Chauveau, Bertolus, Laroyenne). In carotid of rabbits, from 3.7 to 8.9; in carotid of dog, weighing 51.2 ℔, poisoned with morphia, from 13.74 to 28.86; in carotid of another dog, weighing 26.69 ℔, from 9.57 to 20.47; in carotid of dog, weighing 7.85 ℔, in which the sympathetic nerve had been cut, from 8.03 to 13.35; and in carotid of another dog, weighing 6.97 ℔, poisoned with morphia, from 13.35 to 18.03 (Dogiel). The velocity in the capillaries cannot be directly measured. E. H. Weber gives it at .032 inch per second in capillaries of mammals and .021 in those of the frog. Vierordt gives the velocity in man as .024 to .035 inch per second. Volkmann states that the flow of blood in mammalian capillaries is five hundred times slower than in the aorta. Donders asserts that the velocity of the current in the smaller arterioles is ten times faster than in the capillaries. When the current reaches the veins it is accelerated in consequence of diminished resistance, but even in the larger venous trunks it is .5 to .75 times less than in the corresponding arteries. The following general conclusions may be drawn: (1) The velocity of the blood is in inverse ratio to the total calibre of the vessels: rapid in the aorta, it diminishes as we recede from it. (2) Each systole is followed by an increase in the velocity of the blood in the larger vessels. (3) In the smaller arteries, capillaries and smaller veins the velocity is uniform and constant. (4) The velocity increases in the venous system as we approach the heart. (5) In the large arteries the movements of inspiration retard the velocity, whilst those of expiration increase it. (6) In the large veins the movement of respiration, and also the suction action of the auricle during diastole, cause a rhythmic increase and diminution of the velocity. The explanation of these variations in velocity is obvious. As the arteries pass outwards they give off branches, the united calibre of which is, with rare exceptions, greater than that of the parent vessel. Thus, as Küss expresses it, the arterial system may be regarded as a cone, the base of which ends in the capillaries, whilst the summit is at the aorta; and the venous system is a second cone, the base being also at the capillaries and the apex at the right auricle. Vierordt states that the sectional area of the capillaries is to that of the aorta as 800 to 1; but, as the sectional area of the venous orifices at the heart is greater than that of the arterial orifices, the ratio of the sectional area of the capillaries to that of the veins at the heart has been stated as 400 to 1. The increased sectional area retards the velocity, and the velocity of the blood-current in sections of the vessels at various points is inversely as their calibre. The velocity of the blood does not depend on the mean blood-pressure, and, as was pointed out by Ludwig and Dogiel, the velocity in any section of a vessel depends on (1) the *vis a tergo* (*i.e.*, action of the heart) and (2) the amount of resistance at the periphery.

Duration of circulation.

It is important to distinguish between the rapidity of the blood-current and the time occupied by a blood corpuscle in making a complete circuit through the heart and vessels, say, from the left ventricle to the left ventricle again. Attempts have been made to measure the time, starting from the jugular vein. Hering injected into that vein a few drops of a 2 per cent. solution of ferro-cyanide of potassium, and then examined the blood of the opposite jugular every five seconds by testing with perchloride of iron,—the formation of Prussian blue indicating the moment when the ferro-cyanide made its appearance in the blood of the jugular after having made a tour of the circulation. Vierordt modified the method by examining the blood received from the jugular each half-second. The duration of the circulation as thus determined for various animals is as follows,—horse, 31.5 seconds; dog, 16.7; rabbit, 7.79; hedgehog, 7.61; cat, 6.69; goose, 10.86; duck, 10.64; buzzard, 6.73; and common fowl, 5.17 seconds. Vierordt also made the discovery that in most animals the duration of the circulation is equal to the time in which the heart makes about twenty-seven beats. These facts are illustrated in the following table:

Animal.	Weight of Body.	Pulse Beats Per Minute.	Number of Pulsations in the Circulation.
Guinea-pig.........	7.83 oz.	320	23.7
Cat....................	46.28 "	240	26.8
Hedgehog...........	32.13 "	189	23.8
Rabbit................	50.59 "	220	28.5
Dog....................	20.28 lb	96	26.7
Horse..................	83.78 "	55	28.8
Fowl....................	46.98 oz.	354	30.5
Buzzard..............	24.44 "	282	31.6
Duck..................	46.7 "	163	28.9
Goose..................	99.54 "	144	26.0

It may also be shown by another method that a volume of blood equal to that in the whole body passes through the heart in about thirty pulsations. Taking the quantity of blood in the body as one-twelfth of the total weight, a man weighing 140 lb contains 11⅔ lb, or 5292 grammes, of blood, which represent in capacity 5302 cubic centimetres. Each beat of the heart throws 172 cubic centimetres into the aorta; therefore the equivalent of the total quantity of blood in the body passes through the heart in about 30 pulsations. Taking the pulse beat at 72 per minute, it follows that the duration of the circulation is about 26 seconds.

Volume of organs.

It has been satisfactorily proved by Mosso, Von Basch, Dogiel, and François Franck that there is a slight change in the volume of any distensible organ with each beat of the heart. Mosso devised the plethysmograph,[1] an instrument by which the following results have been obtained. (1) The volume of an organ is not fixed, but varies according to the amount of blood contained in it. (2) Its volume changes with each cardiac pulsation, increasing when blood is forced into it and diminishing by the emptying of the capillaries into the veins. (3) Variations in the volume of one or more organs, say, by compression, or by the application of cold, or by the internal administration of substances which affect the calibre of bloodvessels, such as ergot, cause corresponding variations in the volume of other organs. (4) The pulsatile variations are very similar to the pulse-curve, and there are respiratory undulations corresponding to similar variations in blood-pressure tracings. (5) Movements of the limb cause diminution in volume, as was shown by Glisson in 1677, in consequence of acceleration of the venous current. (6) Mental exercise and sleep cause a diminution in the volume of the limb (Mosso). (7) So delicately attuned is the organism that music has been observed to cause a rise and fall in the tracings (Dogiel).

Distribution of blood.

The blood is distributed throughout the body in varying proportions, according to the requirement of any set of organs at a particular time. When any tissue or organ is active, there is a determination of blood towards it, the amount being increased from 30 to 50 per cent.: thus, during digestion the mucous membrane of the stomach and intestinal organs is richly supplied with blood. Increased muscular velocity is always accompanied by increased vascularity; but, whilst this is the rule, there are organs, such as the heart, the muscles of respiration, and nervous centres like those in the medulla oblongata, in which there is a condition of continuous activity, and in which there is a uniform vascularity. Seeing that the activity of certain organs varies at different times, it follows that, whilst some organs are congested, others are at rest. In the child there appears to be a different distribution of blood from what obtains in the adult. The heart of a child is relatively small up to puberty, while the vessels are relatively large; after puberty the reverse is the case. Arterial pressure is less in the child than in the adult, whilst the pressure in the pulmonary circulation is larger in the child than in the adult (Beneke). Attempts have been made to estimate the distribution of blood after death. Ranke states that one-fourth of the total blood is in the muscles, one-fourth in the liver, one-fourth in the heart and vessels, and the remaining fourth in the rest of the organs.

Speical Forms of Circulation.

Cranial.

The cranial circulation has been already described under PHYSIOLOGY, vol. xix. p. 49.

Hepatic.

The peculiarity of the portal circulation is that the blood passes through two sets of capillaries. Arterial blood is conveyed to the stomach, spleen, pancreas, and intestines by branches of the abdominal aorta. These branches divide and subdivide, terminating in a capillary plexus in the various organs above enumerated. From this plexus the radicals of the various veins spring, and they unite with each other into larger and larger trunks until by the confluence of the mesenteric veins with the splenic vein the portal vein is formed. The portal vein conveys the blood to the liver, where it divides into smaller and smaller branches constituting a plexus in the lobules of the liver. From this plexus spring the roots of the hepatic vein, which conveys the blood from the liver to the inferior vena cava (see NUTRITION, vol. xvii. p. 699). There are thus in the portal circulation two sets of capillaries,—one in the abdominal viscera and the other in the liver. Ligature of the portal vein causes distension of all the abdominal vessels and a highly congested state of the abdominal viscera, whilst the blood-pressure quickly falls, and the animal dies. So distensible are the abdominal vessels that they can contain nearly all the blood in the body. Blood from such congested vessels has toxic properties (Schiff and Lautenbach). The ventricular systole may send a pulse down the valveless inferior vena cava and cause a pulse in the liver. The liver swells with each systole and relaxes with each diastole of the heart.

Pulmonary.

The pulmonary artery, carrying venous blood, divides and subdivides, and the smallest branches end in a plexus of capillaries on the walls of the air-cells of the lung. From this plexus the radicles of the pulmonary veins originate; and finally the four portal veins, two from each lung, carry the arterialized blood to the left auricle. Considering the apparently small extent of the pulmonary as compared with the systemic circulation, and the fact that the two ventricles, of about equal capacity, empty themselves simultaneously, it is clear that the pulmonary circulation presents many points of interest. In the first place, the pressure in the pulmonary artery is considerably less than that of the aorta. In 1850 it was determined by Ludwig and Beutner to be in the dog equal to a mercurial column of 1.17 inches, in the cat to one of .69 inch, and in the rabbit .47 inch, or about three times less in the dog, four times less in the rabbit, and five times less in the cat than the pressure in the aorta. Hering passed simultaneously a tube through the muscular walls of each ventricle of a calf and the blood rose in the tube in the right ventricle 21 inches and in the left 33.4 inches (quoted by Landois and Stirling). Fick and Badoud found a pressure of 3.54 in the pulmonary artery of the dog, whilst the carotid pressure at the same time was 4.17 inches. The ratio of pulmonary to aortic pressure has been stated as 1 to 3 (Beutner and Marey) and as 2 to 5 (Goltz and Gaule).

Influence of respiration in pulmonary circulation.

Next, it is important to note the peculiar physical conditions in the chest during respiration. As already shown (p. 111), the lungs are distended in consequence of the positive pressure on their inner surfaces being greater than the negative pressure on their outer pleural surfaces. But when the lungs are distended by a full inspiration they exert an elastic force (termed elastic recoil or "elastic traction") amounting to about 1.18 inches of mercury. Outside the lungs, in the cavity of the chest, the surface of the heart and vessels is subjected to a pressure which is the difference between atmospheric pressure (29.92 inches) and the "elastic traction" (1.18 inches), or 28.74 inches. It is clear that the more the lungs are distended the greater is the elastic traction, and consequently the less the pressure on the outer surface of the vessels. The thin-walled pulmonary veins yield more during a deep inspiration, thus diminishing pressure, than the thicker-walled pulmonary artery, whereby the flow of blood from the capillaries of the lung by the pulmonary veins to the left auricle is favored. On the other hand expiration by increasing the pressure tends to retard the flow of blood. Further, the velocity of the stream of blood is accelerated in the pulmonary vessels by inspiration and retarded by expiration. As regards the influence of the movements of the lung on the calibre of the pulmonary capillaries and smaller vessels, experiment has shown that the bloodvessels of the lungs containing air and distended are wider than those of collapsed lungs. Suppose an elastic bag having minute tubes in its walls to be dilated in a free space, the lumen of these tubes will be diminished; but, if it be placed in a closed space, as in a wide glass bottle, and if the pressure on its outer surface be diminished by removing air from the space between the bag and the side of the bottle, the bag will distend and the lumen of the tubes will be increased. Thus it is evident that inspiration, by increasing the calibre of the pulmonary vessels, draws blood towards the lungs, and the movements of the lungs become an effective force in carrying on the pulmonary circulation. The velocity of the blood is greater in the pulmonary than in the systemic capillaries, and greater in the pulmonary veins than in the pulmonary arteries. The great degree of distensibility of the pulmonary vessels allows of frequent adjustments being made, so that, within limits, as much blood in a given time will pass through the pulmonary as through the systemic circulation. This adjustment, however, may be readily disturbed. For example, violent muscular exertion hurries the blood along the veins to the right side of the heart, and by the right ventricle the blood is discharged into the pulmonary circulation. If more arrives than can be transmitted to the left auricle by the pulmonary veins in a given time, the pulmonary capillaries become engorged, breathing becomes quick and possibly irregular, the right side of the heart becomes engorged, signs of venous congestion appear in the flushed face and turgid veins, and perhaps the pulmonary capillaries may rupture, causing hæmorrhage from the lung. The weaker the muscular structure of the heart the more likely is this to occur. Hence the breathlessness in many cardiac affections, aggravated by muscular exertion, more especially in ascending a stair or hill.

---

Fœtal.

In the mature fœtus the fluid brought from the placenta by the umbilical vein is partly conveyed at once to the vena cava ascendens by means of the *ductus venosus* and partly flows through two trunks that unite with the portal vein, returning the blood from the intestines into the substance of the liver, thence to be carried back to the vena cava by the hepatic vein. Having thus been transmitted through the placenta and the liver, the blood that enters the vena cava is purely arterial in character; but, being mixed in the vessels with the venous blood returned from the trunk and lower extremities, it loses this character in some degree by the time that it reaches the heart. In the right auricle, which it then enters, it would also be mixed with the venous blood brought down from the head and upper extremities by the descending vena cava were it not that a provision exists to impede (if it does not entirely prevent) any further admixture. This consists in the arrangement of the Eustachian valve, which directs the arterial current (that flows upwards through the ascending vena cava) into the left side of the heart, through the foramen ovale,—an opening in the septum between the auricles,—whilst it directs the venous current (that is being returned by the superior vena cava) into the right ventricle. When the ventricles contract, the arterial blood contained in the left is propelled into the ascending aorta, and supplies the branches that proceed to the head and upper extremities before it undergoes any further admixture, whilst the venous blood contained in the right ventricle is forced into the pulmonary artery, and thence through the *ductus arteriosus*—branching off from the pulmonary artery before it passes to the two lungs—into the descending aorta, mingling with the arterial currents which that vessel previously conveyed, and thus supplying the trunk and lower extremities with a mixed fluid. A portion of this is conveyed by the umbilical arteries to the placenta, in which it undergoes the renovating influence of the maternal blood, and from which it is returned in a state of purity. In consequence of this arrangement the head and upper extremities are supplied with pure blood returning from the placenta, whilst the rest of the body receives blood which is partly venous. This is probably the explanation of the fact that the head and upper extremities are most developed, and from their weight occupy the inferior position in the uterus. At birth the course of the circulation undergoes changes. As soon as the lungs are distended by the first inspiration, a portion of the blood of the pulmonary artery is diverted into them and undergoes aeration; and, as this portion increases with the full activity of the lungs, the ductus arteriosus gradually shrinks, and its cavity finally becomes obliterated. At the same time the foramen ovale is closed by a valvular fold, and thus the direct communication between the two auricles is cut off. When these changes have been accomplished, the circulation, which was before carried on upon the plan of that of the higher reptiles, becomes that of the complete warm-blooded animal, all the blood which has been returned in a venous state to the right side of the heart being transmitted through the lungs before it can reach the left side or be propelled from its arterial trunks (Allen Thomson). After birth the umbilical arteries shrink and close up and become the lateral ligaments of the bladder, while their upper parts remain as the superior vesical arteries. The umbilical vein becomes the ligamentum teres. The ductus venosus also shrinks and finally is closed. The foramen ovale is also closed, and the ductus arteriosus shrivels and becomes the ligamentum arteriosum.

The Innervation of Bloodvessels.

Effects upon circulation of stimulating various nerves.

This has already been described under PHYSIOLOGY (vol. xix. p. 34); but there are several points of interest that can only be thoroughly understood after studying the general conditions affecting, and the mode of measuring, the pressure of the blood. Stimulation of the pneumogastric nerve in the neck slows the rate of the heart-beat, and, if the stimulation be strong, arrests the heart in a state of diastole. Suppose a kymograph to be connected with the carotid in the neck of a rabbit deeply under the influence of chloral so as to be quite unconscious of pain; if then one of the vagi in the neck be stimulated, the blood-pressure curve at once falls; and on removing the stimulation it rises to its former height by a few leaps and bounds. Whilst this occurs in the arteries, the venous pressure rises in consequence of the flow of blood into them from the arteries. But the pressure may be influenced by another method. As was pointed out by Ludwig and Owsjannikow, a centre exists in the medulla oblongata (vaso-motor centre) whence influences emanate that tend to keep the vessels in a more or less contracted condition. If this centre be injured, the smaller bloodvessels throughout the body dilate,—in short, they are paralyzed,—and receive more blood, and consequently the pressure in the larger vessels at once falls. This vaso-motor centre in turn can be influenced by impressions reaching it from the periphery. This was clearly proved by Cyon in 1866, when he discovered the function of the depressor nerve, a small nerve (the superior cardiac) originating in the rabbit from the superior laryngeal and from the pneumogastric nerve, but in many animals blended with the pneumogastric nerve. Stimulation of the distal end of this nerve produces no effect; but stimulation of the cephalic end causes a great fall of blood-pressure and a diminution in the frequency of the pulse (see PHYSIOLOGY, vol. xix. p. 34 and Fig. 11). Similar depressor filaments exist in the trunk of the vagus below the origin of the superior cardiac nerve (depressor of Cyon), in the nerves coming from the lungs, in the great articular nerve, in the tibial, and in all probability in all sensory nerves. Further, it may be influenced by nerve fibres the stimulation of which excites the centre, causing a rise in pressure (pressor nerves). Such filaments have been experimentally demonstrated to exist in the superior and inferior laryngeal nerves, in the trigeminus, and in the cervical sympathetic. The vaso-motor centre is therefore under the influence of two antagonistic sets of impulses,—one stimulating it, causing constriction of the smaller vessels and a rise of arterial pressure, the other inhibiting it, causing dilatation of the smaller vessels together with a fall of pressure.

Connection of respiratory undulations with vaso-motor centre.

But this is not all. On examining a blood-pressure tracing it is seen that the arterial pressure is influenced by the movements of respiration, the larger waves corresponding to these movements. To ascertain precisely how much of the wave corresponds to inspiration and how much to expiration, suppose a blood-pressure taken from the carotid artery, whilst at the same time arrangements are made for recording simultaneously the variations of intra-thoracic pressure. It is then easily seen that, when expiration begins and the expiratory pressure rises the blood-pressure rises, while when inspiration begins both fall. Inspiration removes pressure from the outer surface of the vessels and thus allows the walls both of the great veins and of the aorta to distend; but the thin-walled veins yield to a greater extent than the thick-walled aorta. Consequently during inspiration the blood tends to accumulate in the great veins and in the right side of the heart and less escapes by the aorta, and the blood-pressure in the aorta falls. On the other hand, during expiration the blood-pressure rises, owing to the opposite set of conditions. Roughly speaking therefore, during inspiration blood-pressure falls, whilst during expiration it rises. But a careful examination of the curves shows that they do not exactly coincide as to their maxima and minima. Thus the blood-pressure rises before the rise of expiratory pressure; or, in other words, during the first part of inspiration there is a fall of pressure and during the second part a rise. This cannot be explained by the mechanical movements of the chest wall, but is caused, partially at all events, by the action of the vaso-motor centre. During the latter portion of the inspiratory period impulses pass from this centre, causing constriction of the smaller vessels, and consequently the rise of arterial pressure observed during this time. Again, an examination of a blood-pressure tracing shows that during the fall of the respiratory curve the smaller curves are larger and fewer in number than during the rise of the curve. After section of the vagi this difference disappears, and it can only therefore be explained by stating that during the first portion of the time of inspiration, and during the fall of arterial pressure, the cardio-inhibitory centre also acts, slowing the beat of the heart. Another important fact showing that the respiratory undulations cannot be accounted for by the mechanical movements of the chest wall is that they appear in a blood-pressure tracing taken during artificial respiration. When a canula is inserted into the trachea and air is forced into the chest by a bellows, it is evident that the mechanical conditions are not those of ordinary respiration. When air is forced in, inflating the lungs to correspond to inspiration, the intra-thoracic pressure is increased instead of diminished, as in ordinary respiration, and when the air is sucked out to correspond to expiration the intra-thoracic pressure is diminished instead of being increased as in ordinary expiration; and still the respiratory curves remain. If artificial respiration be suddenly stopped, the blood-pressure quickly rises; but this does not occur to nearly the same extent if the spinal cord be divided. In other words, the rise of blood-pressure when artificial respiration is arrested is due to stimulation of the vaso-motor centre in the medulla by the circulation through it of blood too highly venous owing to stoppage of the circulation, as is proved by the fact, that, if the influence of the vasa-motor centre be removed, the rise of blood-pressure does not take place. Finally, if during artificial respiration both vagi be cut so as to remove the influence of the cardio-inhibitory centre, and respiration be stopped, the pressure will rise as already described, and in a short time a series of undulations will appear in the blood-pressure tracing known as the Traube-Hering curves,—a rising and falling of blood-pressure not due to the action of the heart, as they continue even when a pump is substituted for that organ, nor to the movements of respiration, but to a "waxing and waning" of the activity of the vaso-motor centre itself, contracting and dilating the bloodvessels and thus influencing the peripheral resistance. To sum up, the circulation is affected by the nervous system—(1) by the inhibitory action of the vagi in restraining the activity of the heart; (2) by the accelerating action of fibres in the sympathetic, stimulating the activity of the heart; (3) by the action of the intrinsic cardiac ganglia affecting the heart directly; (4) by the action of the vaso-motor centre (vaso constrictor nerves) in the medulla, tending to keep up a greater or less degree of constriction of the vessels; (5) by the action of vaso-dilator nerves inhibiting the vessels, allowing them to dilate in a manner similar to the cardio-inhibitory action of fibres in the vagi; (6) by the influence on the vaso-motor centre of impulses coming from the periphery,—pressor fibres stimulating it, depressor fibres inhibiting it; (7) by the diffusion of impulses in the medulla from the respiratory centres; (8) by the interaction of the vaso-motor, respiratory, and cardio-inhibitory centres in the medulla; and (9) by rhythmic changes in the vaso-motor centre itself. See PHYSIOLOGY, vol. xix. p. 33 *sq.*

Bibliography.—A copious list of works relating to the anatomy of the organs of the circulation will be found in Quain's *Anatomy*, edited by Allen Thomson, E. A. Schäfer, and George D. Thane, 9th ed., vol. ii. p. 916; and on the physiology of the circulation in Beaunis's *Physiologie Humaine*, 2d ed., 1885, and in Landois and Stirling's *Text-Book of Human Physiology*, 2d ed., vol. i. p. 557. To this last able work, to A. Rollett's elaborate essay, "Physiologie der Blutbewegung," in Herman's *Handbuch der Physiologie*, and to Prof. Michael Foster's *Text-Book of Physiology*, 4th ed., the author is specially indebted in the preparation of this article. As to the action of drugs and poisons on the circulation, reference is made to Lauder Brunton's *Text-Book of Pharmacology*, etc., 2d. ed., 1886. For a brief account of the historical development of our knowledge of the circulation, see abstracts of lectures by the present writer, delivered before the Royal Institution, in *British Medical Journal* for 1883. (J. G. M.)

VASILKOFF, a district town of Russia, in the government of Kieff, is situated 22 miles by rail to the southwest of that city. Its 16,600 inhabitants support themselves chiefly by agriculture and the transport of merchandise; there is also some manufacture of tobacco and soap.

Vasilkoff was founded in the 10th century, but laid waste during the Mongolian invasion. In 1320 it was taken by the Lithuanians, and later on by the Poles, under whom it remained until 1686, when it was annexed to Russia.

VASTO, a fortified town of Italy, in the province of Chieti, stands high on an olive-clad slope, about a mile from the Adriatic and 131 miles southeast from Ancona. It is still surrounded by its mediæval walls, and commands fine views extending to the Tremiti Islands and Monte Gargano. The cathedral, with a Gothic façade, has no special interest; the municipal buildings contain a collection of Roman antiquities and inscriptions. There are manufactures of earthenware, woollen cloth and silk; but the inhabitants are chiefly employed in the culture of the olive and in fishing. The population in 1881 was 9761 (commune 13,883).

Vasto, the *Histonium* of the ancient geographers, was a flourishing municipal town under the Roman empire, as is shown by the numerous remains of theatres, baths and other public edifices. It was, and still is, subject to severe earth tremors.

VATICAN COUNCIL. The Vatican Council is the first and only plenary council of the Latin Church held since the close of the Council of Trent in 1563. But it bears very slight resemblance to that assembly in the circumstances of its origin, objects, and proceedings. The Council of Trent was all but forced upon the Papacy by the demands of the principal Catholic states of Europe, and by the religious and political necessities of the time. It was convened for the purposes of endeavoring to secure the return of the Lutherans, Calvinists, and other revolted bodies to the Roman Church, and of applying stringent measures of reform to amend the numerous practical abuses and scandals which had mainly caused the revolt. And, while it failed conspicuously in the former of these objects, it did achieve a certain degree of success in the latter, by a variety of disciplinary enactments covering a large range of subjects, and was followed, in point of fact, by a marked improvement in clerical morals and diligence. The Vatican Council, contrariwise, originated with the Papacy alone, and was neither demanded nor desired by Roman Catholic Christendom. Its object was confined to securing the triumph of the hyper-Ultramontane school within the Roman obedience by establishing papal autocracy as divine and infallible; and it made no attempt whatever beyond a sterile discussion, not published in its Acts, to deal with any of the abuses and scandals which had either survived the Tridentine reforms or had sprung up since. While the Council of Trent did much to repair the damage done to the personal authority of the popes by the incidents of the "great schism" and the character of the pontiffs who sat during the close of the 15th and the beginning of the 16th century, it left several questions concerning the source and extent of papal authority undecided, which proved a fruitful cause of debate between the Gallican and Ultramontane schools of theology, the former minimizing the papal claims as far as is compatible with acceptance of the tenet of the Petrine privilege, and viewing the Papacy as a constitutional monarchy under strict limitations, the latter holding it to be an autocracy resting on a divine charter, and incapable of restraint on the part of its subjects. But the French Revolution, by breaking up the old Gallican Church, led to the substitution of a largely Ultramontane episcopate in France under the concordat between Pius VII. and Napoleon I., and thereby to the permanent declension of the moderate school, while, on the other hand, a variety of causes brought the Jesuits, recalled into corporate existence by the same Pius VII. in 1814, after forty years' suppression, again into the same position of chief influence in the Latin Church which they had occupied in the heyday of the counter-

Reformation. They have always held steadily to the military ideas of their founder, and have therefore unceasingly striven to centralize and concentrate ecclesiastical authority, to remove constitutional limitations upon its exercise, and to make it prompt, unfaltering, and trenchant in action. Clearly, if the Papacy could be converted into an absolute monarchy, this end would be attained at a single stroke, because the mere fiat of the supreme pontiff would thenceforward suffice as warrant for all ecclesiastical action, thus dispensing with cumbrous and dilatory machinery of every kind; and his delegated authority would enable any person wielding it to act with similar efficacy and despatch.

With the accession of Pius IX. to the papal chair in 1846 a favorable opportunity for carrying out this programme presented itself, for, weak in character and wholly unversed in theological learning, while strongly holding the very highest views of his own prerogatives and eagerly receptive of everything which tended to exalt them further, he was exactly the instrument suited for its execution. Two experiments, to test at once how far he was prepared to go, and how far Latin Christendom was prepared to submit in the matter of decrees on faith and morals issuing from himself singly, with no previous conciliar examination or decision, were tried in 1854 by the promulgation of the tenet of the Immaculate Conception and in 1864 by that of the Syllabus of Errors. The former of these met with little resistance, the latter with none, and it was therefore judged safe to proceed with the bolder and more far-reaching scheme which they but foreshadowed. Its success appeared to be almost a foregone conclusion; for, not only could a compact and docile Italian majority be as surely reckoned on as it was at Trent, but the far larger number of Roman Catholic bishops all over the world had been virtually appointed by Pius IX. during his long pontificate, and that exclusively from the Ultramontane school. Nevertheless there was still a minority important enough to make some caution desirable in the earlier stages of the preliminaries, and the proposal to hold an œcumenical council was first laid privately before the congregation of rites by the pope himself in December, 1864, contemporaneously with the issue of the Syllabus, and immediately afterwards before all the cardinals then at Rome, who were desired to give their opinions as to the opportuneness of convoking the council at all and as to the subjects it should discuss if convoked. Nineteen cardinals approved the proposal; two opposed it; and one remained neutral. In March, 1865, a congregation of direction was formed to take further steps towards the desired end, and private communications were made to various bishops and to the nuncios at the different courts, who were asked to send competent theologians to take part in the preliminary congregations. Some communications were also made privately in 1866 to bishops of the Oriental rite. The first directly public intimation of the approaching council was made in June, 1867, through a circular letter of Cardinal Caterini to the 500 bishops present in Rome at the 18th centenary festival of the martyrdom of St. Peter and St. Paul, inviting their reply to a schedule of inquiries. In September, 1868, an invitation to attend was despatched to the Oriental bishops not in communion with Rome, and also to "Protestants and non-Catholics." But, as it was intended that no Oriental prelate should be admitted to a seat in the council till he had first made profession of the Roman Catholic system in its entirety, and as Protestants were merely to be referred to "experienced men" to convince them of their errors, the insincere invitation met with no acceptance whatever. The bull of convocation was promulged on 29th June, 1868, appointing 8th December, 1869, as the day of meeting. A few days before this latter date, 27th November, Pius IX. issued the brief *Multiplices inter*, prescribing the mode of conciliar procedure and effectually fettering the council from the outset, so that it had never even the shadow of freedom which ostensibly was allowed to the Tridentine synod. This brief consists of a preamble and ten chapters, containing, amongst much else, the following provisions: Any member desiring to bring forward a proposal had to deliver it privately in writing to a special committee named by the pope (of which there were six for various departments), and it should contain nothing foreign to the traditions of the Roman Church. Unless the committee passed it, no further action could be taken upon it. Strict secrecy as to the proceedings of the council, and even as to the opinions of particular members, was to be observed towards all outsiders. All new decrees and canons were to be discussed in preliminary congregations before the public sessions, drafts being supplied some days previously, and those who desired to speak to the questions were obliged to give notice at least a day beforehand. Priority of speech was secured for these; if others desired to speak afterwards they had to obtain the permission of the presidents, all of whom were cardinals of the court party. If little or no debate arose, the draft decrees were to be officially formulated; if there were division of opinion, the question should be referred to the subcommittee (*deputatio*) corresponding to each congregation's subject of discussion, which should decide the matter if no further difficulty were raised. All the officers of the council were named directly by the pope, and in no case elected by the council itself, which was thus deprived of several conciliar rights held previously to be inherent and indefeasible, and which had been exercised even at Trent.

The assemblage of the council was looked on with little favor by a large part of the Roman Catholic world, and in particular two German documents attested the alarm it aroused. In April, 1869, Prince Hohenlohe, Bavarian foreign minister, sent a circular letter to the European courts, warning them of the political dangers likely to ensue; and most of the German bishops, assembled at Fulda in September of that year, sent an address to the pope, anxiously deprecating the definition of papal infallibility which had been recommended in the *Civiltà Cattolica* of 6th February, 1869, to be made by the summary process of acclamation. This proposal drew forth two able books in opposition to the dogma—one which appeared anonymously (Janus) in Germany, and *Du Concile Général et de la Paix Religieuse*, by Maret, bishop of Sura and dean of theology at the Sorbonne, published in France; but they did not delay the measures being taken for its declaration.

The council assembled punctually on the appointed day, 8th December, 1869, and owing to the modern facilities of intercommunication it was by far the largest gathering of the kind in history, no fewer than 749 bishops, cardinals, abbots, and generals of orders being present,—a number afterwards increased to 764,—and including nearly three-fourths of the whole Roman Catholic episcopate. Of these it has been estimated that the minority opposed to the infallibility dogma amounted to at least 160, while in the majority were reckoned 53 bishops *in partibus*, who, as having no real dioceses, and being thus unable to attest the historical belief of their flocks, had properly no right of suffrage upon dogmatic questions in a council, such attestation being the one function dischargeable by bishops assembled in synod when considering articles of belief. To these are to be added about 125 bishops of sees too modern to have any ancient tradition to attest, such as those in North and South America, Australasia, and Oceanica, who were thus for conciliar purposes on the same footing of incompetence to speak for any one save themselves. And, besides these two large groups, there was a third, consisting of about 90 missionary bishops entirely under the control of the Propaganda, and thus not free agents, while their sees were in most cases of very recent origin, so that they also could allege only their personal opinion, having no ancient records to attest. By far the larger number in these groups were on the side of the court majority. The Italian bishops, numbering about 170, and the Spanish, 40 in number, were also infallibilists almost to a man, but included scarcely one theologian in their ranks. And no fewer than 300 of this majority were the personal guests of Pius IX., lodged, boarded, and maintained at his cost, and thus openly retained to do his bidding. The minority consisted chiefly of the German and Austrian bishops, a considerable section of Hungarian, French, and North American prelates, and many of those Orientals of the Latin Church who occupied dioceses other than mere titular and paper ones. But this minority, though composed mainly of natives of the most highly educated and intellectual countries, and containing almost every bishop of note for ability and theological learning, was by no means so compact and united as were the bishops of the majority; and there was not even full agreement amongst its members as to the grounds for opposing the new dogma, many going no further than its inopportuneness, but not entertaining deeper objections to it. Thus, even apart from its numerical inferiority, the opposition was at a disadvantage in face of the curialists, and lost not a few members to them during the progress of the council. Not only were the efforts to obtain freedom from the fetters of the brief *Multiplices inter* vain, but no member of the opposition could secure a place on any of the commissions or sub-committees, which consisted exclusively of infallibilists.

The matter of most importance in the first congregation, which was held on 10th December, 1869, was the publication of a bull, decreeing that, if the pope should die during the council, it should at once be prorogued and take no part in the election of a pontiff, which was to be restricted to the college of cardinals. The session which followed was little more than formal; but two steps towards bringing about the intended result were taken before the next time of assembling. The "theologians" were forbidden to attend any meetings of the bishops, or even to meet among themselves to discuss any conciliar matters, being restricted each to private conference with the particular bishop to whose person he was attached; and various petitions for the definition of the new dogma were drawn up and signed, one being the result of a letter to the bishops of the council, issued by Archbishop Manning and the conductors of the *Civiltà Cattolica*, and signed by some hundreds, another from the Italian prelates, a third from those of the Franciscan order, and a fourth from the Uniat Armenians, besides several of less note. The opposition issued a counter-memorial with 135 signatures; but, as it is therein admitted that papal decrees *ex cathedra* on faith and morals are irreversible, even without the consent of the church being known in any way, and that true obedience to every decree of the see of Rome is due by all Christians, no weight could attach to it as a serious plea for rejecting or even delaying the definition. The second session (6th January, 1870) was also formal only, so far as the direct transaction of business was concerned; but by the adoption of a measure causing all the members present to recite the creed of Pius IV., containing a clause professing obedience to the pope (this clause being omitted by the pope himself), and then to renew the episcopal oath of feudal submission to the Papacy, powerful pressure was brought to bear upon the weaker of the opposition, who were thus reminded how far they had pledged themselves already, and how unreasonable it therefore was to haggle about taking but one step in advance on the self-same road. The time between the second and third session was mainly occupied in preparing the drafts (*schemata*) of constitutions on the faith and on the church, and also with discussions of sundry disciplinary measures (notably as regards clerical immorality) and the preparation of a new catechism; but none of these last were proceeded with. By the pope's direct command the cardinal-presidents of the congregations issued, on 20th February, 1870, rules to check long debates, which drew yet tighter than before the cords that deprived the council of all freedom. Speakers were confined to touching upon such clauses only of any amendment as they had given previous notice of meaning to discuss, and were not allowed to take part otherwise in a debate, while the closure could be applied by the presidents at the demand of any ten members. This latter drastic measure drew out a protest from more than one hundred bishops, who urged that it was destructive of conciliar liberty (already much hampered by the noisy attempts of the infallibilists to stifle free discussion), and that the steps being taken disregarded the note of moral unanimity which should mark the decisions of a general council, thereby exposing the council itself to hostile criticism and even rejection. They pointed out several other serious faults in the new rules, but could obtain no modification of them. The constitution on the faith (usually cited now as *Dei Filius*), however—a long and far from clearly worded document,—directed chiefly against modern rationalism, and enforced by 18 canons of anathema, was completed; it passed the congregation without difficulty, was signed by all the 667 members present, and was published in the third session, 24th April, 1870, with papal confirmation, or rather in the unprecedented form of a proclamation by the pope singly, "the sacred council approving,"—an innovation which was intended to mark it as solely his act, and to settle in this summary manner the long-standing controversy as to the relative superiority of popes and councils. There were few, however, even of the opposition, who cared to contest such a point, and there was nothing of a contentious nature, as regards the two parties in the council, in the constitution itself, so that no debate was raised upon it.

The real struggle was yet to come, namely, over the constitution on the church, into which the new dogma was to be introduced. This constitution (now usually cited as *Pastor Æternus*) asserted the following propositions: (1) that a proper primacy of jurisdiction over the whole church was conferred upon St. Peter directly and singly, and not mediately through any delegation to him, as chief minister in the church, of a primacy held by the church corporately; (2) that this Petrine primacy vests by divine institution and right in the line of Roman pontiffs; (3) that the pope's jurisdiction is immediate in all churches—*i.e.*, he is the universal ordinary, the actual bishop of every see (all other bishops being merely his curates and deputies), and is not a remote or merely appellate authority—so that in questions not of faith and morals alone, but of discipline and government also, all the faithful of whatever rite or dignity, both pastors and laity, are bound, individually and collectively, to submit themselves thereto; (4) that it is unlawful to appeal from the judgments of the Roman pontiffs to an œcumenical council, as though to a higher authority; and (5) that the Roman pontiff, when he speaks *ex cathedra*, and defines a doctrine of faith or morals to be held by the universal church, is infallible, and such definitions are accordingly irreformable of themselves, and not from the consent of the church. This document was voted upon in the congregation of 13th July, 1870, consisting of 671 members. Of these 451 voted in the affirmative; 88 voted against it; 62 voted *placet juxta modum*, meaning that they would accept it if it were seriously modified; and 70 did not vote at all. By the canonical theory of councils such a division of opinion as this voided the decision of the majority, and made it null. For, while a bare majority in a council suffices to pass a mere disciplinary canon, being a variable matter, contrariwise, to enact a dogmatic decree requires practical unanimity, since nothing can be imposed as of faith for which the two attesting notes of universal prevalence and historical continuity cannot be adduced. And, as the dissent of any appreciable number of members denotes that they do not know it as the local tradition of their several dioceses, it thereby destroys the claim to these notes. Not only so; but in view of the character in which bishops appear at councils, as representing their laity, it is clear that the size and population of their several dioceses have to be taken into account when estimating the weight attaching to their individual testimony as to the reception of any dogma within their jurisdictions. Tried by this standard, the opposition was very much more important than its muster-roll seems to indicate, for it included the bishops from many of the most populous Roman Catholic dioceses, such as the archbishops of Paris, with 2,000,000 Catholics, Breslau with 1,700,000, Cologne with 1,400,000, Vienna with about the same number, and Cambrai with 1,300,000; whereas 62 bishops of the Papal States, for example, represented no more than 700,000 altogether, apart from the hundred and more titulars, who had no flocks at all. This matter may be summed up thus: every vote cast for the new dogma stood for 142,570 lay folks; but every vote cast against it stood for 492,520. Nor is this all: a council claiming to be œcumenical must speak with the consent of both East and West. But, even if the very large concession be made that the Uniat churches in communion with Rome are in truth the lawful representatives of the ancient Oriental Church, the fact remains that the number and rank of the Orientals in the minority was such as to make the vote at best only a Latin one. The Melchite and Syrian patriarchs of Antioch, the Chaldee patriarch of Babylon, the Melchite archbishop of Tyre, the Maronite archbishops of Tyre and Sidon, of Beyrout, and of Aleppo, with several others, were in one or other of the three groups of dissentients, and thus nullified the Eastern suffrages in the majority. Immediately after this preliminary voting nearly all the bishops of the minority abruptly quitted Rome, after previously lodging a protest against the proceedings. Their flight was prompted by fears for their personal safety. They were given to understand that each of them would have two papers tendered to him for his signature in the ensuing session, one being a profession of adhesion to the infallibility dogma, the other a resignation of his diocese in case he refused such adhesion. And they had good reason to think that the pope, who had declared that he meant to be proclaimed infallible "without limitation" (*senza condizione*), and had shown open enmity to more than one of their number, would employ direct coercion in the event of continued resistance, bringing his temporal power as sovereign of Rome to bear on the rebels within his territory. Accordingly when the public session was held on 18th July, 1870, while 535 bishops voted for the constitution *Pastor Æternus*, only two, those of Ajaccio and of Little Rock,[1] remained to utter their "non-placet." The pope thereupon confirmed the decree, and the proceedings virtually ended.

By one of the most singular of historical coincidences, on that very day Napoleon III. proclaimed war against Prussia, and entered on that great conflict amongst the immediate results of which were the overthrow of the temporal power of the Papacy and the occupation of Rome by the troops of the king of Italy in two months' time from the last meeting of the council. It was formally prorogued by Pius IX. on 20th October, and is thus technically still in existence; but the prorogation is a virtual dissolution.

The opposition collapsed everywhere after the promulgation of the decree, as even the German bishops, who had been the mainstay of the minority, consented to publish it in their dioceses. This led to the genesis of the Old Catholic communion (see OLD CATHOLICS) as a refuge for such as were conscientiously unable to accept the new dogma, but equally unwilling to join any of the Protestant societies. But submission to the dogma is not identical with belief in it, at any rate in the sense wherein Pius IX. understood it and meant it to be received. The majority had, indeed, achieved their "triumph over history": they had done what warning voices had declared beforehand to be their purpose—annihilated the independence of the episcopate, abrogated the teaching and attesting functions of the dispersive church, and contracted the Roman Catholic creed into the single article of belief in the pope. But they had failed in three matters essential to the ultimate success of their plans. They had not even seemed to make any reply, save that of their superior voting strength in the council, to the destructive criticism which had established the falsehood and novelty of the infallibility dogma; they were not able to pass it so as to be canonically or theologically binding; and they could not secure its unqualified acceptance in its original form. Instead of terminating all controversy, the new dogma (as might have been anticipated by any one familiar either with the laws of the human intellect or the facts of ecclesiastical history) at once became itself a topic of debate, receiving contradictory interpretations, partly due to its vague and clumsy wording, and partly the expression of competing opinions, ranging from the widest to the narrowest view of its scope and force. The "senza condizione" of Pius IX. proved hopelessly unworkable, and it was soon found necessary to modify the decree so as to make it a not intolerable burden for intelligent consciences. Accordingly, Bishop Fessler of St. Pölten, secretary-general of the council, published in 1871, with a brief approbation from the pope, his treatise *Die wahre und falsche Unfehlbarkeit der Päpste*, soon reproduced in French and English, which provides that "juxta modum" limitation vainly sought from the tyrannical majority in the council itself. Ostensibly a reply to an anti-infallibilist work by the learned canonist Von Schulte, it is in fact a studious minimizing of the incidence of the dogma, arguing that the occasions when the attribute of papal infallibility has been actually exercised and formulated in *ex cathedra* decrees have been, and must continue to be, of extremely rare occurrence, and further attenuating the dogma itself, so as to approach in some measure the old Gallican view of the pope's constitutional and limited authority as official spokesman of the church. In England, where the evidence collected by Pitt in the 18th century, and by the earl of Liverpool in the 19th, when aiming at the abolition of the penal laws, on the opinions held by Roman Catholic theologians as to the prerogatives and attributes of the popes, made their general repudiation of papal infallibility familiarly known, the question was even more trenchantly dealt with. For Dr. Newman, who had anxiously deprecated the coming definition, speaking of it in a letter to Bishop Ullathorne as a "great calamity," wantonly forced on by "an aggressive, insolent faction," explained the manner of his own belief and acceptance of it in a letter to the duke of Norfolk, and that in terms which to less subtle (and, it may be, more practical) intellects are indistinguishable from disbelief and rejection. Not only does he limit the attribute itself, and the occasions of its exercise, within much straiter bounds than those set by Fessler, but he specifies a number of cases wherein he would disobey a papal mandate, and, after saying that each such mandate must be decided on its own merits, adds: "I should look to see what theologians could do for me, what the bishops and clergy around me, what my confessor, what friends whom I revered; and if, after all, I could not take their view of the matter, then I must rule myself by my own judgment and my own conscience." That this deliverance is in effect a complete evacuation of the dogma will appear at once by supposing cognate language to be used in the civil sphere by the subject of an absolute temporal sovereign when defining the limits of his allegiance. But the subsequent elevation of its author to the cardinalate proves that his view is regarded as fairly tenable in the Roman Church, and the infallibility dogma is thus, for the present at least, dismissed from the domain of practical action to that of speculative theory.

The bibliography of the Vatican Council is very copious, but the following works will suffice for most students to consult: Cecconi, *Storia del Concilio Vaticano*, Rome, 1873; J. Friedrich, *Geschichte des vatikanischen Konzils*, Bonn, 1877-87; Id., *Tagebuch, während des vaticanischen Concils geführt*, Nördlingen, 1873; Id., *Documenta ad Illustrandum Concilium Vaticanum*, Nördlingen, 1873; Quirinus, *Römische Briefe vom Concil*, 1870 (also an English version); Pomponio Leto, *Otto Mesi a Roma durante il Concilio Vaticano*, Florence 1873 (also an English version); Michelis, *Kurze Geschichte des vatican-*

---

[1] [These bishops should be Riccio of Caiazzio and Fitzgerald of Little Rock, Arkansas, U. S. The last was Edward Fitzgerald (b. 1838), of Limerick, Ireland, who went from the Emmitsburg Seminary to Columbus, Ohio, as rector, and thence to Arkansas in 1867 as bishop, whither he attracted many Catholic emigrants and extensively promoted the interests of his church.—AM. ED.]

VATTEL, Emer de, or Emmerich von (1714–1767), an eminent jurist, was the son of a Protestant minister, and was born at Couvet, in the principality of Neuchâtel, on 25th August, 1714. He studied at Basel and Geneva. During his early years his favorite pursuit was philosophy; and, having carefully examined the works of Leibnitz and Wolf, he published in 1741 a defence of Leibnitz's system against Crousaz. In the same year Vattel, who was born a subject of the king of Prussia, repaired to Berlin in the hope of obtaining some public employment from Frederick II., but was disappointed in his expectation. Two years later he proceeded to Dresden, where he experienced a very favorable reception from Count Brühl, the minister of Saxony. In 1746 he obtained from the elector, Augustus III., the title of councillor of embassy, accompanied with a pension, and was sent to Bern in the capacity of the elector's minister. His diplomatic functions did not occupy his whole time and much of his leisure was devoted to literature and jurisprudence. Among other works he published *Loisirs Philosophiques* (1747) and *Mélanges de Littérature, de Morale, et de Politique* (1757). But his reputation chiefly rests on his *Droit des Gens, ou Principes de la Loi Naturelle appliqués à la Conduite et aux Affaires des Nations et des Souverains* (Neuchâtel, 1758). During the same year he was recalled from Switzerland, to be employed in the cabinet of Dresden, and was soon afterwards honored with the title of privy councillor. His labors now became so intense as to exhaust his strength, and his health broke down.. After a period of rest he returned to Dresden in 1766; but his renewed exertions soon produced a relapse, and he made another excursion to Neuchâtel, where he died on 20th December, 1767. His last work was entitled *Questions de Droit Naturel, ou Observations sur le Traité du Droit de la Nature, par Wolf* (Bern, 1762).

Vattel's *Droit des Gens*, which is founded on the works of Wolf, had in its day a great success, in truth, greater than it deserved. His principal and only merit consists in his having rendered the ideas of that author accessible to the political and diplomatic world. The *Droit des Gens* passed through many editions, and was translated into various languages (English in 1760).

VAUBAN, Sebastien Le Prestre De (1633–1707), marshal of France, was born in the neighborhood of Saulieu in Burgundy (now in the department of Côte-d'Or) on 15th May, 1633. At an early age he was left an orphan in very poor circumstances, and his boyhood and youth were spent among the peasantry of his native place, thus enabling him to gain that sympathetic insight into the condition of the agricultural classes which he afterwards showed in his economic writings. He owed his early education and his first instruction in the rudiments of mathematics and surveying to a friendly curé, who had taken an interest in him and discerned his abilities. At the age of seventeen he joined the Spanish troops under the prince of Condé, but after about a year's campaigning was taken prisoner by the French. He then became known to Mazarin, who treated him with kindness and enlisted him in the service of the king. In 1653 he first earned repute as an engineer by the share he had in the capture of Sainte-Menehould, and after further distinction at Stenay and Clermont he was given a lieutenancy, and received in 1655 his commission as an "ingénieur du roi." Between that year and the peace of 1659 he took part in numerous successful sieges—especially those of Gravelines, Ypres, and Oudenarde. After the cession of Dunkirk, Fort Louis, and Mardyke in 1662, he had charge of the work of fortifying them as frontier towns. On the renewal of war in 1667, he saw much service in Flanders, and gained special distinction in the siege of Lille, of which town he ultimately became governor, the king making him a lieutenant in the guards and bestowing on him a pension. The originality and success of his methods were now fully recognized, and in 1669 he drew up, at the instance of Louvois, his first exposition of the theory of fortification (*Mémoire pour Servier d'Instruction dans la Conduite des Siéges*), which was afterwards published at Leyden (1740). In 1673, Vauban accompanied Louis XIV. on his Dutch campaign, and directed the more important sieges, afterwards superintending the demolition or reconstruction of the captured places. In the following year, his principal achievement was the capture of Maestricht, and in 1677, he had the chief credit for the fall of Valenciennes and Cambrai. In the latter year, he was appointed commissary-general of fortifications in succession to Clerville, and thus gained an opportunity, which in the following year he diligently used, for practically reconstructing the entire land-defences of France. In the short war of 1683–84, he gained further distinction by the fall of Luxembourg, and during the campaign of 1691–92, the names of Mons and Namur were added to the long list of his successes. In 1686, Vauban had the courage to make a representation to the king in favor of the republication of the Edict of Nantes; and about 1697, he wrote his almost equally bold *Projet d'une Dixme Royale*, which, however, was not published until 1707 (see Political Economy, vol. xix. p. 372). In 1693, he was made a grand cross of the order of St. Louis, and in 1703 marshal of France. The close of his life, which was saddened by the consciousness of waning influence and failing health, he devoted largely to the arrangement of the voluminous manuscripts (*Mes Oisivetés*) which contained his reflections on such subjects as the art of war, administration and finance, agriculture, commerce, and the like. He died at Paris, on 30th March, 1707.

For Vauban's work as a military engineer, see Fortification (vol. ix. p. 392–4). The *Oisivetés* long remained unpublished, and of the twelve manuscript volumes containing them several seem to have been hopelessly lost; the fragmentary remains were published in three volumes at Paris in 1841–43. The *Traité de l'Attaque des Places*, written in 1703, and that *De la Défense des Places*, written a few months before his death, were published together in 1737. Among the subjects in which Vauban took a lively interest, and on which he wrote memoirs, may be mentioned the fortification of Paris, the inland navigation of France, its army organization, especially in the artillery service, and the limits of ecclesiastical power in temporal matters. The introduction of the socket-bayonet into the French army is usually ascribed to Vauban.

VAUCLUSE, a department of France, formed in 1793, out of the county of Venaissin (695 square miles), the principality of Orange (62½ square miles), and a part of Provence (515½ square miles), lies between 43° 39′ and 44° 26′ N. lat. and 4° 38′ and 5° 45′ E. long., is bounded by Drôme on the N., Basses-Alpes on the E., Bouches-du-Rhône (from which it is separated by the Durance) on the S., and Gard and Ardèche (from which it is separated by the Rhone) on the W. It has also an enclave, the canton of Valréas, in the department of Drôme. The western third of Vaucluse belongs to the Rhone valley, and consists of the rich and fertile plains of Orange, Carpentras, and Cavaillon. To the east, with a general west-south-west direction and parallel to one another, are the steep barren ranges of Ventoux, Vaucluse, and Lubéron, consisting of limestones and sandstones. The first-mentioned, which is the most northerly, has a maximum elevation of 6273 feet; the culminating peak, on which is a meteorological observatory, is isolated and majestic. The Vaucluse chain does not rise above 4075 feet. The most southerly range, that of Lubéron (3691 feet), is rich in palæontological remains of extant mammals (the lion, gazelle, wild boar, etc.).

The Rhone is joined on the left by the Aygues, the Sorgue (rising in Petrarch's celebrated fountain of Vaucluse, which has given its name to the department), and the impetuous Durance. The Sorgue has an important tributary in the Ouvèze and the Durance in the Coulon (or Calavon). These and other streams feed numerous irrigation canals; their channels are sometimes quite dry in summer. The climate is that of the Mediterranean region. The valley of the Rhone suffers from the mistral (see vol. ix. p. 447); but the other valleys are sheltered by the mountains, and produce the oleander, pomegranate, olive, jujube, fig, and other southern trees and shrubs. The mean annual temperature is 55° Fahr. at Orange and 58° at Avignon; the extremes of temperature are 5° and 105° Fahr. Snow is rare. The south wind, which is frequent in summer, brings rain. The average annual rainfall is 29 inches in the hill region and 22 in the plains.

Of the total area of 881,610 acres 679,737 are cultivated, —cereals occupying 232,250 acres, market and other gardens 41,085, meadows, pastures, and orchards 89,950, industrial vegetable products 18,993, summer fallows 58,489, vines 24,699, and woods and forests 197,049. The live stock in 1880 included 11,412 horses, 16,602 mules, 4410 asses, 2079 head of cattle, 46,406 pigs, 11,660 goats, and 165,040 sheep of native and 6983 of improved breed. There were 11,701 beehives (104 tons of honey and 23 tons of wax). Amongst wild animals, the otter and beaver occur along the bank of the Rhone. The crops in 1884 were returned as follows —2,151,385 bushels of wheat, 7309 of meslin, 39,476 of rye, 60,208 of barley, 1677 of buckwheat, 17,162 of maize, 240,850 of millet, 445,920 of oats, 4,247,600 of potatoes, 21,680 tons of beet-root, and 197 tons of tobacco. In 1880, early vegetables were produced to the value of £384,940 [$1,870,808.40], and stone fruit to the value of £13,341 [$64,837.26]. The olive crop amounted to 233,928 bushels (622 tons 17 cwts. of oil). In 1884, 4,779,236 gallons of wine were obtained (average for preceding ten years, 2,562,384 gallons). In the same year, 766 tons of silk cocoons were produced. The phylloxera has reduced the area of the vineyards from 79,000 to 13,000 or 14,000 acres; American vines are now being introduced. The culture of madder and the mulberry is diminishing, while the Chinese grass-cloth plant, beetroot, sorghum, and millet are grown in increasing quantities. The truffle markets of Carpentras and Apt are important. Lignite and coal (11,382 tons in 1882), iron, and sulphur are mined; rich deposits of plaster, stone, clay, and ochre are worked; and there is a large variety of mineral springs. The chief industrial establishments are manufactories of madder dye, silk-mills (4295 workmen), silk-spinning factories (3365 spindles and 411 workmen), oil-mills, flour-mills, paper-mills (1047 workmen and 2700 tons of paper in 1880), wool-spinning factories (2645 spindles and 369 workmen), confectionery establishments, manufactories of pottery, earthenware, bricks, mosaics, tinned provisions, chemicals, candles, soap (2500 tons in 1880), and hats, breweries, puddling works, iron and copper foundries, cabinet workshops, blast furnaces, saw-mills, edge-tool workshops and nursery gardens. Coarse cloth, carpets, blankets, and ready-made clothes are also produced. Vaucluse has 135 miles of railway, 97 of national roads, and 2380 of other roads. The population increased by 74,670 between 1801 and 1865, but from that date to 1886 it diminished by 24,304, owing to the decay of the madder and wine industries. In 1881, the department had 244,149 inhabitants, and in 1886, 241,787. Vaucluse forms the archiepiscopal diocese of Avignon, has its court of appeal at Nîmes, and belongs to the Marseilles army corps. It is divided into 4 arrondissements (Avignon, chef-lieu of the department, with 35,355 inhabitants in 1886; Apt, 4293; Carpentras, 8563; and Orange, 6904), 22 cantons, and 150 communes. Cavaillon (5164 inhabitants) is famous for its early vegetables and its fruit. Vaison (1988 inhabitants) is rich in Roman remains, and possesses an interesting cathedral and a ruined castle of the counts of Toulouse.

VAUD (Germ. *Waadt*), a canton of Switzerland, ranking as nineteenth in the Confederation, takes its name either from the German *Wald* (a wood) or, more probably, from *Wälsch*, the term applied by Teutonic to non-Teutonic tribes. It is of very irregular shape, as it owes its existence solely to historical causes. Roughly speaking, it includes the whole north shore of the Lake of Geneva. It stretches on the southeast as far as St. Maurice and takes in Château d'Oex, while to the northwest the Jura and the Lake of Neuchâtel are its boundaries. The district of Avenches (entirely surrounded by the canton of Freiburg) and a long narrow tongue running up to Payerne are also within its boundaries. The total area is 1244.3 square miles, larger than that of any other Swiss canton except Graubünden (Grisons), Bern, and Valais. Of this total 1053.6 square miles are classed as productive, forests occupying 282 and vines 24.8 square miles. This is a larger extent under vines than in any other canton save Tessin (Ticino), and more than one-fifth of the total wine-growing districts in the whole Confederation. Of the unproductive portion lakes occupy 164.1 and glaciers 4.3 square miles, while towns and buildings cover 5.7. The highest point is the Diablerets (10,667 feet) in the southeast corner. The population in 1880 amounted to 238,730 (an increase of 7030 since 1870), a larger number than in any other canton except Bern and Zurich. Of these 212,164 are French-speaking, 21,692 German-speaking (many persons from the German-speaking cantons coming thither to learn French), and 2518 Italian-speaking. In religion, 219,427 are Protestants (Calvinists), divided between the "national church" (19.20) and the "free church" (1.20). The capital is Lausanne (30,179 inhabitants, or with the surrounding districts 37,427) which since 1874 has been the seat of the federal tribunal. It is the largest town in the Confederation after Zurich, Basel, Geneva, and Bern. Other important places are Vevay (7820 inhabitants) and Yverdon (5968).

Agriculture is the main occupation of the people; the land is much subdivided and very highly cultivated. The vineyards employ 20,000 persons. About one-third of the wine produced is exported, the best known varieties being Yvorne (white) and Cortaillod (red). There is not much industry, except that of the watchmakers in the Jura; and the commerce is comparatively unimportant. Many foreigners reside in the canton, particularly on the shores of the Lake of Geneva, from Lausanne to Villeneuve (as formerly Gibbon, Voltaire, and Rousseau). Montreux is a favorite winter residence, and its growth may be judged of from the fact that its inhabitants increased from 3211 in 1849 to 4379 in 1860, 6659 in 1870, and 8017 in 1880, the increase being specially marked since the opening of the railway in 1861. The railways are 168 miles in length, besides a "ligne régionale" on the high road from Lausanne to Échallens, and the cable railways from Lausanne to Ouchy and from Territet to Glion. In educational matters the canton holds a high place. The academy of Lausanne dates from 1537; and there are a very large number of schools and educational establishments at Morges, Lausanne, Vevay, and elsewhere. Pestalozzi's celebrated institution flourished at Yverdon from 1805 to 1825. Among the remarkable historical spots in the canton are Avenches (the chief Roman settlement in Helvetia), Granson (scene of the famous battle in 1476 against Charles the Bold), and the castle of Chillon (where Bonnivard, the prior of St. Victor at Geneva, was imprisoned from 1531 to 1536 for defending the freedom of Geneva against the duke of Savoy).

History.—The early history of the main part of the territories comprised in the present canton is identical with that of southwest Switzerland generally. The Romans conquered (58 B.C.) the Celtic Helvetii, and so thoroughly colonized the land that it has remained a Romance-speaking district, despite conquests by the Burgundians (5th century) and Franks (532) and the incursions of the Saracens (10th century). It formed part of the empire of Charlemagne, and of the kingdom of Transjurane, Burgundy (888–1032), the memory of "good queen Bertha," wife of King Rudolph II., being still held in high honor. On the extinction of the house of Zäringen (1218) the counts of Savoy gradually won the larger part of it, especially in the days of Peter II., "le petit Charlemagne" (died 1268). The bishop of Lausanne (to which place the see had been transferred from Aventicum by Marius the Chronicler at the end of the 6th century), however, still maintained the temporal power given to him in 1011 by the king of Burgundy, and in 1270 became a prince of the empire. (We must be careful to distinguish between the present canton of Vaud and the old mediæval Pays de Vaud: the districts forming the present canton very nearly correspond to the Pays Romand). In the 15th century Bern began to acquire lands to the south from the dukes of Savoy, and it was out of those conquests that the canton was formed in 1798. In 1475 she seized Aigle, in 1475–76 (in concert with Freiburg) Échallens and Granson as well as Orbe (the latter held of the duchy of Burgundy). Vaud had been occupied by Bern for a time (1475–76), but the final conquest did not take place till 1536, when both Savoyard Vaud and the bishopric of Lausanne were overrun and annexed by Bern (formally ceded in 1564), who added to them (1555) Château d'Oex, as her share of the domains of the debt-laden count of Gruyères in the division of the spoil she made with Freiburg. In 1565 the liberties of Vaud were, by a special treaty, placed under the guarantee of France. Bern in 1526 sent Farel, a preacher from Dauphiné, to carry out the Reformation at Aigle, and after 1536 the new religion was imposed by force of arms and the bishop's residence moved to Freiburg (permanently from 1663). Thus the whole land became Prostestant, save the district of Échallens. Vaud was ruled very harshly by bailiffs from Bern. In 1588 a plot of some nobles to hand it over to Savoy was crushed,[1] and in 1723 the enthusiastic idealist Davel lost his life in an attempt to raise it to the rank of a canton. Political feeling was therefore much excited by the outbreak of the French Revolution, and a Vaudois, F. C. de la Harpe, an exile and a patriot, persuaded the Directory in Paris to march on Vaud in virtue of the rights conferred by the treaty of 1565. The French troops were received enthusiastically, and the "Lemanic republic" was proclaimed (January, 1798), succeeded by the short-lived Rhodanic republic, till in March, 1798, the canton of Leman was formed as a district of the Helvetic republic. This corresponded precisely with the present canton minus Avenches and Payerne, which were restored to it in 1803. The new canton was thus made up of the Bernese conquests of 1475, 1475–76, 1536, and 1555. The constitutions of 1803 and 1815 favored the towns and wealthy men, so that an agitation went on for a radical change, which was effected in the constitution of 1831. Originally acting as a mediator, Vaud finally joined the anti-Jesuit movement (especially after the Radicals came into power in 1845), opposed the Sonderbund, and accepted the new federal constitution of 1848, of which Druey of Vaud was one of the two drafters. From 1839 to 1846 the canton was distracted by religious struggles, owing to the attempt of the Radicals to turn the church into a simple department of state, a struggle which ended in the splitting off of the "free church." The cantonal feeling in Vaud is very strong, and was the main cause of the failure of the project of revising the federal constitution in 1872, though that of 1874 was accepted. In 1879 Vaud was one of the three cantons which voted (though in vain) against a grant in aid of the St. Gotthard Railway. In 1882 the Radicals obtained a great majority, and in 1885 the constitution of. 1861 was revised. The Government consists of a great council (one member to every 300 electors) for legislative and a council of state of 7 members (chosen by the great council) for executive purposes. 6000 citizens can compel consideration of any project by the legislature ("initiative," first in 1845), and the *referendum* exists in its "facultative" form, if demanded by 6000 citizens, and also in case of expenditure of over a million francs. Capital punishment was abolished in 1874. The canton has lately been passing through serious financial difficulties. In 1862 the southwest frontier was slightly altered in consequence of a dispute with France as to the valley of Dappes.

See A. Verdeil, *Histoire du Canton de Vaud* (2d ed., 4 vols.), and L. Vulliemin, *Le Canton du Vaud* (3d ed., 1885.)

VAUDOIS. See WALDENSES.

VAUGHAN, HENRY (1621–1693), called "the Silurist," poet and mystic, was born into an ancient Welsh family settled at Skethiog-on-Usk, in the parish of Llansaintfraed, Brecknockshire, in 1621. From 1632 to 1638 he and his twin brother Thomas were privately educated by the rector of Llangattock, and then they proceeded to Jesus College, Oxford. At what time Henry left the University is not known; but it was evidently after he had studied for some time in London and had been introduced into the society of men of letters that he printed his first volume, *Poems, with the Tenth Satire of Juvenal Englished* (1646). Of this publication he was afterwards, very needlessly, ashamed. Vaughan presently became a physician and returned to his native country, first for a while practicing in the town of Brecon, and then settling down for the remainder of his life in Skethiog. From this place he sent forth his collection of sacred poems, *Silex Scintillans*, in 1650, of which a second part appeared in 1655, and the secular poems of his *Olor Iscanus*, prepared for the press in 1647, and published without his consent by his brother Thomas in 1651. A mystical treatise in prose, *The Mount of Olives*, followed in 1652, and then two prose translations, *Flores Solitudinis*, 1654, and *Hermetical Physick*, 1655. The world took little notice of these performances. In 1678 an Oxford friend collected the miscellaneous verses of Vaughan's middle life in a volume entitled *Thalia Rediviva*. Henry Vaughan died at Skethiog on 23d April, 1693, and lies buried in the churchyard of Llansaintfraed.

As a poet Vaughan comes latest in the so-called "metaphysical" school of the 17th century. He is the most remote of the disciples of Donne, and follows him mainly as he saw him reflected in George Herbert. He analyzes his experiences, amatory and sacred, with excessive ingenuity, striking out, every now and then, through his extreme intensity of feeling and his close though limited observation of nature, lines and phrases of marvellous felicity. He is of imagination all compact, and is happiest when he abandons himself most completely to his vision. His verse is apt to seem crabbed and untunable in comparison with that of Crashaw, and even of Herbert at his best. "The Retreat," with its Wordsworthian intimations, "The World," mainly because of the magnificence of its opening lines, and "Beyond the Veil" are by far the most popular of Vaughan's poems and represent him at his best. His passion for the Usk, and his desire to immortalize that pastoral river, are pathetically prominent in his writings. His metrical ear was not fine, and he affected, almost more than Herbert himself, tortured and tuneless forms of self-invented stanza.

The earlier works of Henry Vaughan, in prose and verse, were collected in a very limited private edition in four volumes, in 1871, by Dr. A. B. Grosart. The Rev. H. F. Lyte edited the sacred poems alone in 1847, up to which time Vaughan was practically unknown as a poet.

VAUGHAN, THOMAS (1621–1665), "the Rosicrucian," was the twin brother of Henry VAUGHAN (see above). When Thomas left Oxford he went into the church and became rector of his native parish Llansaintfraed until his ejectment, when he settled at Oxford as an alchemist. He died at Albury, on 27th February, 1665, poisoned by the fumes of a cauldron. Under the pseudonym of Eugenius Philalethes, Thomas Vaughan produced eleven volumes defending and describing the tenets of the Rosicrucians. The titles of these—among which are *The Man-Mouse*, 1650; *The Second Wash*, 1651; *The Fame and Confession of the Fraternity of the Rosy Cross*, 1652; *Aula Lucis*, 1652; and *Euphrates*, 1653—are not more extraordinary than their style. Henry More the Platonist engaged in controversy with Thomas Vaughan, deep calling unto deep in pamphlets.

VAUQUELIN, LOUIS NICOLAS (1763–1829), French analytical chemist, was born at Saint-André-d'Hébertot in Normandy, on 16th May, 1763. His parents, although very poor, sent him to school to fit him for the coveted post of a gentleman's servant at the château. At the age of thirteen or fourteen Vauquelin went to Rouen as laboratory boy with an apothecary. He did not remain long there; but his interest in chemistry was fairly aroused, and he began to make experiments and take notes. His master, finding him so engaged on one occasion, tore up his note-book and ordered him to keep to his menial work for the future. Vauquelin had spirit enough to resent this treatment: he borrowed six francs [$1.16] from a friend and walked to Paris to seek his fortune. For a time his prospects were very dark: after getting and losing two situations he became ill, was sent to the public hospital, and when convalescent found himself once more without money or friends. At length, however, he met a humane apothecary, Cheradame, who took him in and treated him with kindness. Vauquelin at once resumed his studies, and devoted every spare minute to learning. Cheradame introduced him to Fourcroy, who had himself worked his way up from poverty, and from this time Vauquelin's fortune was made. Henceforward he devoted his attention to chemical analysis without intermission or variety until his death, which occurred at his birthplace on 14th November, 1829. At first his work appeared as that of his friend and patron, then in their joint names; but in 1790 he commenced to publish on his own authority, and wrote perhaps more papers than any other chemist has ever done. Either together or successively Vauquelin held the offices of inspector of mines, professor at the School of Mines and at the Polytechnic School, assayer of gold and silver goods, professor of chemistry in the College of France, member of the Council of Industry and Commerce, commissioner on the pharmacy laws, examiner to the Polytechnic School, and, finally, was successor to Fourcroy himself; at this last step all the other candidates retired in his favor.

---

[1] [For Cromwell's interference and Milton's commemoration of the Vaudois religious massacres in 1655, see WALDENSES, *infra*, and vol. xvi. pp. 345–6.—AM. ED.]

Vauquelin's life was uneventful; his nature was quiet and retiring; he never desired to mix with the world; and even in the turmoil of the Revolution his interest centred in the laboratory. He was emphatically one who lived for his work alone. He never married. He does not appear to have communicated with his parents after he became wealthy. The one bright feature in the somewhat colorless character of his later life was the fact that he supported Fourcroy's aged sisters after his old friend died.

As an analyst Vauquelin came at the right time. The theory of chemistry was being built afresh on a basis of experiment; all substances, natural and artificial, were being classified by their composition; and it would be hard to mention any mineral or any plant or animal or product of life that Vauquelin did not examine. With Fourcroy he drove the piles on which the first theories in pure chemistry were founded; with Haüy he put mineralogy on a satisfactory footing; but he himself was neither chemist nor mineralogist. Vauquelin's name is associated with 376 papers published between 1790 and 1833, and, with the exception of one or two criticisms and claims for priority, these were all simple records of patient and laborious analytical operations. He propounded no theories, was guided by no generalizations, and was troubled by no problems save those of his methods. Given a substance, he did his best to find its composition, devising new processes where these seemed necessary, but this was all. Considering the amount of work he did, one is surprised that only two new elements are associated with his name. He detected glucina in beryl when analyzing that mineral for Haüy, and in a red lead ore from Siberia he discovered chromium, although, strange to say, eight years elapsed between his first examination of the ore and his separation of chromic acid. It is even more extraordinary that he never suspected the existence of alkaloids in the vegetable and animal juices he was continually analyzing. Cuvier in his *éloge* argues from this that without the concurrence of a happy chance the greatest perseverance and the most admirable patience often miss the mark; a more legitimate inference might be that work carried on "for work's ignoble sake" is fruitless in higher results, and that perseverance apart from a definite aim can accomplish little.

VAUVENARGUES, Luc de Clapiers, Marquis de (1715–1747), a moralist and miscellaneous writer of considerable originality and power, was born at Aix in Provence on 6th August, 1715. His family was poor though noble; he was very badly educated; and his health was weak. He, however, entered the army early and served for more than ten years, taking part in the Italian campaign of 1736, and in the disastrous expedition to Bohemia six years later in support of Frederick the Great's designs on Silesia, in which the French were abandoned by their ally. Vauvenargues suffered greatly from the hardships of Belle-Isle's winter retreat, and indeed never recovered from them. He was also much troubled by his poverty and in a private letter written to a very intimate friend he discusses the possibility of obtaining a loan from a certain rich acquaintance by undertaking, first to get his son into his own regiment, or secondly to marry one of his daughters within a short time and with only a reasonable dowry. Nevertheless Vauvenargues was, according to the standard of that time, a most honorable man. Indeed he seems to have pushed honor to the point of naïvety, if it be true that, weary of waiting for promotion, he addressed himself, not to any minister, or, more wisely still, to some favorite, but to the king himself. This unsophisticated proceeding had of course no result, and Vauvenargues threw up his commission, hoping—but unsuccessfully—to obtain a post in the diplomatic service. His ill-luck pursued him: for, having joined his family in Provence, he fell ill with a bad form of smallpox, which still further weakened him. This was in 1744. He had, besides the correspondence above referred to with a certain M. de Saint Vincens, maintained one, still more interesting and likewise only recently known, with the celebrated and eccentric Marquis de Mirabeau, the author of *L'Ami des Hommes*, the father of the great Mirabeau. He had also, when in garrison at Nancy, begun an exchange of letters with Voltaire, who had a very high opinion of him, and this, with his natural inclinations, determined him to literature. He published in 1746 an *Introduction à la Connaissance de l'Esprit Humain*, with certain *Réflexions* and *Maximes* appended. He died of lung disease at Paris on 28th May, 1747.

The bulk of Vauvenargues's work is very small, but its interest is very considerable. In the *Introduction*, in the *Réflexions*, and in the minor fragments it consists, in fact, of detached and somewhat desultory thoughts, in the style wherein the 18th century so much delighted, on questions of moral philosophy and of literary criticism. Sainte-Beuve has mildly said that as a literary critic Vauvenargues "shows inexperience." It would be truer to say that this part of his work has no value or interest beyond that of curiosity. He had no knowledge of any language but his own, and his literary criticism is limited to a repetition in crude form of the stock ideas of his time. Thus he exaggerates immensely the value of Racine and Boileau, but depreciates Corneille and even Molière. It is almost sufficient to say that he blames Molière for choosing "des sujets si bas," and shows an entire ignorance of all French literature before the 17th century, and of all other literature whatsoever, except a certain second-hand acquaintance with the classics. As a writer he stands far higher. His style is indeed, according to strict Academic judgment, somewhat incorrect, and when he attempts rhetorical flourishes (which is not often) they have usually the artificial and affected character—stilted or namby-pamby—which mars so much 18th century work. His strength, however, is not really in any way that of a man of letters, but that of a moralist. Even here he is not superior to the weaknesses of his time. In his day the anti-religious or anti-Christian movement of thought was not fully declared, and he did not adopt the complete *philosophe* attitude; in his letters, at any rate, he poses somewhat ostentatiously as "neutral" between the religious and the anti-religious school. In some of his maxims about politics there is also traceable the hollow and confused jargon about tyrants and liberty which did so much to bring about, and to embitter when brought about, the struggles of the Revolution. It is in morals proper, in the discussion and application of general principles of conduct, that Vauvenargues shines. No century has ever excelled the 18th in moral theory, whatever may have been its deserts in respect of moral practice, and no 18th century moralist has excelled Vauvenargues. He is not an exact psychologist, much less a rigorous metaphysician. He has no worked-out or workable theory of moral obligation or of the moral sense. His terminology is merely popular and loose, and he hardly attempts the co-ordination of his ideas into any system. His real strength is in a department which the French have always cultivated with greater success than any other modern people—the expression in more or less epigrammatic language of the results of acute observation of human conduct and motives. The chief distinction between Vauvenargues and his great predecessor La Rochefoucauld is that Vauvenargues, unlike La Rochefoucauld, thinks nobly of man, and is altogether inclined rather to the Stoic than to the Epicurean theory. He has indeed been called a modern Stoic, and, allowing for the vagueness of all such phrases, there is much to be said for the description.

An edition of the *Works* of Vauvenargues, slightly enlarged, appeared in the year of his death, and in part or in whole has been frequently reprinted, all editions, however, being superseded by that of M. Gilbert (2 vols., Paris, 1857), which contains the previously unpublished correspondences above referred to and all other attainable matter, including some *Dialogues of the Dead*, some "characters" in imitation of Theophrastus and La Bruyère, and numerous short pieces of criticism and moralizing. Vauvenargues has been frequently written about, the comments best worth reading, besides those contained in Gilbert's edition, being four essays by Sainte-Beuve in *Causeries du Lundi*, vols iii. and xiv.

VECELLIO. See TITIAN.

VEDANTA. The Vedānta is the first and most impressive structure of Indian philosophy, the creed of intellectual Hindus, and the basis of the popular Hindu religions. Its earliest germs lie in the Mantra portion of the Veda. The Nāsadīyasūkta (*Ṛigveda*, x. 129) propounds the genesis of the world from an inscrutable principle, darkness, neither existent nor non-existent, and from "one that breathed without afflation, other than which there was nothing, beyond it nothing." The genesis of things from a universal soul is taught in the Purushasūkta (*Ṛigveda*, x. 90). The unreality of the internal and external orders of things, and the sole reality of a supreme spirit, or impersonal self, are set forth in the Upanishads or later portions of the Veda. The teaching of these Upanishads explicated and systematized, with little or no addition, constitutes the Vedānta. It has innumerable expositors among the Indian schoolmen, of whom the most illustrious is Śaṅkarāchārya (see SANSKRIT LITERATURE, vol. xxi. p. 300–4) a philosopher of Kerala or Malabar, who lived it is supposed, between 650 and 740.

The term "vedānta," end of the Veda, is a synonym of "upanishad." Upanishad is said by the Indian scholiasts to denote, in the first place, the knowledge of the impersonal self, the science of absolute being, *paramātmajñānā*, *brahmavidyā*, in the second place, any treatise imparting that knowledge. The doctrines of the Upanishads constitute the *jñānakāṇḍa*, or gnostic portion of the Veda, as distinguished from the *karmakāṇḍa*, or ritual portion, comprised in the Saṃhitās and Brāhmaṇas. They constitute also the *parāvidyā*, or superior science, dealing with cessation from volition and action, and leading to extrication from metempsychosis, as distinguished from the *aparāvidyā*, or inferior science, of the Saṃhitās, Brāhmaṇas and Vedāṅgas, which deals with action, and prolongs metempsychosis, leading only to higher embodiments in this world or in the paradises of the deities. The Vedānta philosophy is also called Aupanishadī Mīmāṇsā, Brāhmī Mīmāṇsā, Śārīrakī Mīmānsā. The Sūtras or mnemonic formulas in which the system is developed are the Vedāntasūtra, Brahmasūtra and Śārīrakasūtra. They are ascribed to Vyāsa or Bādarāyaṇa. The system is further styled the Uttaramīmānsā, as an investigation of the later portion of the Veda, as distinguished from the Pūrvamīmāṇsā of Jaimini, which is an investigation of the earlier part of the Veda. The purport of the Pūrvamīmāṇsā is *dharmajijñāsā*, inquiry into sacred prescription; the purport of the Uttaramīmàṅas, or Vedānta, is *brahmajijñāsā*, inquiry into the real nature of the soul.

There is, according to the Vedānta, but one substance or reality, ingenerable, immutable, incorruptible, eternal, and this is the supreme spirit, the impersonal self, the spiritual absolute, *ātman, paramātman brahman*. The series of bodies and of environments through which the soul appears to pass in its μετενσωμάτωσις are illusive, unreal, the figments of a fictitious illusion, *māyā*, *prakriti*, *avyakta*, *avyākṛita*. The individual soul *jīvātman*, *vijñānātman*, is personal only in fictitious semblance, only so long as it is implicated in the series of transmigratory states, and is in truth impersonal, one with the undifferenced self or Brahman. Its apparent and fictitious individuality, and its apparent action and suffering, are the individuality, the action, and the suffering of its illusory adjuncts, the organism and the faculties. The unity of all souls in the one soul is the highest truth, or, properly speaking, the only truth. On reaching and realizing this truth the individual soul returns to its isolation or state of pure indetermination. The duality of experience is fictitious and is surmounted by the true intuition, *samyagjñāna*. On the side of this intuition there abides only "the existent, the intelligence, the beatitude."

Indian philosophy, and in particular its earliest form, the philosophy of the Upanishads, or Vedānta, is governed throughout by two needs. First, there is the need to give consistency and coherence to existing imagery, physical and hyperphysical, to work out a conception of the totality of things. Secondly, there is the need to put a stop to the miseries of metempsychosis. The idea of transmigration, foreign to the Indo-Aryans of the Vedic hymns, appears to have been taken up by their successors from the lower races with which they intermingled, while retaining their supremacy among them. The Indo-Aryans of the Vedic hymns found life pleasurable and exciting. They prayed to the gods for their hundred years of it, and for an afterlife with the whole body. This view of life was replaced by one of horror and aversion, pervading everything Indian with its gloom,—the expectation of care, bereavement, sickness, pain, and death, in body after body, and through æon after æon.

The effort to work out a coherent and complete idea by means of some principle of unity appears in the following passages:

In the Muṇḍaka Upanishad: "Śaunaka, the householder, approached Aṅgiras and said, 'Holy sir, by knowing what may all this universe be known?' Aṅgiras replied, 'Two sciences are to be known which they that transmit the Veda propound, a superior and an inferior science. Of these the inferior is the *Ṛigveda*, etc. The superior is that by which that undecaying being is attained. That which none can see, none can handle, which is without kindred, without color, which has neither eyes nor ears, neither hands nor feet, which is imperishable, infinitely diversified, everywhere present, wholly imperceptible—that is the immutable, that it is that sages behold as the source of all.'" In reference to this text the scholiast Ānandagiri says: "If we know the *principium*, the *upādāna*, of things, we shall know all things, inasmuch as all things have pre-existed in and are identical with their causes." Śaṅkarāchārya says: "In daily life things are known to ordinary people, if the unities are known under which those things are contained. For example, individual pieces of gold are known under the nature of gold. Thus the question of the text is, what is the one cause or emanatory principle of the diversity of the universe, which known everything else is known?"

In the Chhāndogya Upanishad: "His father said to him, 'Śvetaketu, thou art high-minded, wise in thy own conceit, and proud. Tell me, hast thou asked for that instruction by which the unheard is heard, the unthought thought, the unknown known?' He answered, 'How is that instruction given, sir?' His father said, 'Dear son, as by one lump of clay all that is made of clay becomes known, being a modification of speech only, a change, a name, and the clay being the only reality; as by one piece of iron all that is made of iron becomes known, being a modification of speech only, a change, a name, and the iron being the only reality; as by a pair of scissors all that is made of steel becomes known, being a modification of speech only, a change, a name, and the steel being the only reality:—such is the method of that instruction.' Śvetaketu said, 'Sir, doubtless my teacher knew not that, for, had he known it, how could he have failed to tell me of it? Do thou therefore tell me of it? His father said, 'Be it so, my dear son. Existent only, fair youth, was this in the beginning, one only, without duality. Some indeed have said, non-existent only was this in the beginning, one only without duality. From that non-existent the existent proceeded. But how could this be so? how could entity proceed out of non-entity?'"

In the Śvetāśvatara Upanishad: "Those that proclaim Brahman say, What is the *principium?* Is it the impersonal self? From what have we proceeded into life? into what do we return? By what are we upheld as we pass through pleasures and pains? Is time the *principium?* Is the inherent property of things their *principium?* Is chance? Are the elements? Or is the individual soul the origin of all things? Or is the sum of these the *principium?* Neither is any one of these, nor are all of these, the *principium*, for it is the impersonal self. It is not the individual self, for that is not independent, being subject to pleasures and to pains."

The most powerful incentive to speculation was the yearning to escape the miseries of transmigration. The soul has to pass through hunger and thirst, sorrow, bereavement, decrepitude, death, in body after body, through age after age. The individual soul has to look forward to continual suffering through a countless series of embodiments. The series is without beginning, and, until the individual learns his impersonal nature, without end. The series of transmigratory spheres is projected and retracted, projected and retracted, from before all time. Periods of evolution and of dissolution follow each other from and to eternity. Any intervals of pleasure in the series of states through which the soul passes are fugitive and unsatisfying. Even the pleasures of the paradises of the deities are tainted with the fear of their expiry, and with the inequalities amongst the participants. They also are part of the darkness in which everything appears to be involved.

The transmigratory series, or *saṁsāra*, is said to consist of agents, actions, and fruits of action. The fruits of action are the bodies and the environments allotted according to good or evil works. It is described as an unbroken succession of evils, birth, death, bereavement and other sorrows,—arising from transition from body to body. The individual soul floats down the stream, "like a gourd upon the waters," through embodiment after embodiment, "from a patch of grass to the first of the divinities," through forms, inorganic and organic, vegetable, animal, human, ultra-human, infernal, and celestial. Each later stage is determined by the good or evil actions of the individual in his earlier embodiments, by a blindly, a fatally operating law of retribution, *adṛishṭa*. It is in conformity to this principle that the *opifex ædificatorque mundi deus*, the Demiurgus, Iśvara, puts together and rules the transmigratory series through the successive æons. It is this principle that clears the Demiurgus of the charge of cruelty and injustice on account of the miseries and inequalities of life. In all that it does and suffers the soul is reaping the fruits of its own actions. Its actions proceed from preferences and aversions, its preferences and aversions proceed from illusion, from its identifying itself with its *per se* unconscious senses, faculties, and organism. Merit, no less than demerit, prolongs the series, and must be shunned as sin by the aspirant to extrication.

The world, then, was pictured by the Indian sages as a series, beginningless and endless, of bodies and environments, through which personal souls—that is, the one soul illusively viewing itself as many—pass. They pass through it for the fruition of their works, *bhoga*. The material of which it is built up at each period of evolution is the cosmical illusion, *ajṇāna, avidyā, māyā, prakṛiti*. This is the principle by which soul mistakes itself for not-self, identifies itself with fictitious adjuncts, *upādhi*, with the organs, the faculties, the organism. It is this illusion that gives rise to the unreal world of duality, generable, mutable, corruptible, *avidyāparikalpitaṃ dvaitam*. It is illusion that projects the manifold of experience, *nānātvapratyupasthāpikā māyā*. As the flow of transmigratory experiences is a succession of pleasures, pains, and neutral states, the world-projecting illusion is defined to be pleasure, pain, and indolence in equilibrium, *guṇatrayasāmya*. Pleasure, pain, indifference, are the three *primordia rerum*, the factors of experience, the three strands of the rope that holds the soul in bondage. The world-projecting illusion is further spoken of as the power of the Demiurgus, his all-creative power, "the power of the divine spirit latent in its constituent *primordia*." Thus Śaṅkarāchārya in his Bhāshya on the Vedāntasūtra says: "Name and form (*i.e.*, all that is heard and seen), the fictitious products of illusion, and the body of the omniscient Demiurgus,—name and form, inexplicable as entity and as nonentity, the germs of the transmigratory series,—are called the illusion, the power, the productiveness (*prakṛiti*) of the Demiurgus." This illusion is "neither existent nor non-existent, nor both in one, neither to be explained as entity or as nonentity, fictitiously proceeding from and to all eternity." It is the illusory adjunct, *upādhi*, of Brahman. The internal and the external order of things are illusorily superposed (*adhyasta, adhyāropita*) upon the one and only real, the impersonal self, by an illusion that has imagined itself from all eternity.

To illustrate this in the figures of the Vedānta: "As a spider extends and retracts his threads, as plants grow up upon the earth, as the hairs of the head and body spring from the living man, so the world arises from the imperishable." "As from the blazing fire its kindred sparks proceed in thousands, so the diverse creatures proceed from that imperishable principle and into it return." All that presents itself to the soul in life after life, in sphere after sphere, lies in fictitious semblance above the real, like the blueness seen in the sky, though in the sky it has no existence; like the waters of a mirage; like the bubbles on the surface of a river; like the airy fabric of a day-dream; like the visions of a dream; like the silver seen, or seeming to be seen, on the shell of the pearl-oyster; like the snake seen by the belated traveller in a piece of rope; like the gloom that surrounds the owl amidst the noontide glare. The soul is confined to the body as within a prison. Its doings and sufferings are as unreal as the apparent motion of the trees upon the bank to one sailing down the river. The experience of life after life is the phantasmagory of a waking dream. The unreality, the fictitious nature, of the things of experience is implied everywhere in the Upanishads, and explicated with a profusion of imagery, by the Indian schoolmen.

The contents of this transmigratory series are supplied from the popular religion, the earlier imagery being built up into the new conception. A place is found in it for the deities and their paradises; only these deities and their paradises, up to the Demiurgus himself, the Īśvara, and the *brahmaloka*, the sphere of Brahmā, are *per se* fictitious, unreal, illusory. A sojourn in these paradises is promised to the religionist; assimilation to these deities is promised to those that worship them with knowledge as well as with rites. Every man, the Indian schoolmen say, shall be assimilated to the deity he worships. The highest reward of obedience to sacred prescription and of worship of the deities is continuance in the *brahmaloka* till the end of an æon, "relative immortality," *āpekshikaṃ nityatvam*. The only real immortality is extrication from metempsychosis, reunion with the impersonal self, to be reached not by works but by knowledge. They that delight in works, in rites, and the spheres won by works, wander in darkness, are like the blind led by the blind. Works and worship are, however, necessary to purify the intellect of the aspirant to extrication. The process of purification may go on through several successive lines. Good works performed without a view to recompense, and as an offering to the Demiurgus, produce that purity of the internal faculties which is requisite to the knowledge that terminates in liberation from metempsychosis. They are thus instrumental to emancipation. Good works are necessary, says Śaṅkarāchārya, to the rise of the spiritual intuition; they are unnecessary when it has once arisen. The qualified aspirant to liberation, the *adhikārin*, must renounce all works, the good as well as the evil, for they serve only to prolong the series of his embodiments. It is thus that the popular religion is taken up and fitted into the Vedānta philosophy. *Karmavidyā* is preliminary to *brahmavidyā*.

Māyā, the inexplicable illusion, self-imagined, has been the unreal adjunct, *upādhi*, illusorily overspread upon Brahman from all eternity. Brahman in its first connection with ignorance or illusion is the Demiurgus, Īśvara, Parameśvara, the constructive and superintending deity of the Vedāntins. Before describing the process of things at a period of evolution, the conception of Brahman, the impersonal self, must be unfolded in the terms of the Vedānta.

Brahman is the one and real that underlies the many and apparent. It is ingenerable, immutable, incorruptible. It is the ultimate residuum of abstraction, to be spoken of only under negative predicates, *sarvanishedhāvadhi*. It transcends duality, the world of subject and object, *jñātṛijñeyabhāvātirikta*. It is one only without internal and external differences. "There is nothing before it, nor after it, nor within it, nor without it." It is everlasting, objectless cognition, *nityaṃ nirvishayaṃ jñānam*. "Of the sight of the seer there is no intermission, for it is imperishable." It is no object of the understanding, and it cannot be expounded in language. "From it words turn back, with the thinking faculty, not reaching it." And this Brahman, this impersonal self, is I, *ahram bahmāsmi*.

The impersonal self, Brahman, is "existent, intelligence, beatitude," *sachchidānanda:* existent, as imparting existence and manifestations to everything that is known and seems to be, *sattāsphūrtipradatayā;* intelligence, as being self-luminous, as giving light to all things, making to appear all things that do appear, *svaprakāśaka, sarvāvabhāsaka;* beatitude, as exempt from all the miseries of metempsychosis, from evil, pain, and sorrow, a beatitude in which there is no distinction between the bliss and the blissful subject, *ānanda* and *ānandin*, a beatitude like the repose of dreamless sleep. It is "ever pure, intelligent, and free," *nityaśuddhabuddhamukta:* pure, as free from desire and aversion, and passionless, and as unaffected by illusory limitations, *nirupādhika;* intelligent, as irradiating all things, illuminating the otherwise dark or unconscious modifications of the sensories and intellects of personal spirits, and as illuminating the objects of those modifications; free, as unaffected by the experiences of those spirits, exempt from implication in the unreal. It is unmodifiable, and therefore neither knows, nor acts, nor suffers. All cognition, action, and passion belong to the unreal world of duality, and are the modifications of the sensory and intellect of personal souls. These modifications would be dark, that is unconscious, but for the light of the underlying real self, in which they shine forth. In the absence of that real self the whole transmigratory order would be involved in blindness, *tadabhāve jagadāndhyam prasajyta*. It is the witness,—that is, the inner light—of the cognitions of the intellects of all personal souls, *sarvabuddhipratyayasākshin*.

It is "the light of lights beyond the darkness." "To it the sun gives no light, nor the moon and the stars, nor the lightning,—how then this fire? That, as it shines, all the world shines after. By the light of that all this world shines forth."

Brahman is said to abide especially within the heart, for it is there that the internal faculties are lodged, and it is by the light of Brahman that they are illumined. It is "the one spirit internal to all sentiencies," *ekaḥ sarvabhūtāntarātma*. It is present to them all, as the one sun is mirrored upon many watery surfaces, as the ether one and indivisible in many water-jars. The personal self, the *jīvātmān*, is said to be resolved into the impersonal Brahman in three states,—in dreamless sleep, in a period of dissolution between two æons, and in emancipation. Dreamless sleep is called a "daily dissolution," *dainandinaḥ pralayaḥ*.

To Brahman alone belongs existence in the strict sense of the term, *pāramārthikī sattā*. It is; everything else appears to be. The things of daily life have a conventional existence, sufficient for acting upon, insufficient to the reason, *vyāvahārikī sattā*. The silver seen upon the shell, the snake seen in the piece of rope, have an apparent existence, *prātibhāsikī saitā*. For the sage conventional existence is only apparent existence. At the foot of the scale of being stand things impossible or absurd, *tuchcha*, as the flowers of the sky, the horns of the hare.

Brahman is both the real and the operative cause of the world, the *upādāna* and the *nimitta*. It is the real cause, inasmuch as the transmigratory series fictitiously overlies it. "Over this the sky, the earth, the welkin, are woven." "Illusion," says Śankarāchārya, "the aggregate of the powers of all causes and effects, reposes upon Brahman, woven across and across it, as the potentiality of the banyan-tree reposes in the seed of the tree." "A fictitious object," says Ānandagiri, "such as the snake seen in a piece of rope, has a relatively real substratum in the piece of rope; the transmigratory series, unreal because phenomenal, has a real substance beneath it." Brahman is the operative cause of the world, inasmuch as the world-projecting illusion, inert of itself, becomes active by proximity to Brahman, as iron is set in motion by the loadstone, the iron being inert of itself, and the loadstone unmoved and unchanged.

A process of evolution is called a "differentiation under name and form," *nāmarūpavyākaraṇa*. Processes of evolution and of dissolution follow one another from eternity to eternity. Embodiments have proceeded from works, and works from embodiments, in a series without beginning, as plants proceed from seeds and seeds from plants. The series must proceed for each individual until he learns his real nature, and becomes re-immersed in the fontal unity. The one, the ultimate spiritual reality, is knowledge. The many is ignorance, the semblance of knowledge, fictitious cognition, illusion. Ignorance is not mere privation of knowledge: it has a kind of being; it is a false identification of self with not-self, *bhāvarūpam ajñānam, viparītajnanam ajnanam*.

A process of evolution is as follows:

(1) Brahman overspread with illusion manifests itself as Iśvara, the Demiurgus. The illusion of Īśvara is one with the illusion of each and every sentiency, and of all sentiencies or *jīvas*. It is at once one and many. As one it is the causal body of the Demiurgus; as many it is the beatific *involucra* of sentiencies, their *ānandamayakosha*. The Demiurgus and the sentiencies are one. Their state is a state of dreamless sleep, a state of beatitude. Īśvara, the Demiurgus, is the first figment of the cosmical illusion. The Demiurgus allots to transmigrating spirits their several bodies and spheres of fruitions, in accordance with the law of retribution, and retracts them into himself at the dissolution of the æon. Knowledge of the real nature of his soul frees a man from all fear of Īśvara.

(2) Brahman overspread with illusion next manifests itself as Hirañyagarbha. As one it manifests itself as Hirañyagarbha; as many it is the sentiencies or *jīvas* in the state of dreaming sleep, *taijasa*. Illusion has two powers,—that with which it envelops the soul, hiding from it its proper nature, the *āvarañaśakti*, and that with which it projects the seeming bodies and their seeming spheres, the *vikshepasakti*. The elements, as yet imperceptible, come into being. Out of these the tenuous *involucra*, the ventures of the spirit in its passage from body to body, are evolved. Out of the imperceptible elements the perceptible are afterwards evolved. The soul clothed upon with a tenuous *involucrum*, and passing with it from body to body, from sphere to sphere, is the individual soul, the *jīvātman*. Hiranyagarbha is spirit identifying itself with the as yet imperceptible elements, and with the tenuous *involucra*. It passes through them as a thread passes through the beads of a necklace, and is called the thread-soul, Sūtrātman.

(3) Brahman overspread with illusion finally manifests itself as Vaiśvānara or Virāṭ. As one it is Vaiśvānara, as many it is the sentiencies or *jīvas* in the waking states *viśva*. Vaiśvānara is the Purusha of the Purushasūkta: "A thousand heads has Purusha, a thousand eyes, a thousand feet." Purusha is Brahman, illusorily identifying itself with the perceptible elements, and with the bodies of all transmigrating spirits. Every sentiency, every man, in the waking state, is Brahman illusively identified with this or that visible and tangible organism. The perceptible are evolved out of the imperceptible elements by the process of quintuplication, *pañchīkaraṇa*. Each of the latter of the five elements has the property of the earlier elements in addition to its own. Ether has the property of sound; air the properties of sound and tangibility; fire the properties of sound, tangibility, and color; water the properties of sound, tangibility, color, and taste; earth the properties of sound, tangibility, color taste, and smell. Of these elements the bodies of transmigrating spirits, and their several spheres of fruition, are composed.

Such is the order of evolution. An evolution is conceived by the Vedāntins as an instantaneous process, rapid as a flash of light.

There are, then, three orders of intelligence in three states of experience—(1) the Demiurgus, and the individual soul in the state of dreamless sleep; (2) Hiraṇyagarbha, and the individual soul in the state of dreaming sleep; (3) Vaiśvānara, and the individual soul in the waking state.

There are for these three orders of bodies—(1) the causal body of the Demiurgus, and the wrapper of bliss; (2) the tenuous *involucra* of transmigrating spirits—(these are made up of three wrappers, laid above the wrapper of bliss, viz., the cognitional wrapper, or the intellect and the organs of sense; the sensorial wrapper, or the common sensory and the organs of action; the respiratory wrapper, or the five vital airs, and the organs of action);—(3) the gross *involucra*, the visible and tangible bodies of transmigrating spirits, or nutrimentitious wrapper. Invested in these five successive wrappers one above the other, the impersonal self manifests itself in the shape of innumerable sentiencies, as beast, as man, as god. It is present in all, as the one sun reflects itself upon many pools, as the one ether spreads itself through many water-jars. It is at the same time, apart from these illusory adjuncts, untouched with mundane sorrows, as the sun looks down upon the impurities of the earth without defilement.

Out of these successive *involucra* the individual soul, to extricate itself from metempsychosis, has to extract itself "like the pith out of a reed." It extracts itself by returning to its proper nature. And to learn and recover his proper nature, his real self, a man must purify his intellect, perhaps through several lives, and must put himself under a spiritual preceptor to whom the Vedantic doctrine has descended through an unbroken line of authorized exponents. Brahman is to be known by traditional exponents, not by the mere exercise of the intellect. "Not he that has not ceased from evil, not he that rests not from sensations, not he that is not concentrated, not he whose faculties are not quiescent, can reach that self by the intuition." "This spiritual reality is not to be reached by learning, by memory, by much spiritual study. But if he choose this reality it may be reached by him; to him the self unfolds its own essence."

The aspirant to extrication, the *mumukshu*, must renounce everything in this and in future spheres of fruition. He must become a *sannyāsin*. In the words of the Bṛihadāraṇyaka Upanishad: "They that know the breath of the breath, the eye of the eye, the ear of the ear, the thought of the thought, they have seen this fontal spirit, primeval, existing from before all time. It is to be seen with the intellect only. In it there is nought that is manifold. From death to death he goes that looks on this as manifold. It is to be seen in one way only. It is unthinkable, imperishable, unsullied, beyond illusion. Unborn, infinite, imperishable, is Self. Let the patient Brāhman know that and learn wisdom. Let him not learn many words, for that is a weariness of the voice. This indeed is the great Unborn Self. This it is that holy mendicants yearn after in setting out upon their wandering life. Yearning after this it was that the ancient sages desired no offspring, saying, "What have we to do with children, we to whom this spiritual reality belongs in the real sphere? They arose, and forsook the desire of children, of wealth, and of worldly existence, and set out as holy mendicants.'" The tardy aspirant, *mandādhikārin*, who seeks for gradual emancipation, *kramamukṭi*, is enjoined to mutter and to ponder incessantly upon the mystic syllable Om. This is said to be the nearest image of Brahman, to be identical with all words, and with all things.

"They make mistake who leave me out,
Me, when they fly, I am the wings;
I am the doubter and the doubt,
And I the hymn the Brahman sings."

The spiritual preceptor proceeds by the way of "illusory superposition, and the sublation of that superposition," *adhyāropāpavādanyāyena*. Illusory superposition is the viewing of the unreal, the fictitious series of souls and their environments, upon the one and only real. The sublation of this superposition is the position of the impersonal self, Brahman, as the sole reality, and the recognition of the falsity of the fictitious illusion and of all its figments. The doctrine of sublation is expounded as follows in Nṛisiṇhasarasvatī's Subodhinī: "Sublation is the annulment of the series proceeding from illusion. The states in this series are illusory emanations, *vivartta*, of Brahman, and to annul them is to abide as pure, undifferenced spirit. The apparent snake of the familiar example, seen by the belated wayfarer, illusorily proceeds from, or is fictitiously produced upon, the piece of rope, without any change of nature taking place in the rope itself. It is sublated when the piece of rope resumes its proper shape. A thing may retain its own nature, and become otherwise than it was, in two manners, viz., by modification, *pariṇāma*, and by illusory emanation, *vivartta*. Modification is when a thing really quits its proper form and takes another shape. Milk, for example, quits its proper form to take the form of curds and whey. Illusory emanation is where a thing, without quitting its proper form, takes another and a fictitious shape. The piece of rope takes the fictitious appearance of a snake without quitting its proper form; it remains a piece of rope. The transmigratory series is not allowed in the Vedānta to be a modification of Brahman. Brahman, if modified as the milk is modified, would be mutable, and therefore perishable. The doctrine of illusory emanation is not exposed to this difficulty. The series superposed on Brahman being fictitious, Brahman remains unchanged. A fictitious thing, then, is said to be sublated when only the real thing abides upon which it was imposed. The transmigratory series is sublated when only the pure intelligence remains upon which it was fictitiously outspread."

By continuous contemplation the aspirant refunds each entity into the entity from which it emanated, till he passes beyond illusion to the fontal unity of undifferenced spiritual existence. He follows the order of dissolution, the inverse of the order of evolution, till he arrives at Brahman. He thus realizes the import of the great text, the *mahāvākya*, "that art thou," *tat tvam asi* (Chhāndogya Upanishad, sixth Prapāṭhaka). Particular souls are one with the universal soul, the Demiurgus, and the universal soul is one with Brahman. This knowledge is the last and highest of cognitions, the final modification of the aspirant's intellect as it melts away into the fontal unity. This is the *phalitam brahma*, "the resultant impersonal self." The *phalitam brahma* is a modification of the aspirant's sensorium, his *antaḥkaraṇa*, and passes away, that the impersonal self, the supreme spirit, may alone remain. He to whose inner faculties this vision is present has the spiritual intuition, *samyagdarśana*. He is extricated but alive, *jīvanmukta*, and remains in the body till those merits are exhausted which have led to his present life. Disengaged from metempsychosis, and still in the body, the perfected sage is said to be untouched by merit and demerit, unsoiled by sin, uninjured by anything he does or leaves undone. No evil, the scholiasts say, arises from this freedom, as the purificatory virtues of the aspirant cling to the accomplished seer,—his humility, his sincerity, his tenderness to all, remaining upon him like ornaments even after the rise of the spiritual intuition. Finally his body falls away, and his spirit is freed forever. It abides in itself. It is undifferenced existence, undifferenced intelligence, undifferenced beatitude. This is the consummation of *brahmavidyā*.

The soul has found itself, has loosed itself, not that in verity it was ever lost or bound. From the highest point of view bondage and liberation, implication and extrication, are unreal. The Vedāntins compare the individual spirit seeking to regain its impersonal nature to one searching for that which he unwittingly carries about with him, to a man trembling at his own shadow. The soul of the finished sage knows itself and therefore is itself. In the words of the Muṇḍaka Upanishad: "Burst are his heart's ties, broken his doubts, his merits spent, when he has seen the principle supreme at once and not supreme. In the golden, perfect *involucrum* is the unsullied Self, without parts, luminous, which they know that know the soul." "As all rivers flowing onwards disappear in the sea, quitting name and form, so the sage extricated from name and form enters into the self-luminous spirit beyond the last of things, beyond illusion." In the words of the Brihadāraṇyaka: "He that knows it is no longer sullied by evil deeds. Repressing his senses, quiescent, free from all desires, ready to suffer all things, his thoughts fixed, he sees within himself the Self, the universal soul. Imperfection reaches him no more; he passes beyond imperfection. He burns up all his imperfection. He that knows Brahman becomes free from imperfection, free from uncertainty, insphered in Brahman. This same great, unborn Self is undecaying, undying, imperishable, beyond all fear. Brahman is beyond all fear. He that knows this becomes the spiritual reality beyond all fear." (A. E. G.)

VEDAS. See BRAHMANISM and SANSKRIT LITERATURE.

VEDDAHS, or WEDDAHS, that is, "Hunters," a primitive people of Ceylon, probably representing the Yakkos of Sanskrit writers, who appear to have been the true aborigines and the sole inhabitants of the island prior to the Hindu conquest. During the Dutch occupation (1644–1796) they were met in scattered groups as far north as Jaffna, but are now confined to the southeastern district, about the wooded Bintenne, Badulla, and Nilgala Hills, and thence to the coast near Batticaloa. They constitute three distinct social groups—the *coast people*, who are settled and partly civilized, freely intermingling with their Singhalese neighbors; the *wild* or *rock people*, who keep entirely aloof, living exclusively on the produce of the chase; and the *village people*, semi-nomad agriculturists, intermediate in every respect between the other two. The Veddahs are thus in a state of transition from the lowest to a relatively high degree of culture; and their physical appearance gives evidence of their intermediate position between the aboriginal and the intruding races of Ceylon. Virchow[1] finds (1) that the Veddahs and Singhalese have much in common, which is probably due to the intermingling of the aborigines with the Hindu immigrants, as is also suggested by historic and anthropological considerations; (2) that both differ very decidedly from the Tamils of north Ceylon and south India; (3) that the Veddahs show certain analogies with the small dark pre-Dravidian element in this region, which De Quatrefages calls "Negrito," and which Huxley groups with his "Australoid" division of mankind. The true Veddahs of Bintenne are almost a dwarfish race, averaging about 5 feet (men, 5 feet 2 inches; women, 4 feet 10 inches), with correspondingly low cranial capacity, narrow high skull like the Papuan (index 70), mesognathous jaw, slightly prominent cheek-bones, straight, but shaggy rather than lank, black hair, and features altogether more Hindu than Negroid, although of somewhat darker complexion than the ordinary olive-brown Singhalese. They wander about in small family groups, which have not reached the tribal state, being absolutely destitute of any political or communal organization whatsoever. Their dwellings are the caves of the rocks or the forest trees; they clothe themselves with foliage; and they devour uncooked vermin, reptiles, and whatever other quarry they are able to capture with their rude weapons. It is stated that they can neither count, mark the succession of time, nor distinguish colors; but what is more certain is that they never laugh, in this respect differing from nearly all other races. They also appear to be the only savage people who speak an Aryan language, for their present speech at least seems to be a degraded form of Singhalese, consisting mainly of Sanskrit intermingled with Dravidian elements. This circumstance has given rise to the theory that the Veddahs are a degraded group of Hindu outcastes, whereas they call themselves the "sons of kings," and claim to belong to a superior caste, a claim which, strange to say, appears to be admitted by their neighbors. Their religion has been described as a kind of demon-worship, consisting of rude dances and shouts raised to scare away the evil spirits, whom they confound with their ancestors. But these "demons" and "spirits" are purely anthropomorphic beings; of a supernatural order as understood by more cultured peoples they have no idea. Owing to an increasingly low birth-rate, the Veddahs are disappearing as a distinct ethnical group; even including the Rhodiyas of the western uplands they numbered only 2284 in 1886 (Ferguson's *Directory*). But they should not be confounded with these Rhodiyas, who, although true outcastes, are nevertheless a much finer race, tall, well-proportioned, with regular features, and speak a language said to be radically distinct from all the Aryan and Dravidian dialects current in Ceylon. There is, however, in Travancore on the mainland, a low-caste "Veda" tribe, nearly black, with wavy or frizzly hair, and now speaking a Malayâlim (Dravidian) dialect (Jagor), who probably approach nearer than the insular Veddahs to the aboriginal pre-Dravidian "Negrito" element of southern India and Malaysia.

---

VEGA CARPIO, LOPE FELIX DE (1562–1635), Spanish dramatist and poet, was born on 25th November, 1562, at Madrid, in a house in the Platerias or jewellers' quarter adjoining the Puerta de Guadalajara. His father and mother, Felix de Vega and Francisca Hernandez, belonged to the lesser provincial nobility, and originally came from the valley of Carriedo in Asturias, where the hamlet of Vega still exists. How they came by the illustrious name of Carpio is not very clear; the family tradition which made them descendants of the famous Bernardo seems insufficiently supported. Lope himself frankly ridiculed the aristocratic pretensions of his parents; but this did not prevent him from invariably signing his comedies at full length as Lope de Vega Carpio. Lope began his studies in the imperial college, the principal establishment of the Jesuits in Madrid, where he was instructed in grammar and rhetoric. His precocity was extraordinary and his memory astounding. At five he read not only Spanish but Latin, and already showed such a passion for poetry that he would give up part of his meals to the older boys in exchange for their services in writing out verses to his dictation. It was not the way of the Jesuits to turn out pedants; educators of the nobility, their single aim was to make their pupils accomplished men of the world, and accordingly Lope learned with them, besides the ordinary book-lessons, the accomplishments of singing and dancing and fencing. On leaving college—where he had been guilty of an escapade of some sort along with one of his companions—he was placed by his parents, who were far from wealthy, in the service of Don Gerónimo Manrique, bishop of Avila. Such an arrangement did not at that time involve any sacrifice of dignity; it was almost the only resource open to a multitude of needy gentlemen, *hidalgos*, who, to avoid entering a trade, which would have compromised their position, found in the palaces of the higher aristocracy, first as pages and afterwards as secretaries, the wherewithal to *pasar la vida*, as the phrase ran. In the service of Don Gerónimo, Lope appears to have begun the composition of his earlier dramas. But after a while he quitted the bishop's service to enter the university of Alcalá, where for four years he devoted himself to what was then honored with the name of philosophy, crammed his brain with names and citations from ancient writers, and acquired the habit of disputing in accordance with the formulæ of the schools. It was then that he accumulated the materials for the pedantic dissertations with which the prefaces to his various works are encumbered, in which he so complacently displays everything that he has remembered of his university days. Leaving Alcalá with the degree of bachelor in arts, Lope became secretary to the duke of Alva. Some time afterward, about 1584, he married Isabel de Urbina, daughter of a herald-at-arms of Philip II. An incident such as he often afterwards reproduced in his plays soon arose to disturb the union. Some one who had spoken ill of Lope, and had in turn been severely lampooned by the poet, challenged him. In the encounter Lope wounded his opponent; but he was unable to put himself right with the law and was compelled to take to flight. Perhaps he may have had upon his conscience some other peccadilloes which prejudiced him in the eyes of his judges, as seems to be hinted in Montalban's words, "This vexatious affair, and certain other bad turns of fortune, . . . compelled him to leave his home, his country, and his wife." He retired to Valencia, where he met with an enthusiastic reception from a group of young poets, who were destined afterwards to range themselves under the banner of the creator of the new comedy. After the lapse of two years Lope returned to Madrid; but in 1588 his wife died after giving birth to a daughter, who did not long survive her mother. The death of his wife and daughter were doubtless what now led him to join the Invincible Armada, in which expedition he had one of his brothers shot dead by his side. Once more at Madrid, he again entered service, becoming secretary, first to the marquis of Malpica and afterwards to the duke of Lemos. Meanwhile he married a second wife, Juana de Guardio, a Madrileña, by whom he had two children (Carlos, who died in infancy, and Feliciana Felix); but she died, shortly after giving birth to the latter, in 1612. During this wife's lifetime the poet had by a mistress, Maria de Luxan, two other children,—Marcela del Carpio, who became a nun, and Lope Felix del Carpio y Luxan, who chose the profession of arms and perished at sea at the age of fifteen. Widowed a second time, Lope, like many other men of letters of the period, sought a refuge in the church. After a period of initiation and after having been for some time affiliated to a tertiary order, he took priest's orders. At this juncture, that is to say, about 1614, he was in the very zenith of his glory. A veritable dictator and pope in the Spanish world of letters, he wielded over all the authors of his nation a sort of magisterial power similar to that which was exercised in France at a later period by Voltaire. At this distance of time we fail to see in Lope anything more than a great dramatic poet, the founder of the Spanish theatre; but to his contemporaries he was a great deal more. His epics, his pastorals, his odes, his sonnets, buried though they now are in oblivion, all placed him in the front rank of authorship. Such was his prestige that he dealt with his noble patrons almost on a footing of equality. The duke of Sesa in particular, his last Mæcenas, was also his personal friend, and the tone of the letters addressed to him by the poet is that of a frank familiarity, modified only by some forms of deference,—a fact sufficiently striking to be worthy of notice at a time when talent, however great, in no way diminished differences of rank, and when the man of letters under the protection of a patron was neither more nor less than a kind of domestic in the house of a *grand seigneur*. Lope's fame, too, had travelled abroad: foreigners of distinction passing through Madrid made a point of visiting him; papal legates brought him the compliments of their master; in 1627 Urban VIII., a Barberini, sent him the diploma of doctor of theology in the Collegium Sapientiæ and the cross of the order of St. John of Jerusalem (whence the poet's titles of *Doctor* and *Frey*). Since Lope's correspondence with the duke of Sesa has made us acquainted with the closing period of his life, we may well ask whether his retirement within the church was the result of any genuine vocation, and up to what point his devotion was sincere. It is difficult to avoid inquiring whether it may not have been due to a mere selfish desire for tranquillity, a desire to protect himself against any further reverse of fortune. This feeling may very well have had something to do with his decision; still it would be unjust to regard Lope as nothing better than a mere hypocrite. Certainly he was far from being an ideal priest; we now know something of the nature of the services which he often rendered to the duke of Sesa, and we know how lightly he held one of his most sacred vows, maintaining for a long period illicit relations with Marta de Nevares Santoyo, a married woman, by whom he even had a daughter, who was baptized very publicly at San Sebastian in Madrid (26th August, 1617), the son of the duke of Sesa acting as godfather. But, on the other hand, we must not forget his penitence, frequently expressed in touching terms, the sincerity of which ought to be above suspicion: "Mal haya amor que se quiere oponer al cielo!" He has a claim also to our pity for having been at an advanced age the victim of foolish passion which his extreme mobility of character and his utter want of balance made him unable to resist: "Yo nací en dos extremos que son amar y aborrecer; no he tenido medio jamás." His last years were years of severe penance: Montalban tells us that every Friday the poet scourged himself so severely that the walls of his room were sprinkled with his blood. His death, on 27th August, 1635, was followed by national mourning. The duke of Sesa, his executor, was chief mourner; the nobility and the church were represented by high dignitaries; the populace crowded the streets. After the funeral came a multitude of funeral orations and of panegyrics in prose and verse. Montalban has collected into a volume the tributes of posthumous admiration thus paid by Spanish authors; another collection was printed in Italy under the auspices of Marini.

In the intercourse of everyday life, in his relations with his contemporaries, Lope was affable and kindly. He sometimes defended himself when attacked, especially on the subject of his dramatic writings, but always in measured terms and without any pretence that his high position exempted him from criticism by his less successful rivals. Some severe and unjust criticisms on other writers, notably on Cervantes, are quoted against him; but it is only fair to remember that they occur in letters to his intimates and that it is not necessary to regard them as deliberate. It would be just as fair to set him down as an enemy of the secular clergy because in writing to the duke of Sesa he on one occasion expressed himself thus freely about the monks: "Los frailes son los hombres mas discretos del mundo: no van a la guerra, ni pagan millones, gozan lo mejor, y danles dineros, . . . ellos hacen hijos y otros los crian, perdone lo descalzo." It would indeed be more just to reproach him with his universal and uniform indulgence, which he extends to all, great and small, good and bad, and with his mania for praising in hyperbolical and extravagant terms. He loved all the arts, particularly painting; his little house in the Calle de Francos was full of pictures. He himself writes to a friend in 1619: "With some garden flowers, half-a-dozen pictures, and a few books, I live without envy, without desire, without fear, and without hope" (dedication of *El Alcalde Mayor*). But his most marked taste was for flowers. He had a small garden, which he himself tended with jealous care; he sought out rare species and tried to acclimatize in Spain varieties of plants sent by his friends from abroad. In particular he was a tulip-fancier; hence his dedication of *Lucinda Perseguida* to Manuel Sueiro, a Spaniard resident in Flanders who had supplied him with fine specimens. Tending this garden became the great occupation of his old age; he watered it with his own hands, and according to Montalban, the chill which led to his death was caught while he was thus engaged.

One can easily detect in his writings the traces of this taste. It is not that he had in a higher degree than his contemporaries the feeling for nature, but the form, the color, the perfume of flowers largely supply him with his figures and metaphors—his flowers of rhetoric, in short. It is to be regretted that this delicate taste of his, a taste very rare in Spain, where flowers and trees have never been greatly cared for, should have contributed rather to augment than to lessen the elaborateness, pomposity, and affectation of his style. But these faults were shared by all the writers of that age. In his comedies, for example, where he does not pique himself on a fine style and does not attempt to take the Latins or the Italians for his models, his language is, if not nervous and self-restrained, at least limpid and flowing, in this respect contrasting very favorably with the florid and labored style of his epics and prose pastorals. Viewed broadly, and leaving out of account certain theories which in the long run greatly influenced his manner of writing, Lope belonged in literature to what may be called the school of good sense; he made it his boast that he was a Spaniard *pur sang*, and steadfastly maintained that a writer's business is to write so as to make himself understood. When brought face to face with the coterie of the *précieux* and *quintessenciés*, the "cultos," and "críticos," and "conceptistas," Lope takes the position of a defender of the language of ordinary life, the good old Castilian tongue. In the dispute which arose between the partisans of the two schools of "cultos" or "culteranos" and "llanos," the dramatist ranged himself on the side of the latter. In the matter of versification he refuses to admit that the long Italian verse has the advantage of the Castilian octosyllabic: "No pienso que el verso largo Italiano haga ventaja al nuestro, que si en España lo dizen es porque, no sabiendo hazer el suyo, se passan al estrangero como mas largo y licencioso. . . . Qué cosa iguala á una redondilla de Garci Sanchez ó Don Diego de Mendoza?" (Preface to *Isidro.*) Unfortunately the books that he read, his literary connections, his fear of being unfavorably judged by the Italians, all exercised an influence upon his naturally robust spirit, and, like so many others, he caught the prevalent contagion of mannerism and of empty and pompous phraseology. In his studies at the imperial college and at Alcalá Lope had never found his way up to the truest and highest sources of the beautiful; he had never attempted Greek, but had contented himself with Latin, which he chose to regard as the only ancient tongue which a man of letters needed to learn. To his natural son, Lope Felix del Carpio, when entering upon his Latin studies, he wrote, "So you have begun to grapple with the rudiments? It is one of the things which cannot possibly be avoided; but, for all that, if I could find some one to teach you your own language well, I should be quite satisfied, for I have seen too many of those who, having learned Latin, are ignorant of their native tongue and affect to despise everything written in the vulgar idiom. What presumption to forget that the Greeks did not write in Latin or the Latins in Greek! I confess I laugh whenever I see men giving themselves out for Latin poets who write in their own language like mere barbarians; and I conclude that they cannot possibly have been born poets, for the true poet (there is not more than one, they say, in a generation) writes in his own language, and it is therein that he shows his excellence,—witness Petrarch in Italy, Ronsard in France, and Garcilaso in Spain. Nevertheless I do not wish to discourage you from learning that queen of languages (Latin), the third in the world in point of antiquity. Try to know it as well as you can, my son, but by no means learn Greek, for I would not have you like those who strut and give themselves airs because they have acquired a smattering of it. Greek tends too much to vanity, and what is the use of learning a language which is known to so few?" After thus warning his son against the dangers of Greek, Lope adds other counsels which reveal to us his feelings towards his own bygone days. "Have but few books, and those chose with care; diligently observe the thoughts they contain, and do not let anything noteworthy pass without a mark on the margin. Should it be your misfortune to become a maker of verses (which God forbid!) try at least not to make that your chief occupation, nor let it divert you from more important matters, for therein you will spend your time to no profit. The less of verse you make the more you will be esteemed and appreciated. You need only take an example from me. Certainly you will never be able to render more services than I have done to so many patrons, and see to what my diligence has brought me,—to the smallest of houses, a narrow bed, a poor table, and a patch of garden, the flowers of which dispel my cares and supply me with ideas." Lope knew only Latin, but this he knew well. Yet, instead of filling himself with the spirit of antiquity, and purifying his taste by contact with its literary masters, he regarded their writings as nothing more than repertories of beautiful and out-of-the-way expressions. After the Latins Lope turned by preference to the Italians. Like every other Spanish man of letters of his time, he had been reared on Italian literature: he knew intimately the works of its great poets of the Renaissance, especially Ariosto and Tasso, as well as Sannazaro, the last-named of whom he imitated on several occasions; he kept a steady watch upon all that was published in Italy, cultivated carefully the connections he had established with Italian writers of repute, and was always flattered by the eulogies which reached him from that quarter. His principal friend and correspondent in Italy was the Neapolitan poet, G. B. Marini, one of the worst corrupters of

Italian literature (see vol. xiii. p. 521). He puts himself at Marini's feet, calls him *antistes Musarum* and *Italiæ decos*, sends him his portrait, and humbly begs his indulgence for a drama which he has been so bold as to dedicate to him (see dedication to *Virtud, Pobreza, y Muger*). Lope knew French also, and his works give evidence of an acquaintance with French poetry of the 16th and 17th centuries such as is rare in Spain; he occasionally quotes Ronsard and Malherbe, and shows solicitude as to French opinion about his dramatic writings. In a word his literary culture was chiefly Latin-Italian; and if he defends the tradition of the nation, and the pure simplicity of the old Castilian against "los de la nueva poesia," that is to say, the innovators of the school of Gongora, and against the jargon of the "cultos," still he does not wish to be taken for an uninformed person, for a mere casual litterateur devoid of classical training: he especially emphasizes the fact that he has passed through the university, and is continually accentuating the difference between the "ingenios científicos" (those who know Latin) and "legos ignorantes" (ignorant laymen). With what a sense of superiority, for example, does he mention that Cervantes was not to his mind sufficiently "científico" (preface to *Las Fortunas de Diana*), the fact being that Cervantes had been neither at Alcalá nor at Salamanca!

For a rapid survey of the works of Lope, it is convenient to begin with those which the Spaniards include under the name of *Obras Sueltas*, the title of the large collection of the poet's non-dramatic works (Madrid, 21 vols. 4to, 1776–79). We shall enumerate the most important of these, as far as possible in the order of publication. The *Arcadia* (1598), a pastoral romance, composed at the instance of the duke of Alva, and inspired by Sannazaro, Montemayor, and Cervantes, is one of the poet's feeblest and most wearisome productions. *Isidro* (1599), a narrative of the life of Isidore, patron of Madrid, is called a Castilian poem on account of the rhythm in which it is composed—*quintillas* of octosyllabic verse. The *Hermosura de Angélica* (1602), in three books, is a sort of continuation of the *Orlando Furioso*, in octaves after the fashion of the original poem. Similar in form is *La Dragontea*, a fantastic history of the last expedition and the death of Sir Francis Drake, who was such a terror to the fleets and the coast of Spain that his name had become a synonym for that of the evil one. Finally the *Rimas* are a miscellany of short pieces. In 1604 was published the *Peregrino en su Patria*, a romance in prose and verse, similar in kind to the *Æthiopica* of Heliodorus; it is a mediocre work, but of great bibliographical interest, on account of its authentic list of the comedies which Lope recognized as having been written by him up to that date, a list which he augmented by 114 new titles in the 1618 edition of the novel. The more Lope composed poetry the more he went to the Italian poets for inspiration, laboring to show that the mechanism of the Italian octave was as familiar to him as that of the national redondilla. Having imitated Ariosto, he proceeded to imitate Tasso; but his *Jerusalem Conquistada* (1609) has preserved nothing of the art shown in its model, and is a dull and insipid performance. Little need be said about the *Pastores de Belen* (1612), a sort of pious pastoral, dedicated to his son Carlos, which forms a pendant to his secular *Arcadia*, or about the incidental pieces which he published in connection with the solemnities of the beatification and canonization of St. Isidore in 1620 and 1622. And it is enough simply to mention *La Filomena* (1621), *La Circe* (1624), and other poems published about the same date, as also the four prose novels, *Las Fortunas de Diana*, *El Desdichado por la Honra*, *La Mas Prudente Venganza*, and *Guzman el Bravo*. The great success of the *Novelas Egemplares* of Cervantes (1613) had stimulated Lope, who wished to measure himself with the author of *Don Quixote* on the field of the novel; and, as this literary form had been borrowed from the Italians, he expected to achieve a success as great as that which he supposed to be already his in the fields of pastoral romance and epic poetry. But in this instance at least the "científico" was completely defeated by the "lego"; Lope's novels have none of the grace, naturalness, or interest which characterize those of his rival. The last important work which has to be mentioned before we leave the narrative poetry of Lope is the *Laurel de Apolo* (1630). This piece describes the coronation of the poets of Spain on Helicon by Apollo. All of them—good, middling, and bad—share in the ceremonial, and among the poets properly so called appear some other men of letters, certain important personages to whom Lope felt under obligations, which could not be more satisfactorily paid than in the current coin of verse which he had so readily at his command. This work is more meritorious as a bibliographical manual of Spanish poetry at that time than as genuine poetry. One other "obra suelta," closely akin to Lope's dramatic works, though not properly speaking a drama, is *La Dorotea* (1632). Lope describes it as an "action in prose," but it is rather a "romance in dialogue"; for, although divided into acts, the narrative has nothing dramatic about it except its outward form; and on account of its size and the digressions with which it is encumbered it has never succeeded in finding its way to the stage. It belongs to the class of which *Celestina* is the type, in so far as one of the principal characters, La Gerarda, is a go-between; but Lope has amplified his model, idealized it, and purged away much of the grossness belonging to the mean surroundings of the character of the original *Celestina* and common to the numerous works of the 16th and 17th centuries to which it gave rise. Of all Lope's productions *Dorotea* is undoubtedly that which shows most observation and study; the style also is unusually simple and easy. The attempt has sometimes been made to discover in the adventures of Fernando, one of its heroes, allusions to Lope's early youth; but there is nothing conclusive in any of the supposed coincidences between fact and fiction which Fauriel and others after him have sought to establish. Of all this mass of *Obras Sueltas*, filling more than twenty volumes, very little (leaving *Dorotea* out of account) holds its own in the impartial judgment of posterity. The long epic or narrative poems are quite unreadable, and almost the same must be said of the pastorals and novels. The lyrical element alone retains some vitality. From the *Rimas* and other collections of detached pieces one could compile a pleasing anthology of sonnets, epistles, elegies, and romances, to which it would be proper to add the *Gatomaquia*, a burlesque poem published along with other metrical pieces in 1634 by Lope under the pseudonym of Tomé de Burguillos. But here the list would have to stop.

It is, however, to his dramatic writings that Lope owes his very considerable place in literary history. It is very curious to notice how he himself seizes every available occasion for depreciating the work of the drama, treats the art of comedy-writing as one of the humblest of trades (*de pane lucrando*), and protests against the supposition that in writing for the stage his aim is glory and not money.[1] The reason is not far to seek. The Spanish drama, which, if not literally the creation of Lope, at least owes to him its definitive form—the three-act comedy—was totally regardless of the precepts of the school, the pseudo-Aristotelianism of the doctors of the period. Lope accordingly, who stood in awe of the criticisms of the "científicos," felt bound to let them see that, from the point of view of literary art, he attached no value to the "rustic fruits of his humble *vega*." In his *Arte Nuevo de Hacer Comedias en Este Tiempo*, which was published in 1609 and is the *Ars Poetica* of the new school, Lope begins by showing that he knows as well as any one the established rules of poetry, and then excuses himself for his inability to follow them on the ground that the "vulgar" Spaniard cares nothing about them. "Let us then speak to him in the language of fools, since it is he who pays us." Under such conditions all that the dramatic poet can do is to plan ingenious plots, so as adroitly to sustain the interest and retard as long as possible the denouement, for nothing is more displeasing to the ordinary public than to be able to divine too soon the solution of the problem set before them on the boards of the theatre. Such, with a few pieces of advice as to the choice of metres and the costume of the actors, is the recipe for the new or free comedy, a barbarous kind of literature, according to Lope, and outside the region of art, yet the only drama possible in Spain.[2] Another reason, more serious still, which made it necessary for him to speak deprecatingly of his dramatic works is the circumstance that the vast majority of them were written in haste and to order, precisely like so many feuilleton romances of Alexandre Dumas; they are for the most part *comedias de repente*, hurriedly conceived at the request of some grandee or of some impresario or manager. The poet does not hesitate to confess that "more than a hundred of my comedies have taken only twenty-four hours to pass from my brain to the boards of the theatre." Perez de Montalban, who has a great admiration for this kind of cleverness, tells how, at Toledo, on a certain occasion, Lope composed fifteen acts in fifteen days—that is to say, five entire comedies, which he read to his friends step by step with the process of their composition. On another occasion, when pressed by a manager who wanted something for the carnival, Lope took Montalban as a collaborateur; the two friends parcelled out the comedy between them, Lope undertaking the first act, Montalban the second, and the third, to save time, was divided between them. In two days they had finished the first two acts, and on the third Montalban rose at two in the morning and at eleven he had finished. Then he went in search of Lope, who, when questioned as to his progress, replied: "I got up at five, finished the act, breakfasted, wrote an epistle of fifty tercets, and have now finished watering the garden, and a rather tough business it has been." This is not art; it is handicraft, and one understands why Lope sometimes found it prudent to lay stress on the fact that his comedies had been written for the ears of spectators, not for readers in their studies.[1] Nevertheless, he did write some dramas in which the plan is more fully matured and the execution more carefully carried out; still, hurried composition and reckless production are after all among the most distinctive marks of his theatrical works. Towards the close of his career Lope somewhat modified the severe and disdainful judgments he had formerly passed upon his dramatic performances; he seems to have had a presentiment that posterity, in spite of the grave defects of his work in that department, would nevertheless place it much higher than the *Jerusalem Conquistada*, *La Dragontea*, and other works of which he himself thought so much. In his *Egloga á Claudio*, which is, so to say, his literary last will and testament, he claims to have been a creator: "It is to me that the art (of comedy) owes its beginnings, although I have departed from the strictness of Terence, and do not for a moment pretend to deny the part which belongs to the three or four great geniuses who have watched over the infancy of the drama. To whom are we indebted, Claudio, for so many delineations of love and jealousy, so many moving pieces of eloquence, such a copious supply of all the figures which rhetoric has ever been able to invent? All that is produced to-day is nothing but imitation of what art created yesterday. The path—it is I who have opened it up and made it practicable, and everybody now traverses it with ease. It was I who gave the example which is followed and copied on all hands." We may certainly credit Lope with creative power, with the instinct which enabled him to reproduce the facts of history or those supplied by the imagination in a multitude of dramatic situations with an astonishing cleverness and flexibility of expression; but unfortunately, instead of concentrating his talent upon the production of a limited number of works which he might have brought to perfection, he dissipated it, so to say, and scattered it to the winds.

[1] Algunos que piensan que las escribo por opinion; desengañeles V. M. y digales que por dinero.

[2] Las comedias de España no guardan el arte . . . porque con aquel rigor de ninguna manera fueran oidas de los Españoles.

The catalogue of Lope's comedies has been drawn up by himself; and, in spite of some discrepancies in his figures, it is established that up to 1604 he had composed, in round numbers, as many as 230. In 1609 the figure had risen to 500, in 1618 to 800, in 1620 to 900, in 1625 to 1070, and in 1632 to 1500. Ultimately Montalban in his general survey published in 1636 (*Fama Posthuma*) set down the total of Lope's dramatic productions at 1800 comedies and 400 *autos sacramentales*. Of this number there are nearly 608 comedies of which the text is extant, or which are at least known to us by their titles (from the lists of the *Peregrino*); but the printed or MS. text of only 439 is actually accessible, besides some 40 *autos* and a few *entremeses*. Very many of these pieces were printed during Lope's lifetime, either in collections of *varios autores* or as separate issues by booksellers who bought from the actors in an underhand way the manuscripts of their *rôles* or else caused the unpublished comedy to be written down from memory by persons whom they sent to attend the first representation. Such pieces therefore as do not figure in the collection published under Lope's own direction or under that of his friends cannot be regarded as perfectly authentic, and it would be unfair to hold their author responsible for all the faults and defects they exhibit. On the other hand, there exist in various libraries entire comedies in Lope's own handwriting which have never been printed.

The classification of this enormous mass of dramatic literature is a task of great difficulty, inasmuch as the terms usually employed, such as comedy, tragedy, and the like, do not apply here. There is not explicitness enough in the division current in Spain, which recognizes three categories: (1) *comedias de capa y espada*, the subjects of which are drawn from everyday life and in which the persons appear as simple *caballeros*; (2) *comedias de ruido* or *de teatro*, in which kings and princes are the leading characters and the action is accompanied with a greater display of dramatic machinery; (3) *comedias divinas* or *de santos*. Some other arrangement must be attempted. In the first place Lope's work belongs essentially to the drama of intrigue; be the subject what it may, it is always the plot that determines everything else, not the delineation of manners or of character. Lope in the whole range of his dramatic works has not a single piece comparable to *La Verdad Sospechosa* of Alarcon, the most finished example in Spanish literature of the comedy of character; and what is called the comedy of manners is no better represented: only *El Rufian Castrucho*, *El Anzuelo de Fenisa*, and one or two others can be named. It is from history, and particularly Spanish history, that he has borrowed more than from any other source. It would in fact be difficult to say what national and patriotic subjects, from the reign of the half fabulous King Pelayo down to the history of his own age, he has not put upon the stage. Sometimes he contents himself with serving up old chronicles afresh or stringing together fragments of old popular songs, as in *El Bastardo Mudarra*, with inventing here and there a few secondary characters when the original material is not sufficiently rich and complicated, as in *Las Doncellas de Simancas*, *Los Benavides*, *El Casamiento en la Muerte*, and many others, or sometimes even with clothing with complete dramatic action one single fact of history, as in one of his most famous plays, *La Estrella de Sevilla*, in *Porfiar hasta Morir*, in *El Mejor Alcalde el Rey*, and others. Even current events as they took place under his eyes furnished him with motives. In an age when people read but little, the theatre was a channel of information and a means of rousing patriotic sentiment. A victory of the Spanish arms in Flanders or the success of hardy adventurers in planting the royal banner of Castile in some virgin land in the West,—events like these promptly gave rise to a comedy. On the basis of any sort of report of battle or conquest Lope improvises a dramatic action, or at least a narrative in dialogue. Thus under the title of *La Mayor Victoria de Alemania* he describes a victory won in the Palatinate by Don Gonzalo de Córdoba, brother of the duke of Sesa, his patron. Such are the principal varieties of historical or heroic comedy. But it is to the class of *capa y espada*—also called *novelesco*, because the subjects are almost always love intrigues complicated with affairs of honor—that Lope's most celebrated plays belong. In these he has most fully displayed his powers of imagination (the subjects being all invented) and his skill in elaborating a plot. Among the plays of this class which are those best known in Europe, and most frequently imitated and translated, may be specially mentioned *Los Ramilletes de Madrid*, *La Boba para los Otros y Discreta para sí*, *El Perro del Hortelano*, *La Viuda de Valencia*, and *El Maestro de Danzar*. In some of them Lope has sought to set forth some moral maxim, and illustrate its abuse by a living example. Thus, on the theme that "poverty is no crime," we have the play entitled *Las Flores de Don Juan*, in which he shows in the history of two brothers the triumph of virtuous poverty over opulent vice; at the same time he attacks indirectly the institution of primogeniture, which often places in the hands of an unworthy person the honor and substance of a family when the younger members would be much better qualified for the trust. Such pieces are, however, rare in Lope's repertory; in common with all other writers of his order in Spain, with the occasional exception of Alarcon, his sole aim is to amuse and stir his public, not troubling himself about its instruction. The strong point of such writers is and always will be their management of the plot. As has been said by Le Sage, a good judge: "The Spaniards are our masters in the art of planning and skilfully working out a plot; they know how to set forth their subject with infinite art and in the most advantageous light." It is not necessary to dwell here upon the other varieties of comedy represented in Lope's works, that is, the *comedias divinas*, *fiestas* (mythological dramas for the most part), *entremeses*, and *autos*. In none of them has he produced anything of the highest order, or even comparable to the better performances of his contemporaries and successors.

To sum up, Lope found a poorly organized drama, plays being composed sometimes in four acts, sometimes in three; and, though they were written in verse, the structure of the versification was left far too much to the caprice of the individual writer. The style of drama then in vogue he adopted, because the Spanish public liked it. The narrow framework it afforded he enlarged to an extraordinary degree, introducing everything that could possibly furnish material for dramatic situations,—the Bible, ancient mythology, the lives of the saints, ancient history, Spanish history, the legends of the Middle Ages, the writings of the Italian novelists, current events, Spanish life in the 17th century. Before him manners and the conditions of persons and characters had been barely sketched; with fuller observation and more careful description he created real types; and gave to each social order the language and drapery appropriate to it. The old comedy was awkward and poor in its versification; he introduced order into the use of all the forms of national poetry, from the old romance couplets to the rarest lyrical combinations borrowed from Italy. Hence he was justified in saying that those who should come after him had only to go on along the path which he had opened up. Calderon notably, whose merit has been much exaggerated, especially since the Germans took him under their protection, is merely a pupil and inferior to his master; at all events, his indebtedness to the latter is enormous and has not as yet been adequately recognized.

[1] No las escriví . . . para que de los oydos del teatro se trasladáran á la censura de los aposentos.

Bibliography.—For the life of Lope, see Juan Perez de Montalban's *Fama Posthuma* (4to, Madrid, 1636; reprinted in *Bibl. Rivadeneyra*); La Barrera, *Catálogo del Téatro Antiguo Español;* Von Schack, *Geschichte der dramatischen Literatur und Kunst in Spanien*, vol. ii.; and *Ultimos Amores de Lope de Vega Carpio* (8vo, Madrid, 1876),an extract by Francisco Asenjo Barbieri from an unpublished biography written by La Barrera in connection with the poet's correspondence with the duke of Sesa. For Lope's literary theories and doctrine of dramatic art, reference may be made to Menéndez-Pelayo, *Historia de las Ideas Estéticas en España*, and to A. Morel-Fatio, *La Comédie Espagnole du XVII^{me} Siècle* (8vo, Paris, 1885). The *Obras Sueltas* were published by Francisco Cerdá y Rico (21 vols. 4to, Madrid, 1776–79). For the bibliography of the comedies, see La Barrera. The selection of comedies published by Hartzenbush in four volumes in the *Biblioteca Rivadeneyra* is fairly good; but the same cannot be said of its choice of *Obras Sueltas*. (A. M.-F.)

VEGA, GARCILASO DE LA. See GARCILASO.

VEGETABLE KINGDOM.[1] There is one peculiar factor which enters into the problem of the classification of plants and materially adds to its complexity. It is the polymorphism of the individual; that is, the life-history is usually complex, the individual assuming different forms in various stages of its life-history. Thus, in the great majority of plants there is a well-marked alternation of generations,—an alternation, that is, of a sexual form, the *gametophyte*, with an asexual form, the *sporophyte* (see REPRODUCTION, vol. xx. pp. 436–8). And not only so, but in many cases one or other of these generations presents a number of different forms. Hence the true affinities of any individual cannot be regarded as satisfactorily ascertained unless its life-history is fully known; and, since in most cases the various forms are perfectly separate, and often quite dissimilar, there is difficulty in obtaining all the information necessary for determining the true systematic position of a plant,—a difficulty which has not yet been overcome in very many cases.

Comparatively little light is thrown on the affinities of existing plants by the information which has been accumulated with regard to the extinct fossil forms. In no case can the genealogy of an existing plant be traced as in the case of the horse among animals (see ANIMAL KINGDOM).

The vegetable kingdom is usually divided into the four following sub-kingdoms: I. THALLOPHYTA; II. BRYOPHYTA; III. PTERIDOPHYTA; IV. PHANEROGAMIA (SPERMAPHYTA).

All of these, except some *Thallophyta*, present a more or less clearly marked alternation of generations. In all cases the more conspicuous form is considered to be "the plant." Thus, in the *Thallophyta* generally the plant is the gametophyte, the sporophyte being comparatively inconspicuous and in many cases merely an appendage on the gametophyte; in the *Bryophyta* likewise the gametophyte is the plant, the sporophyte being an appendage on the gametophyte. In the *Pteridophyta* and in the *Phanerogamia* the plant is the sporophyte, the gametophyte being comparatively inconspicuous. In the *Pteridophyta* the gametophyte is still an independent organism; but in ascending from the lower to the higher forms it becomes more and more reduced. In the *Phanerogamia* the gametophyte is still further reduced and becomes a mere appendage on the sporophyte.

SUB-KINGDOM I. THALLOPHYTA.

This sub-kingdom includes the most lowly organized of plants. They are characterized by the total absence, or the imperfection, of that differentiation of the body into root, stem, and leaf which is so marked a feature in the higher plants, and by the simplicity of their internal structure, especially by the absence of woody vascular tissue. In those *Thallophyta* which present an alternation of generations the gametophyte is generally the more conspicuous, constituting the plant. The gametophyte is commonly capable of producing spores, not only sexually, but also asexually.

The sub-kingdom is naturally divided into two main classes, the ALGÆ or SEA-WEEDS and the FUNGI, to which may be added, as a subsidiary group, the LICHENS. It is becoming usual to regard the *Algæ* and *Fungi* as distinct sub-kingdoms; but it is preferable, as they have so much in common, to continue to regard them as classes of the sub-kingdom *Thallophyta*.

CLASS I. ALGÆ.—There is so much variety in the form and structure of the *Algæ* (see article ALGÆ) that no more precise definition of them can be given than that they are Thallophytes which contain chlorophyll (see PHYSIOLOGY, vol. xix. p. 59). Though they characteristically live in water, this is by no means universally the case, for the natural habitat of many of them is damp soil. All *Algæ* contain chlorophyll, but many of them contain other coloring-matters in addition,—a feature which forms a convenient basis for classification. On this basis the *Algæ* are classified into the four following sub-classes:

I. **Cyanophyceæ**, containing a bluish coloring-matter, *phycocyanin*, and having a blue-green color.
II. **Chlorophyceæ**, green *Algæ*, containing no coloring-matter, except chlorophyll and its derivatives.
III. **Phæophyceæ**, containing a yellow or brown coloring-matter, *phycophæin*, and having a brown color.
IV. **Rhodophyceæ**, containing a red coloring-matter, *phycoerythrin*, and having a red or purple color.

These four sub-classes are by no means coextensive. The *Cyanophyceæ* include only very simple forms; the *Chlorophyceæ* and the *Phæophyceæ* include a series of forms from the simplest to the most complex; the *Rhodophyceæ* include only forms which, though their vegetative structure is frequently very simple, are comparatively highly developed as regards their reproductive organs.

Sub-Class I. **Cyanophyceæ**, or Blue-Green *Algæ*.—The body may consist of a single, more or less nearly spherical cell, as in most of the *Chroococcaceæ* (*e.g.*, *Glœocapsa*), or it may be a multicellular layer one cell thick (*e.g.*, *Merismopedia*), or it may be filamentous, consisting of a single row of cells, as in *Rivularia*, *Nostoc*, *Oscillaria*. When the body is filamentous, it sometimes presents a distinction of base and apex, as in *Rivularia*; and it is frequently branched, the branching being either spurious (*e.g.*, *Scytonema*) or true (*e.g.*, *Sirosiphon*). In most cases growth and cell-division go on in all the cells of the body, but in the *Scytonemeæ* and *Sirosiphoneæ* only at the apices. A characteristic feature of the sub-class is the more or less bulky mucilaginous cell-wall which invests the cells and filaments.

Reproduction is mainly effected in a purely vegetative manner. In the unicellular forms each cell-division necessarily leads to the formation of new individuals. In the flattened forms (*e.g.*, *Merismopedia*), when the body reaches a certain limit of size, it simply breaks up into a number of separate portions. In the filamentous forms the body is marked out into segments by inert cells, termed *heterocysts*, which are quite different in appearance from the living cells of the filament. Eventually these segments, termed *hormogonia*, separate, and, escaping from the mucilaginous matrix, develop by growth and cell-division into new individuals. In many cases special reproductive cells, *spores*, are developed. Each spore is formed from a single cell of the body, which surrounds itself with a thick firm wall of its own. It is probable that ciliated spores, *zoospores*, are produced, but the existing observations on this point are inconclusive. There is no evidence of the existence of any form of sexual reproduction in this group.

The *Cyanophyceæ* are divided into a number of orders:

Order 1. *Chroococcaceæ*.
" 2. *Nostocaceæ*.
" 3. *Oscillariaceæ*.
Order 4. *Rivulariaceæ*.
" 5. *Scytonemeæ*.
" 6. *Sirosiphoneæ* (*Stigonemeæ*).

It is doubtful to what extent these orders really represent distinct forms; for there is some evidence that certain

---

[1] The problem of classification being essentially the same in the animal and vegetable kingdoms, the reader is referred to the general discussion of it in the article ANIMAL KINGDOM.

Cyanophyceæ assume the different forms characteristic of several of these orders at various stages of their development and under various external conditions: in other words, some, at least, of the *Cyanophyceæ* are polymorphic, and this necessarily renders their classification difficult.

The *Cyanophyceæ* resemble the *Schizomycetes* (*Fungi*) in many respects, as, for instance, in their general structure, in their simple vegetative reproduction and in their spore formation, in the production of a bulky mucilaginous matrix, and in their polymorphism. On these grounds they are frequently placed along with the *Schizomycetes* in a distinct class under the name *Schizophyta*. But this arrangement does not seem to secure any special advantage. It is simpler to regard the *Cyanophyceæ* and the *Schizomycetes* as parallel groups, the one belonging to the *Algæ*, the other to the *Fungi*.

Sub-Class II. **Chlorophyceæ.**—The body may consist of a single cell (*e.g.*, *Protococcoideæ*), or it may be multinucleate and unseptate (*e.g.*, *Siphoneæ*), or septate and therefore multicellular (*e.g.*, *Characeæ*). It presents all degrees of morphological differentiation: thus, it may be spherical (as in *Hæmatococcus* and in *Volvox*), or flattened (as in *Ulva*), or filamentous (as in *Spirogyra*, *Ulothrix*, etc.), with a differentiation of root and shoot (as in *Œdogonium*); or it may even present rudimentary differentiation into stem, leaf, and root, as in the *Siphoneæ* (*e.g.*, *Caulerpa*) and *Characeæ*. The structure of the body is peculiar in the *Hydrodictyeæ*, being composed of a number of originally separate cells; such a body is termed a *cœnobium*.

Vegetative multiplication, though not universal, is not uncommon in this sub-class. Reproduction by means of asexually-produced spores is very general, and the spores are commonly ciliated zoospores. A sexual process has been observed in members of every order of this sub-class. It consists either in the fusion of similar sexual cells, when it is said to be *isogamous*; or a large non-motile female cell (oosphere) is fertilized by a small motile male cell (antherozoid), when it is said to be *oogamous*. The isogamous process usually takes place between free-swimming ciliated cells (*planogametes*); but in the group of the *Conjugatæ* it takes place between gametes which are not set free into the water and are not ciliated (see REPRODUCTION). In those *Chlorophyceæ* in which both sexual and asexual spore-formation occurs, there is generally a distinction of sexual and asexual forms, so that the life-history presents an alternation of generations. Thus, in *Acetabularia* the plant is the sporophyte, producing asexually non-motile spores, which on germination give rise to sexual reproductive cells or gametes. Each of these spores represents a sexual form or gametophyte. Again, in *Coleochæte* the plant is the gametophyte, producing the sexual organs, the sporophyte being represented by a small flattened plate of cells, developed from the fertilized female cell or oospore, which never produces any sexual organs, but only spores.

The *Chlorophyceæ* may be classified as follows:

Order 1. *Protococcoideæ.*—Unicellular plants; the body frequently spherical and unattached, but presenting in some forms a distinction of base and apex, and then it is attached by the base. Reproduction by vegetative division, or by zoospores, or by a sexual process, the sexual cells being similar planogametes. This order may be divided into two families,—the *Protococcaceæ* and the *Palmellaceæ*, the distinction being that in the latter the cell-walls are swollen and mucilaginous, so that the cells are held together, whereas in the former the cells are free. Vegetative multiplication by division is universal in the *Palmellaceæ*, but is commonly wanting in the *Protococcaceæ*.

Order 2. *Volvocineæ.*—Unicellular or multicellular plants; body free-swimming by means of cilia, either spherical or a flat plate.

a. Isogamous forms: Pandorina, *Stephanosphæra* (spherical), *Gonium* (flattened).
b. Oogamous forms: Volvox, *Eudorina*, *Chlamydomonas* (unicellular).

Order 3. *Hydrodictyeæ.*—Multicellular plants; body unattached, a net (*Hydrodictyon*) or a flat plate (*Pediastrum*), formed by the combination of originally separate cells (a *cœnobium*). The sexual process is isogamous.

Order 4. *Siphoneæ.*—Unseptate multinucleate plants; body vesicular and unbranched, or filamentous and branched, assuming most various forms, presenting distinction of base and apex, attached by base; sometimes (*Caulerpa*) presenting differentiation into root, stem, and leaf. The sexual process is isogamous or oogamous.

a. Isogamous forms: Codieæ, *Dasycladeæ*, *Caulerpeæ*, *Botrydieæ*.
b. Oogamous forms: Vaucheriaceæ.

Order 5. *Confervoideæ.*—Septate multicellular plants (body unicellular in some Desmids); cells uni- or multinucleate; body filamentous, branched or unbranched, sometimes presenting distinction of root and shoot, and then attached by the root, or a flat plate or hollow tube of cells. The sexual process is isogamous or oogamous.

a. Isogamous forms—
α. Gametes not free-swimming or ciliated: *Conjugatæ* (including *Desmidieæ*, *Mesocarpeæ*, *Zygnemeæ*).
β. Gametes free-swimming and ciliated.
Body filamentous, unbranched: *Ulothricaceæ*.
Body filamentous, branched: *Cladophoreæ*, *Chætophoreæ*.
Body a flat or tubular layer of cells: *Ulvaceæ*.
b. Oogamous forms: body filamentous—
α. Sexual organs undifferentiated: *Sphæropleæ*.
β. Sexual organs differentiated.
Œdogonieæ; body unbranched (except *Bulbochæte*); oogonium without trichogyne; sporophyte, a single cell (oospore).
Coleochæteæ; body branched; oogonium with trichogyne; sporophyte multicellular.

Order 6. *Characeæ.*—Multicellular plants; body presenting differentiation into leaf, stem, and root. There is no asexual production of spores; the sexual process is oogamous, the sexual organs being highly differentiated.

The distinction of the genera, and to some extent also that of the orders, is rendered difficult in many cases by polymorphism. For instance, it has been ascertained that many plants which have been referred to the *Protococcoideæ* are simply forms of some of the *Confervoideæ*, *Siphoneæ*, etc.; and similarly some of the *Ulvaceæ* have Ulothricoid forms. Still, there can be no doubt that each of the above orders includes some autonomous forms.

With regard to the affinities and phylogeny of the orders of *Chlorophyceæ*, the *Protoccoideæ* must be taken as the starting-point from which the other orders have sprung, their evolution having taken place in various directions. Beginning with the simple spherical *Protococcaceæ*, the origin of the *Volvocineæ* from these by cell-division can be readily traced through *Chlamydomonas*, the higher forms being simply motile multicellular *Protococcaceæ*. Closely allied to the *Volvocineæ* are the *Hydrodictyeæ*. The *Siphoneæ* can be readily traced back to the simplest *Protococcaceæ* through the attached *Protococcaceæ*, such as *Characium*. The *Confervoideæ* are probably also derived from the *Protococcaceæ;* and a certain relationship between some members of this order—the *Cladophoreæ*—and the *Siphoneæ* is indicated by the multinucleate cells of the former. Thus, *Valonia*, which is septate, and therefore really belongs to the *Confervoideæ*, closely resembles some of the *Siphoneæ* in its general habit. The phylogeny of the *Characeæ* is obscure, but it is probable that they have sprung from the *Confervoideæ*, possibly from the *Cladophoreæ*. It is of interest to note that the large cells of the *Characeæ* become multinucleate.

Sub-Class III. **Phæophyceæ.**—The form of the body is very various; it may consist of a single cell; when multicellular it may be filamentous and branched, or a flattened expansion, or cylindrical or vesicular, hollow or solid. It presents also various degrees of morphological differentiation: in some forms it is quite undifferentiated; in others it presents a differentiation of base and apex, and is then attached by the base; in others it presents indications of differentiation into root, stem, and leaf. Vegetative multiplication is common only in the lowest forms; in the higher it occurs in some cases, and is effected by the abstriction of modified members of the parent, termed *gemmæ*. The existence of a sexual process has been ascertained in several forms; but in many others further investigation is required to determine its presence or absence. In those forms in which it occurs it may be either isogamous or oogamous; the isogamous process may take place between free-swimming gametes, or between gametes which are not free-swimming or ciliated. The life history of the plants of this group is imperfectly known; but it has been ascertained that in some there is, and in others there is not, an alternation of generations.

The *Phæophyceæ* may be classified as follows:

Order 1. *Diatomaceæ.*—Unicellular plants, either free, or connected into filaments or masses by mucilage. Reproduction, vegetative by division or by means of asexually-produced spores (*auxospores*); or sexual isogamous by the fusion of nonciliated gametes. The cell-wall is impregnated with silica.

Order 2. *Syngeneticæ.*—Body unicellular, the cells being held together by mucilage. Reproduction by division and by asexually-produced spores. The order includes two forms, *Chromophyton* and *Hydrurus*. The former is distinguished by being unattached and by the motility of its spores, which have a single long cilium. *Hydrurus* grows attached, and the spores are not motile.

Order 3. *Phæosporeæ.*—Multicellular plants; the body is filamentous and branched or flattened, always presenting differentiation of base and apex, and in some cases more or less well-marked differentiation into root, stem, and leaf, usually attached by the base. Reproduction vegetative by gemmæ or by means of asexually-produced zoospores, or by a sexual process which is essentially isogamous, the gametes being ciliated, but in the higher forms tending to become oogamous. The principal families of the *Phæosporeæ* are *Ectocarpeæ*, *Sphacelarieæ*, *Mesoglœaceæ*, *Desmarestieæ*, *Scytosiphoneæ*, *Cutleriaceæ*, and *Laminarieæ*. The filamentous type of structure obtains in the *Ectocarpeæ*, *Sphacelarieæ*, *Mesoglœaceæ*, and *Desmarestieæ*. The filaments may consist of single rows of cells (*monosiphonous*), as in most *Ectocarpeæ*, or of several rows of cells (*polysiphonous*), as in the *Mesoglœaceæ;* or they may be polysiphonous with a more or less well-developed cortical layer, as in the *Sphacelarieæ*, in which case there is also a large apical cell. The structure of the *Desmarestieæ* (*e.g.*, *Desmarestia* and *Arthrocladia*) is similar to that of the *Sphacelarieæ*, but the growing point is not apical, as in the *Sphacelarieæ*, but intercalary, as in the *Ectocarpeæ*. In some of these forms (*e.g.*, *Cladostephus* among the *Sphacelarieæ*) there is an indication of the differentiation of the shoot into stem and leaf. The type of structure obtaining in the *Scytosiphoneæ*, *Cutleriaceæ*, and *Laminarieæ* is that of a flattened expansion of parenchymatous tissue, though in the *Laminarieæ* there is a certain degree of histological differentiation, as indicated by the presence of elongated cells forming structures resembling the sieve-tubes of the vascular plants. In some of the *Scytosiphoneæ* there is a large internal cavity, so that the body presents a cylindrical or vesicular form. Vegetative reproduction by gemmæ is only known in the *Sphacelarieæ*. Reproduction by means of asexually-produced spores (zoospores) is known to occur in the majority of the *Phæosporeæ*, but it has not yet been detected in some forms (*e.g.*, *Arthrocladia*, *Scytosiphon*, *Phyllitis*, *Colpomenia*). The asexual organs are unilocular sporangia. The sexual organs (*gametangiæ*) are multilocular. They have been found in all the families except the *Laminarieæ*, but not yet in all the genera (*e.g.*, *Asperococcus*). The gametangia are all quite similar, except in the *Cutleriaceæ* and in *Tilopteris* (a genus allied to *Desmarestia*), in which also the gametes differ in appearance. A sexual process has only been observed in a few species of *Ectocarpeæ* and *Scytosiphoneæ* (*Ectocarpus siliculosus* and *E. pusillus*, *Giraudia sphacelarioides*, *Scytosiphon lomentarius*), and in the *Cutleriaceæ*. A full account of the sexual process in these forms is given in the article REPRODUCTION, vol. xx. p. 439.

Order 4. *Dictyotaceæ.*—Body multicellular, thalloid, flattened, ribbon-like, as in *Dictyota*, *Phycopteris*, *Dictyopteris*, or broader and fan-shaped, as in *Taonia*, *Padina*, *Zonaria;* usually attached by the base, but by root-hairs developed on the under surface in *Zonaria*. Asexual reproduction by spores, formed four (*tetraspores*) in each unilocular sporangium; spores not motile. Though a sexual process has not been observed, there are apparently male and female organs,—antheridia and oogonia. The supposed male cells are set free and are not motile; the supposed female cells are not set free. The sporangia and the sexual organs are borne on distinct individuals, and in some genera (*e.g.*, *Dictyota*, *Taonia*) the male and female organs are borne on distinct individuals.

Order 5. *Fucaceæ.*—Body multicellular; generally differentiated into root and shoot; shoot usually thalloid, cylindrical, or flattened, but differentiated into stem and leaves in *Sargassum*. No asexual production of spores. Sexual organs antheridia or oogonia. Male cells numerous, set free, ciliated; female cells (oospheres) either one (*Pycnophycus*, *Himanthalia*, *Cystoseira*, *Sargassum*), two (*Pelvetia*), four (*Ozothallia*), or eight (*Fucus*) in an oogonium, set free, not motile.

The life-history of the *Phæophyceæ* is in most cases imperfectly known. In the *Fucaceæ*, since there is no asexual formation of spores, there is no alternation of generations, and there is no indication of any other kind of polymorphism. In those forms in which the sexual and asexual organs are restricted to separate individuals, as in *Cladostephus* (*Sphacelarieæ*), in the *Cutleriaceæ*, and in the *Dictyotaceæ* there may be an alternation of generations. In the *Cutleriaceæ* it is, in fact, highly probable. In the one genus, *Zanardinia*, the two generations are similar, differing only in the nature of their reproductive organs. In *Cutleria*, the other genus, the two generations are dissimilar, the form known as *Cutleria* being the gametophyte, whereas the sporophyte appears to be a form which has been regarded as a distinct genus, under the name of *Aglaozonia*. In some genera of *Dictyotaceæ* (*Taonia*, *Padina*, *Dictyopteris*), there is a further indication of polymorphism, in that the spore (whether tetraspore or oospore) produces on germination a spherical or cylindrical protonematoid body, from which spring the shoots of the characteristic form.

Since the life-history of the *Phæophyceæ* is so imperfectly known, the relations of the various orders cannot be accurately determined. The *Diatomaceæ* and the *Syngeneticæ* are apparently isolated groups. The families of the *Phæosporeæ* form a series leading from the simple isogamous *Ectocarpeæ* through the *Cutleriaceæ* to the oogamous *Fucaceæ*. There are also points of resemblance in the vegetative parts between some of the *Scytosiphoneæ* and the *Laminarieæ*.

Sub-Class IV. **Rhodophyceæ.**—This sub-class includes the single order *Florideæ*.

Order Florideæ.—Multicellular plants; body flattened or filamentous; when filamentous, either monosiphonous or polysiphonous, with or without a cortex; thalloid, or with indications of differentiation into stem and leaf. Asexual reproduction, by means of unciliated naked spores, which are usually tetraspores (wanting in *Lemanea*), produced in unilocular sporangia. Sexual reproduction by means of male and female organs, termed antheridia and procarpia; the procarpium is generally multicellular, but sometimes unicellular (*Bangiaceæ*, *Nemalieæ*), is always closed, and generally consists of two parts, the *carpogonium* or sporogenous portion and the *trichogyne* or receptive portion. The male cells are non-motile and have a cell-wall (*spermatia*); there is no differentiated female cell in the procarpium. After fertilization the carpogenous cell (or cells) divides to form the mother-cells of spores, and each mother-cell gives rise to a single naked spore (*carpospore*), which is not ciliated and is usually non-motile; in the *Bangiaceæ* the carpospores exhibit amœboid movements for a time. The group of sporogenous cells formed from the fertilized carpogenous cell (or cells) is termed a *cystocarp;* in many cases these cells become surrounded by an investment developed from the adjacent vegetative tissue. The structure of the cystocarp is very simple in the *Bangiaceæ*, consisting only of eight spore mother-cells. The principal orders of the *Florideæ* are *Bangiaceæ*, *Lemaneaceæ*, *Nemalieæ*, *Ceramiaceæ*, *Corallineæ*, *Rhodomelaceæ*, *Cryptonemiaceæ*, *Rhodymeniaceæ*, *Wrangeliaceæ*, *Squamariaceæ*, *Sphærococcaceæ*.

With regard to the life-history of the *Florideæ*, it is generally considered to present a well-marked alternation of generations, the plant being the gametophyte, the fructification (cystocarp) formed in consequence of fertilization being the sporophyte. Further polymorphism has been detected in the genera *Lemanea* and *Batrachospermum*. Here the carpospore does not at once give rise to the plant, but to a filamentous or flattened body, which in *Batrachospermum* reproduces itself by spores, and from which the parent form springs as lateral branches. This filamentous form appears to be identical with species of the genus *Chantransia;* it is therefore known as the *Chantransia*-form.

Mutual Affinities and Phylogeny of Sub-Classes of Algæ.

Comparison of the four sub-classes shows that, whereas the *Chlorophyceæ* and the *Phæophyceæ* present two fairly complete series of parallel forms, ranging from unicellular undifferentiated to multicellular more or less highly differentiated organisms, the *Cyanophyceæ* consist only of comparatively simple forms in which sexual reproduction is unknown, and the *Rhodophyceæ* of comparatively complex forms in all of which a sexual process obtains. It has been suggested by Cohn, Berthold, and others that there is a close relation between the lowest *Rhodophyceæ* (*Bangia*) and the higher filamentous *Cyanophyceæ* (*Scytonemeæ*, *Sirosiphoneæ*), and that possibly the latter may have been derived from the former. On this view the *Cyanophyceæ* and the *Rhodophyceæ*, taken together, constitute a series which is on a level with those of the *Chlorophyceæ* and of the *Phæophyceæ*. On comparing these three series together, it will be observed that they present a general correspondence, in that the main types of form are to be found in all. Thus, the *Chroococcaceæ* among the *Cyanophyceæ*, the *Palmellaceæ* among the *Chlorophyceæ*, and the *Syngeneticæ* among the *Phæophyceæ* are corresponding groups; similarly the *Confervoideæ* among the *Chlorophyceæ* correspond to the *Ectocarpeæ* and other filamentous *Phæophyceæ*, and to various forms of *Rhodophyceæ*, such as *Bangia*, *Porphyra*, *Griffithsia*, and *Callithamnion;* and *Chara* (*Chlorophyceæ*) resembles, at least in its vegetative structure, such forms as *Cladostephus* (*Phæophyceæ*) and *Polysiphonia* (*Rhodophyceæ*). There are, however, forms belonging to some of the sub-classes which have no representatives in others. Thus the orders *Siphoneæ*, *Volvocineæ*, *Hydrodictyeæ*, belonging to the *Chlorophyceæ*, are unrepresented in the other sub-classes, and this is true also of the *Fucaceæ* and the *Laminarieæ* among the *Phæophyceæ*. The Conjugate *Chlorophyceæ* also form a peculiar group, the only corresponding forms being the *Diatomaceæ* (*Phæophyceæ*), which present many points of resemblance to the *Desmidieæ*.

With regard to the phylogeny of the *Algæ*, the possible derivation of the *Rhodophyceæ* from the *Cyanophyceæ* has already been pointed out. Assuming this, there are three series of *Algæ* closely allied in their origin, in each of which evolution has proceeded on more or less divergent lines, thus leading to the development of a number of corresponding forms in the three series. It is not impossible that the *Chlorophyceæ* and the *Phæophyceæ* may also have sprung from the *Cyanophyceæ*, not, like the *Rhodophyceæ*, from the higher forms, but from the lower. But, if the *Cyanophyceæ* be regarded, not as primitive, but as degenerate forms—and for this view there are good grounds—then the simpler *Chlorophyceæ* are probably to be regarded as the forms from which the others have been derived.

Literature of Algæ.—Special papers referred to: Cohn, *Beiträge zur Physiologie der Phycochromaceen*, 1867; Berthold, "Die Bangiaceen," in *Fauna und Flora des Golfes von Neapel*, 1882; Zopf, *Zur Morphologie der Spaltpflanzen*, Leipsic, 1882; Hansgirg, *Physiologische und Algologische Studien*, Prague, 1887. Of general works consult—Harvey, *Phycologia Britannica;* Cooke, *British Freshwater Algæ*, London, 1882; Thuret and Bornet, *Notes Algologiques*, i., ii., 1882-86, and *Études Phycologiques*, 1878; Falkenberg, "Algen," in Schenk's *Handbuch der Botanik*, ii., Breslau, 1881-84; Hauck, "Die Meeresalgen," in Rabenhorst's *Kryptogamen-Flora*, 2d ed., Leipsic, 1885; Goebel, *Outlines of Classification and Special Morphology*, Oxford, 1886. These works contain references to all the more important isolated papers on the *Algæ*.

CLASS II. FUNGI.—In view of the description of these plants given in the article FUNGUS (*q.v.*), it is unnecessary to define them here further than as Thallophytes which are devoid of chlorophyll.

The classification followed here differs in detail from that given in the previous article. It is as follows:

Sub-Class I. **Myxomycetes.**
" II. **Schizomycetes.**
" III. **Phycomycetes.**

a. Zygomycetes.	*b. Oomycetes.*
Order 1. *Chytridiaceæ.*	Order 1. *Ancylisteæ.*
" 2. *Mucorini.*	" 2. *Peronosporeæ.*
" 3. *Entomophthoreæ.*	" 3. *Saprolegnieæ.*
" 4. *Ustilagineæ.*	

" IV. **Ascomycetes.**
Order 1. *Gymnoasceæ.* Order 2. *Pyrenomycetes.*
Order 3. *Discomycetes.*
" V. **Æcidiomycetes.**
Order 1. *Uredineæ.*
" VI. **Basidiomycetes.**
Order 1. *Tremelliai.* Order 2. *Hymenomycetes.*
Order 3. *Gasteromycetes.*

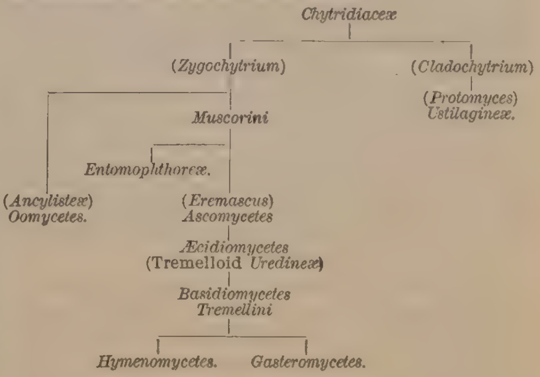
The chief points of difference between this classification and that given in the article FUNGUS, besides the introduction of some additional orders, are the division of the *Phycomycetes* into *Zygomycetes* and *Oomycetes*, the removal of the *Ustilagineæ* from the *Uredineæ* to the *Phycomycetes*, and the inclusion of the *Erysipheæ* and *Tuberaceæ* in the *Pyrenomycetes*, this order being considered as containing all the *Ascomycetes* which have well-developed, but more or less completely closed, apothecia (perithecia),—in a word, all *Ascomycetes* which are neither *Gymnoasceæ* nor *Discomycetes*. The division of the *Phycomycetes* into *Zygomycetes* and *Oomycetes* is necessary in order to distinguish those forms which are isogamous, and in which the sexual process is one of conjugation (see REPRODUCTION), from those which are oogamous, and in which the sexual process is one of fertilization, the former constituting the group *Zygomycetes*, the latter the group *Oomycetes*. The change in position of the *Ustilagineæ*, is made in accordance with the views of recent writers, such as De Bary and Brefeld, the *Ustilagineæ* being regarded as sexually degenerate *Zygomycetes*.

A brief description of the newly introduced orders, namely, the *Chytridiaceæ*, the *Entomophthoreæ*, the *Ancylisteæ*, and the *Gymnoascéæ*, may be given. The *Chytridiaceæ* are extremely simple *Fungi*, consisting in some forms of a single spherical cell and in others of a small mycelium. The *Entomophthoreæ* have a well-developed mycelium, which, unlike that of most *Phycomycetes*, is septate. The *Ancylisteæ* are merely the simplest forms of the *Oomycetes*. The *Gymnoasceæ* are characterized by the simple structure of their fructification, the asci (or, in some cases, the single ascus) not being surrounded by an investment of sterile tissue. This group includes typical forms, such as *Gymnoascus* and *Eremascus*, as well as aberrant forms, such as *Exoascus*, *Saccharomyces*, etc.

Mutual Affinities and Phylogeny of Sub-Classes of Fungi.

The *Myxomycetes* and the *Schizomycetes* are so peculiar that they cannot be connected in any way with the other sub-classes of *Fungi*. Beginning, then, with the *Zygomycetes* there can be no doubt that the *Chytridiaceæ* are closely connected with the *Mucorini* by such forms as *Polyphagus* and *Zygochytrium*, and with the *Ancylisteæ* among the *Oomycetes*. On the other hand, they are connected with the *Ustilagineæ* (especially *Protomyces*) by *Cladochytrium*. The *Entomophthoreæ* seem to be most nearly related to the *Mucorini*. The *Ancylisteæ* are closely related to the *Peronosporeæ* (especially *Pythium*), and these again to the *Saprolegnieæ*. Coming now to the *Ascomycetes*, there is an obvious similarity between the simpler *Gymnoasceæ* and the *Mucorini*. Thus in *Eremascus* the sexual organs are quite similar, and the sexual process is one of conjugation, as in the *Mucorini;* but there is this difference, that the product of the sexual process in *Eremascus* is an ascus, whereas in the *Mucorini* it is a zygospore (see REPRODUCTION). Those *Ascomycetes* which, like *Pyronema*, have differentiated sexual organs, show some resemblance to the *Oomycetes*. The *Uredineæ* appear to be closely connected with the *Ascomycetes* on the one hand, the æcidium being homologous with the apothecium, and on the other hand with the *Tremellini* among the *Basidiomycetes*, through the Tremelloid *Uredineæ* (*Leptopuccinieæ*), which have lost their æcidia, possessing only asexually-produced spores (teleutospores). The *Hymenomycetes* and the *Gasteromycetes* appear to form two parallel series starting from the *Tremellini*.

In attempting to express these relations in terms of phylogeny, the first question which arises is as to whether or not the *Chytridiaceæ* are to be taken as the primitive forms. It is possible to regard them, not as primitive forms, but as degraded *Mucorini*, their degradation being due to their aquatic habit; but there are no conclusive grounds for this assumption. Then there is the question as to the origin of the *Ascomycetes*. De Bary inclines to the opinion that they are derived from the *Oomycetes* (especially *Peronospora*), on account of the similarity of the sexual organs of such *Ascomycetes* as *Podosphæra* to those of the *Peronosporeæ*. But how, on this view, is the development of *Ascomycetes* with similar sexual organs to be accounted for? It seems more reasonable to trace the *Ascomycetes* back through *Eremascus* to the *Mucorini*, and to assume that the differentiation of the sexual organs arose in the Ascomycetous series. The following scheme expresses the phylogeny of the *Fungi* as suggested in the foregoing remarks.



Affinities of Fungi with Algæ.

With the exception of the *Basidiomycetes*, the sub-classes of *Fungi* present resemblances to various forms of *Algæ*, as might be expected, for the *Fungi* must have sprung from the *Algæ*. The *Myxomycetes* resemble the *Hydrodictyeæ*, in that the body (plasmodium) is a cœnobium, formed by the aggregation of originally separate cells. The similarity of the *Schizomycetes* to the *Cyanophyceæ* has been already mentioned (p. 137). The *Phycomycetes* resemble the *Siphoneæ* in their typically unseptate multinucleate structure; but the *Mucorini* approach the Conjugate *Algæ*, and the *Oomycetes* the oogamous *Siphoneæ*, in the sexual process. The simpler *Chytridiaceæ* closely resemble the *Protococcaceæ* in their general form, as also in the production of ciliated zoospores. The *Ascomycetes*, especially those in which male cells (spermatia) are formed, and probably also the *Æcidiomycetes*, resemble the *Rhodophyceæ* in many important features. In both groups the female organ contains no distinctly differentiated female cell (oosphere); and the effect of fertilization is to cause the female organ to grow into a sporogenous fructification (apothecium, cystocarp), which constitutes the asexual generation or sporophyte in the life-history.

With regard to the derivation of the *Fungi* from the *Algæ*, it appears that there are at least two distinct origins. The *Schizomycetes* doubtless arose from the *Cyanophyceæ;* but, as pointed out above, the *Schizomycetes* cannot be regarded as having given rise to higher forms of *Fungi*. These sprang independently from the *Algæ;* and probably the

Chytridiaceæ were derived from the *Protococcaceæ;* and from the *Chytridiaceæ* the higher forms were developed as indicated in the above sketch of the phylogeny of the *Fungi,* the evolution of the *Fungi* proceeding along much the same lines as that of the *Algæ,* and thus giving rise to forms which have their representatives in the *Algæ,* and terminating in the *Basidiomycetes,* which are all together and peculiarly Fungal. The origin of the *Chytridiaceæ* from the *Protococcaceæ* is suggested by the fact that many of the latter are "endophytic:" that is they inhabit the tissues of higher plants; and the *Chytridiaceæ* may be regarded as *Protococcaceæ,* which have become truly parasitic, and have consequently lost their chlorophyll.

Additional Literature to Fungi.—De Bary and Woronin, *Beiträge zur Morphologie und Physiologie der Pilze,* 4th and 5th series, 1881–82; Brefeld, *Untersuchungen,* parts v.–vii., 1883–88; De Bary, *Comparative Morphology and Biology of the Fungi,* Oxford, 1887.

SUBSIDIARY GROUP, LICHENS.—As pointed out in the article FUNGUS, a Lichen is a compound organism consisting of a *Fungus* and an *Alga* living symbiotically. In that article only those Lichens are considered in which the *Fungus* belongs to the *Ascomycetes;* but Lichens are now known in which the *Fungus* belongs to the *Basidiomycetes.*

The Lichens may be classified as follows:

- *Ascolichenes* (Ascomycetous Lichens).
  1. *Discolichenes* (Discomycetous Lichens).
  2. *Pyrenolichenes* (Pyrenomycetous Lichens).
- *Basidiolichenes* (Basidiomycetous Lichens).
  1. *Hymenolichenes* (Hymenomycetous Lichens).
  2. *Gasterolichenes* (Gasteromycetous Lichens).

Literature.—Masse, "On Gasterolichenes," in *Phil. Trans.,* vol. clxxviii., 1887.

SUB-KINGDOM II. BRYOPHYTA (*Muscineæ*).

The *Bryophyta* may be characterized as plants which present a definite alternation of generations, the plant being the gametophyte and the fructification or sporogonium the sporophyte. The sporophyte is not independent, but remains permanently attached to the gametophyte. The shoot of the gametophyte is sometimes thalloid; but more frequently it is differentiated into stem and leaf. The shoot of the sporophyte is not differentiated into stem and leaf, though there is in some cases an indication of such differentiation. The gametophyte commonly reproduces its like by means of gemmæ; the female organ is an archegonium. The *Bryophyta* are divided into two classes—the HEPATICÆ or LIVERWORTS and the MUSCI or MOSSES. (For details see MUSCINEÆ).

Mutual Affinities and Phylogeny of Mosses and Liverworts.

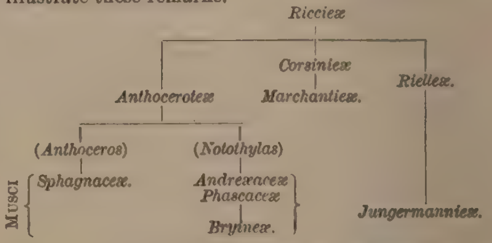
In consequence of the well-marked alteration of generations in these classes, it is essential to trace their resemblances in both generations.

a. Gametophyte (plant).—The higher Liverworts (foliose *Jungermannieæ*) resemble the Mosses in that the shoot is differentiated into stem and leaf; but there is this general difference, that the shoot of these Liverworts has dorsiventral symmetry, whereas that of the Mosses has radial symmetry. The connecting form is afforded by *Haplomitrium,* which alone among the foliose Liverworts has radial symmetry.

b. Sporophyte (sporogonium).—The main differences between the sporogonium of the Liverworts and that of the Mosses are these: the structure of the sporogonium is simpler in the Liverworts than it is in the Mosses; in the former it usually has no columella and produces elaters, whereas in the latter a columella is always present, and there are no elaters. In the Liverworts the sporogonium remains enclosed in the enlarged venter of the archegonium (calyptra) until the spores are ripe, but in most Mosses the developing sporogonium bursts the calyptra at an early stage. A connecting form is afforded by the sporogonium of *Anthoceros* (Liverwort), which has a columella and bears stomata like the sporogonia of the Mosses, and in which the elaters are rudimentary. *Sphagnum* and *Archidium* among Mosses resemble the Liverworts in that the sporogonium is enclosed in the calyptra until near maturity.

Although there are so many points of resemblance between them, there is no evidence to show that the Mosses and Liverworts form one continuous series. This might perhaps be assumed if the gametophyte alone were considered; but it cannot when the sporophyte is taken to account as well. The more important features in the comparative morphology of the sporophyte are as follows. Taking first the Liverworts, in the *Riccieæ* proper (*Riccia, Oxymitra*) both the epibasal and hypobasal halves of the oospore (fertilized female cell) form sporogenous tissue. In the allied *Corsinieæ,* the *Marchantieæ,* and the *Anthoceroteæ* the epibasal half alone gives rise to sporogenous tissue, the hypobasal half forming an organ of absorption and attachment which is the *true foot.* In the *Jungermannieæ,* likewise, the sporogenous tissue is developed entirely from the epibasal half of the oospore, which also gives rise to the seta or stalk of the sporogonium; but the hypobasal half is aborted and gives rise to only a rudimentary foot; in some foliose forms a *false foot* is formed by a dilatation of the base of the seta. In the Mosses there is not in any family such a simple sporophyte as that of the *Riccieæ* among the Liverworts; but there are forms which present the same morphological difference as that which in the Liverworts distinguishes the *Marchantieæ* and the *Anthroceroteæ,* on the one hand, from these *Jungermannieæ,* on the other. Thus, among Mosses the *Sphagnaceæ, Andreaceæ,* and *Phascaceæ* have a true foot, whereas in the *Bryineæ* there is a spurious foot at the base of the seta, as in some *Jungermannieæ.* Taking all the foregoing facts into account, it is clear that the *Riccieæ* are the most primitive of existing *Muscineæ,* and it is probably from them that the true Mosses, as well as the other Liverworts, have been derived.

The following phylogeny may be suggested. As regards the Liverworts, there can be no doubt that the *Marchantieæ* are to be traced back through the *Corsinieæ* to the *Riccieæ,* and it is probable that, as Leitgeb points out, the frondose *Jungermannieæ* were derived from the *Corsinieæ* through the *Rielleæ.* With regard to the *Anthoceroteæ,* Leithgeb seems to suggest that they may have been derived through *Notothylas* from the *Jungermannieæ;* but in opposition to this must be set the difference between the two groups as regards the morphology of the foot. Probably the *Anthoceroteæ* arose independently from the *Corsinieæ.* The Mosses are to be traced back to the *Anthoceroteæ,* on account of the general similarity in the structure of the sporogonium. The genus *Anthoceros* shows its special relation to the *Sphagnaceæ* in the development of the sporogenous cells from the amphithecium, whereas the genus *Notothylas* resembles the other Mosses in that the sporogenous cells are developed from the endothecium. The following scheme will serve to illustrate these remarks.



The phylogeny of the *Muscineæ* can be traced with exceptional clearness in both generations. With regard to the gametophyte, it must be remembered (see MUSCINEÆ) that at its first development from the spore it is a *protonema,* which is either filamentous, as usually in Mosses, or a flattened expansion, as generally in Liverworts, the shoot which bears the sexual organs being a secondary development on the protonema. Both these forms of protonema bear a striking resemblance to various Confervoid *Chlorophyceæ,* and there can be little doubt that it is from this group that the *Muscineæ* have arisen. This view is supported by the close resemblance of the simple sporophyte of *Riccia* among the *Muscineæ* to that of *Coleochæte* among the Confervoid *Chlorphyceæ.* There is, however, this difference, that in *Riccia* the cells resulting from the division of the oospore are differentiated into an external sterile layer, forming the wall of the capsule, and an internal mass of sporogenous cells, whereas in *Coleochæte* all the cells are sporogenous.

SUB-KINGDOM III. PTERIDOPHYTA
(VASCULAR CRYPTOGAMS.)

In these plants the gametophyte is a filamentous or tuberous, or more commonly a membranous, flattened *prothallium,* exhibiting no differentiation into stem and leaf. The sexual organs are antheridia and archegonia, as in the *Muscineæ.* The sporophyte becomes quite independent of the gametophyte, constituting the plant. The shoot is always differentiated into stem and leaf, and the tissues are highly differentiated.

The sub-kingdom is divided into three classes,—FILICINÆ, EQUISETINÆ, LYCOPODINÆ.

Each of these classes includes two series of forms,—the *homosporous*, in which all the spores are alike, and the *heterosporous*, in which the spores are of two kinds, namely, large spores (*macrospores*) and small spores (*microspores*). On germination the spore of the homosporous forms gives rise to a well-developed prothallium, which becomes quite free from the spore, and usually bears both antheridia (male) and archegonia (female). The spores of the heterosporous forms give rise on germination to comparatively inconspicuous prothallia, which remain connected with the spores, and bear either exclusively male or exclusively female organs. Thus, in the heterosporous forms the gametophyte is represented by a male and a female organism, the former being much the smaller. The male prothallium is always developed from a microspore, the female prothallium from a macrospore (see REPRODUCTION).

CLASS 1. FILICINÆ.—The *Filicinæ* are characterized by having relatively large and few leaves. The spore-bearing or fertile leaves (*sporophylls*) are generally similar to the foliage leaves, and are not aggregated on special shoots, so as to form flowers. The embryo sporophyte has no suspensor; but it has generally (except in *Salvinia*) a primary root.

Series A. **Homosporous Filicinæ.**—This series consists of the sub-class *Filices*, which includes the Ferns. It seems to be certain that all existing Ferns are homosporous, and apparently all the known fossil forms are homosporous also, though it is not impossible that there may have been heterosporous *Filices*. The orders of existing Ferns are arranged in two categories, according to the mode of development of the sporangia.

Leptosporangiate Filices: the sporangium is developed from a single epidermal cell:

Order 1. *Hymenophyllaceæ.*
“ 2. *Cyatheaceæ.*
“ 3. *Polypodiaceæ.*
Order 4. *Gleicheniceæ.*
“ 5. *Schizæaceæ.*
“ 6. *Osmundaceæ.*

Eusporangiate Filices: the sporangium is developed from a group of epidermal cells:

Order 1. *Ophioglossaceæ.*
Order 2. *Marattiaceæ.*

Series B. **Heterosporous Filicinæ.**—As far as is known at present, this series contains the sub-class *Hydropterideæ* or *Rhizocarpæ*. In addition to the various peculiarities connected with their heterospory, its members are characterized by the development of an investment round the clusters of sporangia (*sori*), the whole forming a *sporocarp*. They are all Leptosporangiate.

The *Hydropterideæ* are arranged in two orders, according to the structure of the sporocarp.

Order 1. *Salviniaceæ:* wall of sporocarp formed as a superficial outgrowth of the sporophyll; each sporocarp contains a single sorus either of macrosporangia or of microsporangia (*Salvinia, Azolla*).

Order 2. *Marsileaceæ:* the wall of the sporocarp is formed by a portion of the sporophyll; each sporocarp contains several sori; and each sorus includes both macrosporangia and microsporangia (*Marsilea, Pilularia*).

It is possible that *Isoetes* represents the heterosporous eusporangiate *Filices* (see *infra*).

CLASS 2. EQUISETINÆ.—These plants are characterized by their rudimentary foliage leaves arranged in whorls at the nodes, and by their highly modified sporophylls, which are aggregated together at the ends of shoots, so as to form cone-like flowers. The embryo sporophyte has no suspensor, but a primary root.

Series A. **Homosporous Equisetinæ.**—All the existing forms belong to the series and constitute the order *Equisetaceæ;* they all belong to the genus *Equisetum*. The gametophyte is a green flattened prothallium, like that most commonly found in the *Filices;* but it is much branched, and generally diœcious.

Series B. **Heterosporous Equisetinæ.**—There are no existing heterosporous *Equisetinæ;* it is probable that some fossil plants, such as *Annularia* and *Asterophyllites*, represent the extinct heterosporous forms.

CLASS 3. LYCOPODINÆ.—The *Lycopodinæ* are generally characterized by their small and numerous foliage leaves, which are not arranged in whorls, though they are almost entirely wanting in *Psilotum*. The sporophylls are not highly modified, but they are frequently aggregated at the ends of shoots, so as to form cone-like flowers. So far as the embryology of this class is known at present, the embryo sporophyte has a suspensor, but no primary root.

Series A. **Homosporous Lycopodinæ.**

Order 1. *Lycopodiaceæ:* the sporangia are borne on sporophylls (*Lycopodium, Phylloglossum*).

Order 2. *Psilotaceæ:* the sporangia are borne on the stem (*Psilotum, Tmesipteris*).

Series B. **Heterosporous Lycopodinæ.**

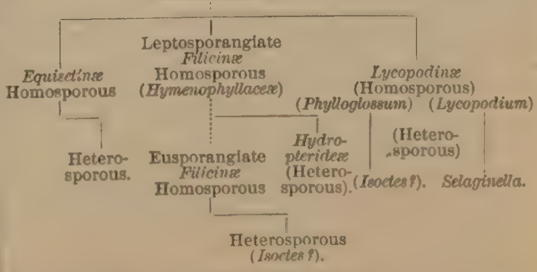
Order 1. *Selaginellaceæ* (*Sellaginella*).

The existing heterosporous *Lycopodinæ* are usually considered to consist of a family, termed the *Ligulatæ*, which includes the two genera *Selaginella* and *Isoetes*. This arrangement is not accepted here, for the reason that *Selaginella* and *Isoetes* have nothing in common beyond the ligule, and the fact that they are both heterosporous vascular cryptogams. It is in fact a question whether or not *Isoetes* should be included in the *Lycopodinæ* at all; for it has few and large leaves, and the embryo sporophyte has no suspensor, but it has a primary root. This being the case, it is impossible to frame any definition of the group *Lycopodinæ* which would apply to all the members, if *Isoetes* be included in it. In many features *Isoetes* resembles the *Felicinæ*, and especially the *Hydropterideæ*. It may be suggested here that *Isoetes* is a representative of the heterosporous eusporangiate *Felicinæ*. The only member of the *Lycopodinæ* which *Isoetes* at all resembles is *Phylloglossum*.

Mutual Affinities and Phylogeny of Pteridophyta.

Beyond the characteristics which they possess in common, and which have caused them to be collected into one class, there are no special points of contact between the three sub-classes of the *Pteridophyta*. The classes have each its own well-marked habit; and it therefore appears probable that they are to be regarded as equivalent branches of the *Pteridophyta*, springing from a common origin, in each of which a differentiation of homosporous and heterosporous forms has taken place. The relation of the homosporous to the heterosporous forms in each class is a point of interest. There is little or nothing to be said on this subject as regards the *Equisetinæ*. But in the *Filicinæ* it appears probable that the simpler heterosporous forms have sprung from the simpler homosporous forms, that is, the *Salviniaceæ* from the *Hymenophyllaceæ;* and in the *Lycopodinæ* that *Selaginella* has sprung from *Lycopodium*. Assuming that *Isoetes* belongs to the *Lycopodinæ*, its nearest ally would appear to be *Phylloglossum;* but this point must remain undecided until the whole life-history, especially the embryogeny, of *Phylloglossum* is known, and its true systematic position thereby fixed.

Various attempts have been made to trace back the sporophyte of the *Pteridophyta* to that of the *Muscineæ*, the points of contact being the *Hymenophyllaceæ* on the one hand and *Anthoceros* on the other; but these attempts cannot be considered to have been successful. The differences between the known forms of sporophyte in the two classes are too great to be explained away on any hypothesis. The case is different with regard to the gametophyte; there are, in fact, many points of resemblance between the prothallium of the *Pteridophyta* and the gametophyte of the *Muscineæ*. As Goebel and Bower have pointed out, the prothallium of some species of *Trichomanes* is a branched filamentous structure, closely resembling Moss protonema; and in most ferns, as also in *Equisetum* and *Lycopodium*, the prothallium is at first filamentous. The filamentous prothallium gives rise to one or more flattened expansions, on which the sexual organs, or at least the archegonia, are developed (*archegoniophores*). Thus there are indications in the gametophyte of many *Pteridophyta* of that distinction of protonema and sexual shoot which is so characteristic of the gametophyte of the *Muscineæ*. But this remarkable correspondence in the gametophyte does not warrant the conclusion that the *Pteridophyta* have sprung from the *Muscineæ*. It rather indicates that they are groups having a common origin in the Confervoid *Chlorophyceæ*, but diverging from the first in the relation of the sporophyte to the gametophyte, so that, whereas in the *Muscineæ* the sporophyte remains attached to the gametophyte throughout its whole existence, in the *Pteridophyta* the sporophyte develops as an independent organism. There can be little doubt that in the primitive *Pteridophyta* the two generations resembled each other, and that, as evolution proceeded, they became more and more widely dissimilar, the gametophyte losing, the sporophyte gaining, in both morphological and histological differentiation. An indication of this



(*Chlorophyceæ*)
Leptosporangiate *Filicinæ* Homosporous (*Hymenophyllaceæ*)
Equisetinæ Homosporous
Lycopodinæ (Homosporous)
(*Phylloglossum*)
(*Lycopodium*)
Hetero-sporous.
Eusporangiate *Filicinæ* Homosporous
Hydropterideæ (Heterosporous).
(Hetero-sporous)
(*Isoetes?*).
Selaginella.
Heterosporous (*Isoetes?*).

is still afforded by the general resemblance of the sporophyte of *Phylloglossum* to the gametophyte of *Lycopodium cernuum* as described by Treub, and of the sporophyte of *Lycopodium Phlegmaria* to its gametophyte (Treub). It will probably be found, when material is obtained for investigating it, that the sporophyte and the gametophyte of *Phylloglossum* are very similar.

The phylogeny of the *Pteridophyta*, as suggested in the foregoing remarks, is indicated in the table on page 141.

Literature of Pteridophyta.—Affinities and phylogeny: Prantl, *Untersuchungen zur Morphologie der Gefässkryptogamen*, i.–ii., Leipsic, 1875–1881; Goebel, *Annales du Jardin Botanique de Buitenzorg*, vii., 1887; Bower, "On some Normal and Abnormal Developments of the Oophyte of *Trichomanes*," in *Annals of Botany*, vol. i., 1888; Id., On the Morphology of *Phylloglossum Drummondii*, in *Phil. Trans.*, part II., 1885; Treub, "Recherches sur les Lycopodiacées," in *Ann. du Jardin Botanique de Buitenzorg*, iii.–iv., 1884–1886; Id., *Annals of Botany*, i., 1888; Kny, "Die Entwickelung der Parkeriaceen," in *Nova Acta d. k. Leop. Akad.*, xxxvii., 1875. For general works, see Goebel, *Outlines of Classification and Special Morphology*, Oxford, 1887; Sadebeck, "Die Gefässkryptogamen," in Schenk's *Handbuch der Botanik*, i., 1879.

SUB-KINGDOM IV. PHANEROGAMIA.

These plants are commonly known as "flowering plants"; but they are more correctly designated "seed-bearing plants," or *Spermaphyta*, for the production of a seed is the one feature which distinguishes the members of this sub-kingdom from those of the other sub-kingdoms.

There is a definite alternation of generations in the life-history of these plants, but it is obscured by the extreme reduction which the gametophyte has undergone (see REPRODUCTION). The sporophyte is the plant; a suspensor is formed in its embroyogeny; and it is heterosporous. The sporophylls are aggregated on special shoots, frequently with other floral leaves (bracteoles, perianth leaves), to form flowers. The two kinds of sporangia are in all cases borne on distinct sporophylls. In the micro-sporangium there are numerous fertile sporogenous cells, each of which produces four microspores; in the macrosporangium there are generally but few sporogenous cells, of which only one is usually fertile, and this one produces a single macrospore without division. The microspores are set free from the sporangium producing them, whereas the macrospore is not. It is this last peculiarity which determines the formation of the seed.

In the above account of the asexual reproductive organs of the *Phanerogamia*, the terms employed are those which are applied in the case of the heterosporous *Pteridophyta*; the advantage gained by the use of these terms is that the true homologies of the reproductive organs in the two sub-kingdoms are kept in view. The relation between these terms and those more commonly in use is as follows: stamen = leaf bearing microsporangia (microsporophyll); carpel = leaf bearing macrosporangia (macrosporophyll); pollen-sac = microsporangium; anther = sorus of microsporangia; ovule (nucellus) = macrosporangium; pollen-grain = microspore; embryo sac = macrospore. Stamens and carpels are commonly borne by the same individual and in the same flower; but in many cases they are confined to distinct individuals (*diœcious*) or to distinct flowers (*diclinous*) on the same individual.

Inasmuch as these plants are heterosporous, the sexual generation is represented by male and female gametophytes. The male gametophyte, formed by the germination of the microspore (pollen-grain), consists of two or sometimes three or four cells, one of which becomes the male organ (pollen tube = antheridium of other sub-kingdoms), while the rest have nothing to do with reproduction, but constitute the rudimentary vegetative portion of the prothallium. The female gametophyte, commonly known as the *endosperm* (= female prothallium), is formed in the interior of the macrospore or embryo sac, and usually does not come at all into relation with the exterior. From certain cells of this endosperm one or more female organs are formed, which are equivalent to, and in some Phanerogams closely resemble, the archegonia of the *Pteridophyta*; each of these female organs possesses, as its essential constituent, the female cell (oosphere, ovum).

The process of fertilization (see REPRODUCTION) depends upon the pollen-grains being brought near to the ovules, so that, when the pollen-grains germinate, the pollen tubes may be able, in the course of their growth, to come into close relation with the female cells which the ovules contain. In many cases the transference of the pollen-grains is effected by the wind; the plants in which this is the case are characterized by their inconspicuous flowers, and are termed *anemophilous*. In other cases the transference is effected by means of insects; the plants in which this is the case are termed *entomophilous*, and are characterized by their conspicuous flowers, in which the perianth leaves are highly developed and brightly colored, to attract the visits of insects,—an end which is further attained by the secretion of scented volatile oils and of sugary liquid (nectar). It is the conspicuous flowers of these entomophilous *Phanerogamia* which have earned for the whole group the designation of "flowering plants," which, however, is by no means generally applicable.

The *Phanerogamia* are divided into two classes,—the GYMNOSPERMÆ and the ANGIOSPERMÆ.

CLASS I. GYMNOSPERMÆ.—The carpels are sometimes absent, and, when present, they do not form an ovary; hence the ovules are naked. There is no stigma, consequently the pollen-grain comes into direct contact with the ovule. The whole of the female prothallium is formed in the embryo sac before fertilization. The female organ is in most cases a fully developed archegonium. The embryo is developed from a portion only of the fertilized female cell or oospore (*meroblastic embryogeny*); frequently several embryos are developed from one oospore (*polyembryony*). The flowers are diœcious or diclinous.

This class consists of the following orders:

Order 1. *Cycadaceæ:* characterized generally by the unbranched stem and by the large branched leaves. The order includes nine genera: *Cycas, Dioon, Ceratozamia, Zamia, Macrozamia, Encephalartos, Stangeria, Bowenia*, and *Microcycas*. The genus *Cycas* is peculiar, in that the carpels are not borne on special shoots, so as to form flowers, but on the main shoot, in the same way as the foliage leaves. The stamens of *Cycas*, as also both the stamens and carpels in the other genera, are highly modified sporophylls which are borne on special shoots forming cone-like flowers.

Order 2. *Coniferæ:* characterized by the much-branched stem, and by the very numerous, small, unbranched leaves. The staminal flowers are generally cone-like. This order includes the Pines, Firs, Larches, Yews, Cypresses, etc., arranged in the following families:

Series A. **Pinoideæ**: the carpellary flowers are cones:
Fam. 1. *Abietineæ.*
" 2. *Araucarieæ.*
Fam. 3. *Cupressineæ.*
" 4. *Taxodineæ.*

Series B. **Taxoideæ**: the capillary flowers are not cones:
Fam. 1. *Taxineæ.*
Fam. 2. *Podocarpeæ.*

Order 3. *Gnetaceæ:* habit various; the flowers are not cones, and have a perianth. This order includes the three genera *Ephedra, Gnetum*, and *Welwitschia*. In *Gnetum* and *Welwitschia* the female organ (archegonium) is reduced to a single cell, the oosphere.

Mutual Affinities and Phylogeny of Gymnospermæ.

There is but little resemblance between the *Cycadaceæ* and the other two orders. *Gingko* or *Salisburia*, a remarkable genus which is usually placed in the *Taxineæ*, though it is in many respects peculiar, resembles the *Cycadaceæ* in the structure of the archegonium, in the fleshy character assumed by the outer portion of the seed-coat, and in the fact that the development of the embryo does not begin until after the seed has been shed. Probably the fossil plants known as the *Cordaitaceæ* may be regarded as a group intermediate between the *Cycadaceæ* and the *Coniferæ*. The *Coniferæ* and the *Gnetaceæ* are more closely allied, so much so in fact that the latter have been regarded by various writers as a family of the *Coniferæ*. The structure of the flowers in *Ephedra* is very similar to that in *Taxus*.

The connection of the Gymnosperms with the *Pteridophyta* is undoubted. The development of the microsporangium in the Gymnosperms is the same as that of the sporangium of *Lycopodium*. The development of the macrosporangium presents in most cases the characteristic Phanerogamic features; but in certain cases (*Ceratozamia longifolia, Cupressus sempervirens, Cullitris quadrivalvis*) there is a mass of sporogenous cells, as in the sporangia of the *Pteridophyta*, though only one of these cells is fertile, and it produces a single macrospore without division. In fact, there is a marked general resemblance in the development of the macrosporangium between these species and *Isoetes*. Another point of importance is the fact that, although the female prothallium (endosperm) is under ordinary conditions entirely and permanently enclosed in the macrospore (embryo sac)—a feature which is characteristic of the *Phanerogamia*—yet in the *Cycadaceæ*, if the first formed archegonia are not fertilized, the prothallium resumes its growth and bursts the macrospore, coming to the surface of the ovule and turning green in consequence of exposure to light. Taking into consideration their general habit and the peculiarities in the development of their sporangia, it appears that the *Cycadaceæ* find in the Eusporangiate *Filices* their nearest allies among the *Pteridophyta*. This suggestion presupposes the existence of heterosporous *Eusporangiata*, although all the known forms are homosporus. But this difficulty will be met, if, as suggested above, it turns out that *Isoetes* really belongs to the Eusporangiate *Filices*. The *Coniferæ* resemble more nearly the *Lycopodinæ*, such as *Lycopodium* and *Selaginella*, in their general habit and in the cone-like form of their flowers. However, the position of the pollen-sacs on the under surface of the peltate sporophyll is a feature which connects them with the *Equisetinæ*; but, on the other hand, the lingular outgrowth on the upper surface of the macrosporophyll in *Araucaria*, which in the *Abietineæ* becomes the large ovuliferous scale, is another point of resemblance to *Selaginella* and *Isoetes*. In view of these resemblances to the *Lycopodinæ* and the *Equisetinæ*, it is hardly possible to trace back the *Coniferæ* to either of these groups: it is more probable that they sprang from forms of *Pteridophyta* intermediate in character between the *Lycopodinæ* and the *Equisetinæ*. The mutual relations and the phylogeny of the three genera of *Gnetaceæ* cannot at present be determined with any degree of probability. The one point which affords any clue is the resemblance in general structure between the flowers of *Gnetum* and those of the *Taxineæ*. The flower of *Welwitschia*, more than that of any other Gymnosperm, resembles that of an Angiosperm, especially in the fact that the staminal flower contains a rudimentary ovule.

Class II. Angiospermæ.—The carpel or carpels form an ovary in which the ovules are enclosed. A portion of the carpel forms a stigma, which receives the pollen-grains. The pollen-grains germinate on the stigma, and therefore do not come into direct relation with the ovules. A part only of the female prothallium (*primary endosperm*) is formed before fertilization, the remainder (*secondary endosperm*) after fertilization. The female organ is a reduced archegonium, consisting merely of the female cell (oosphere). The general occurrence of both macrosporophylls and microsporophylls in the same flower is a characteristic feature of this group, as is also the whorled arrangement of the floral leaves.

The *Angiospermæ* are divided into two sub-classes,—the *Monocotyledons* and the *Dicotyledons*, according to the number of the primary leaves or cotyledons of the embryo; hence, in the former sub-class the first leaves are alternate, in the latter opposite. In the Monocotyledons, with a few exceptions, the growing-point of the embryonic stem is lateral; in the Dicotyledons it is always terminal. There are other distinguishing features, such as the parallel venation of the leaves of Monocotyledons and the reticulate venation in Dicotyledons; but they are not sufficiently constant to be of much taxonomic value.

The **Monocotyledons** may be conveniently arranged in the following series:

Series 1. *Nudifloræ:* usually diclinous or diœcious; perianth wanting or rudimentary. This series includes the *Spadicifloreæ* (Aroids, Palms, *Naiadeæ*) and the *Glumifloræ* (Grasses, Sedges).

Series 2. *Petaloideæ:* usually monoclinous; perianth present, and usually well-developed and colored. This series includes the Lilies, Orchids, Irises, etc.

The **Dicotyledons** are usually classified as follows:

Series 1. *Monochlamydeæ:* usually diclinous or diœcious; perianth absent or simple.

Series 2. *Polypetalæ:* usually monoclinous; perianth usually consists of calyx and colored corolla, the petals being free.

Series 3. *Gamopetalæ:* usually monoclinous; perianth usually consists of calyx and colored corolla, the petals being coherent.

Phylogeny of the Angiosperma.

There can be no doubt that the *Angiospermæ* have been derived from the *Pteridophyta*; but it is a question whether they have had an independent origin from that group or whether they are to be traced back to it through the Gymnosperms. In view of the wide gulf which separates the Angiosperms from even the highest *Pteridophyta*, and of the affinities of the Gymnosperms to the *Pteridophyta* on the one hand and to the Angiosperms on the other, the latter suggestion would appear to be the more probable.

Although the Monocotyledons and the Dicotyledons have so many features in common, it is probable that they have not had the same origin. The Gymnospermous forms to which the Dicotyledons are most nearly allied are the *Coniferæ*, and *Gnetum* among the *Gnetaceæ*. The marked Angiospermous characters of *Gnetum*, and its general similarity in habit to a Dicotyledonous plant, afford some ground for regarding this genus as the starting point of the Dicotyledons. But more probably the Dicotyledons are to be traced back to the *Conifereæ*, and the *Gnetaceæ*, to be regarded as a lateral offshoot of the *Coniferæ*, with an Angiospermous tendency, but not leading on to higher forms. The Gymnosperms which most resemble the Monocotyledons are the *Cycadaceæ*; and, if it be assumed that the Angiosperms have sprung from the Gymnosperms, it is to this order of the latter class that the Monocotyledons are to be traced. The Monocotyledons in which this resemblance is most conspicuous are those, such as the Aroids and Palms, which belong to the series *Nudifloræ*.

Literature.—On the *Phanerogamia*, see Goebel, *Outlines of Classification and Special Morphology*, Oxford, 1887; Le Maout and Decaisne, *Traité de Botanique* (English ed. by Hooker, 1868); and Engler and Prantl, *Die Pflanzenfamilien*, Leipsic (in course of publication).

On the phylogeny of plants, see Nägeli, *Theorie d. Abstammungslehre*, Munich, 1884; and Saporta and Marion, *L'Évolution du Règne Végétal* (Int. Sci. Series, vols. xxxix. and lii.), Paris, 1881–85. Descriptions of the numerous natural orders will be found in the various text-books which treat of systematic botany, as well as in the above. (S. H. V.)

VEGETABLE MARROW. See Gourd and Horticulture, vol. xii. p. 294.

VEGETIUS, Flavius Renatus, the compiler of a treatise on the art of war, dedicated to Valentinian II. (375–392). Nothing is known of his life save that in MSS. he is called *vir illustris* and also *comes*. His sources, according to his own statement, were Cato, Cornelius Celsus, Frontinus, Paternus, and the imperial constitutions of Augustus, Trajan, and Hadrian. The book, which is a poor compilation, has to be used with great caution. The first edition appeared at Utrecht in 1473; the latest is that of Lang (Leipsic, 1869). The book has been often translated; an English version through the French was published by Caxton in 1489.

VEGLIA (Slavonic, *Krk*), an island in the Gulf of Quarnero, Adriatic Sea, belonging to the Austrian district of Istria, is separated from the mainland by the narrow channel of Morlacca or Maltempo and from the island of Cherso on the southwest by that of Mezzo. It is 24 miles long and about 14 miles across at its widest part. The surface is mostly rugged and mountainous; but the central, southern, and western districts are fertile, producing wine, grain, oil, timber, and various kinds of fruit, besides pasturage for numerous live-stock. Silk, marble, and salt are also produced; and fishing is carried on along the coast. In 1880 the island contained 18,089 inhabitants; the capital is Veglia, a town on the southwest side, with 1580 inhabitants and a good harbor.

VEHMIC COURTS. See Fehmic Courts.

VEII. See Etruria, vol. viii. p. 557.

VELAZQUEZ, Diego de Silva (1599–1660), the head of the Spanish school of painting and one of the mightiest painters the world has known, was born in Seville early in June, 1599, the year in which Van Dyck also first saw the light at Antwerp. His European fame is of comparatively recent origin, dating from the first quarter of the 19th century. Till then his pictures had lain immured in the palaces and museum of Madrid; and from want of popular appreciation they had to a large extent escaped the rapacity of the French marshals during the Peninsular War. In 1828 Sir David Wilkie [1] wrote from Madrid that he felt himself in the presence of a new power in art as he looked at the works of Velazquez, and at the same time found a wonderful affinity between this master and the English school of portrait painters, being specially reminded of the firm, square touch of Raeburn. He was struck by the sense of modernness of impression, of direct contact with nature, and of vital force which pervaded all the work of Velazquez, in landscape as well as in portraiture. Time and criticism have now fully established his reputation as one of the most consummate of painters, and accordingly Mr. Ruskin says of him that "everything Velazquez does may be taken as absolutely right by the student." At the present day his marvellous technique and strong individuality have given him a power in European art such as is exercised by no other of the old masters. Acquainted with all the Italian schools, the friend of the foremost painters of his day, he was strong enough to withstand every external influence and to work out for himself the development of his own nature and his own principles of art. A realist of the realists, he painted only what he saw; consequently his imagination seems limited. His religious conceptions are of the earth earthy, although some of his works, such as the Crucifixion and the Scourging, are characterized by an intensity of pathos in which he ranks second to no painter. His men and women seem to breathe; his horses are full of action and his dogs of life; so quick and close is his grasp of his subject. England was the first nation to recognize his extraordinary merit, and it owns by far the largest share of his works outside of Spain.[1] But Velazquez can only be seen in all his power in the gallery of the Prado at Madrid, where over sixty of his works are preserved, including historical, mythological, and religious subjects, as well as landscapes and portraits. It is hardly creditable to the patriotism of Seville, his native town, that no example of his work is to be seen in the gallery of that city. Seville was then in the height of its prosperity, "the pearl of Spain," carrying on a great trade with the New World, and was also a vigorous centre of literature and art. For more than a hundred years it had fostered a native school of painting which ranked high in the Peninsula, and it reckoned among its citizens many whose names are prominent in Spanish literature.

---

[1] See Cunningham's *Life*, vol. ii.

Velazquez was the son of Rodriguez de Silva, a lawyer in Seville, descended from a noble Portuguese family, and was baptized on 6th June, 1599. Following a common Spanish usage, he is known by his mother's name, Velazquez. There has been considerable diversity of opinion as to his full name, but he was known to his contemporaries as Diego de Silva Velazquez, and signed his name thus. He was educated, says Palomino, by his parents in the fear of God, and was intended for a learned profession, for which he received a good training in languages and philosophy. But the bent of the boy was towards art, and he was placed under the elder Herrera, a vigorous painter who disregarded the Italian influence of the early Seville school. From his works in Seville we can see that Herrera was a bold and effective painter; but he was at the same time a man of unruly temper and his pupils could seldom stay long with him. Velazquez remained but one year, long enough, however, to influence his life. It was from Herrera that he learned to use long brushes, or, as Mr. J. E. Hodgson, R.A., suggests, brushes with long bristles, by means of which his colors seem to be floated on the canvas by a light, fluent touch, the envy and despair of his successors. From Herrera's studio Velazquez betook himself to a very different master, the learned and pedantic Pacheco, the author of a heavy book on painting, and, as we see by his works at Madrid, a dull, commonplace painter. In this school he remained for five years, studying proportion and perspective, and seeing all that was best in the literary and artistic circles of Seville. Here also—and this may explain much—he fell in love with his master's daughter Juana, whom he married in 1618 with the hearty approval of Pacheco, who praises his hand and heart, claiming at the same time all the credit of having been his master. He must, however, have found Velazquez a wayward pupil; for, instead of looking to Raphael, according to orders, the young painter set himself to copying the commonest things about him,—earthenware jars of the country people, birds, fish, fruit, and flowers of the market-place. To paint well and thoroughly what he saw, to model with his brush, and to color under the influence of light and shade were for him the vital purpose, the first lesson, in his art. It was with deliberate purpose that Velazquez painted these *bodegones* (tavern-pieces), as they were called; for we are told that he said he would rather be the first painter of common things than the second in higher art. Carrying out this idea still further, Velazquez felt that to master the subtlety of the human face he must make this a special study, and he accordingly engaged a peasant lad to be his servant and model, making innumerable studies in charcoal and chalk, and catching his every expression. We see this model in the laughing Peasant Boy of the Belvedere Gallery at Vienna. In such work as this, and in his studies by the wayside, Velazquez laid the foundation of his subsequent mastery of expression, of penetration into character, and of rendering the life of his sitter to the quick. He saw the world around him teeming with life and objects of interest to the painter, and he set himself to render these. His manner is as national as that of Cervantes. He lived and died racy of the soil. The position and reputation of Velazquez were now assured at Seville. There his wife bore him two daughters,—all his family so far as is known. The younger died in infancy, while the elder, Francisca, in due time married Bautista del Mazo, a painter, whose large family is probably that which is represented in the important picture of later years in Vienna, the so-called Family of Velazquez. Mr. Curtis, however, is inclined to believe that this picture is by Mazo. In the gallery at Madrid there is at least one portrait of this daughter, painted in these early days at Seville, as also a portrait of Juana his wife, holding a drawing-tablet on her knee. There was formerly in the possession of Lord Dudley another portrait of his wife by Velazquez, painted, perhaps, in the first year of their happy marriage. Of this early Seville manner we have an excellent example in El Aguador (the Water-Carrier) at Apsley House (London). Firm almost to hardness, it displays close study of nature. One can see in it the youthful struggle to portray the effects of light stealing here and there over the prominent features of the face, groping after the effects which the painter was to master later on. The brushwork is bold and broad, and the outlines firmly marked. As is usual with Velazquez at this time, the harmony of colors is red, brown, and yellow, reminding one of Ribera. For sacred subjects we may turn to the Adoration of the Magi at Madrid, dated 1619, and the Adoration of the Shepherds in the London National Gallery, in both of which we have excellent examples of his realism. The peasants offering their gifts of poultry are the hard-featured women of the market-place of Seville, pre-Raphaelite in their uncompromising truthfulness. Thus also in the St. John in the Desert we find his peasant boy transformed into the saint.

But Velazquez was now eager to see more of the world. Madrid, with its fine Titians, held out strong inducements. Accordingly in 1622, fortified with letters of introduction to Fonseca, who held a good position at court, he spent some months there, accompanied only by his servant. Here he painted the portrait of the poet Gongora, a commission from Pacheco, which now hangs in the gallery at Madrid. The impression which Velazquez made in the capital must have been very strong, for in the following year he was summoned to return by Olivares, the all-powerful minister of Philip IV., fifty ducats [gold $113.40] being allowed to defray his expenses. On this occasion he was accompanied by his father-in-law. Next year (1624) he received from the king three hundred ducats [gold $680.40] to pay the cost of the removal of his family to Madrid, which became his home for the remainder of his life. Weak and worthless as a king, Philip had inherited the art-loving propensities of his race, and was proud to be considered a poet and a painter. It is one of the best features of his character that he remained for a period of thirty-six years the faithful and attached friend of Velazquez, whose merit he soon recognized, declaring that no other painter should ever paint his portrait. By his equestrian portrait of the king, painted in 1623, Velazquez secured admission to the royal service with a salary of twenty ducats [gold $45.36] per month, besides medical attendance, lodgings, and payment for the pictures he might paint. The portrait was exhibited on the steps of San Felipe, and was received with enthusiasm, being vaunted by poets, among them Pacheco. It has unfortunately disappeared, having probably perished in one of the numerous fires which occurred in the royal palaces. The Prado, however, has two portraits (Nos. 1070 and 1071) which are most probably studies for this picture. In them the harshness of the Seville period has disappeared and the tones are more delicate. The modelling is firm, recalling that of Antonio Moro, the Dutch portrait-painter of Philip II., who exercised a considerable influence on the Spanish school. In the same year the Prince of Wales (afterwards Charles I.) arrived at the court of Spain. We are told that he sat to Velazquez, but the picture has disappeared.[1] It was during this period also that he painted the hunting-scenes of which examples are to be found in the collections of Sir Richard Wallace, Lord Clarendon, and others, and which served him in the production of the great Boar Hunt of the London National Gallery, painted, however, in the later years of his life,—a magnificent work in spite of some restorations. It was then too that he painted the groups of Court Gallants in their gay costumes, accompanied, as in the Boar Hunt, by their servants and dogs. The splendid Meeting of Artists (as it is absurdly named) in the Louvre was doubtless executed at a later time from studies taken in these early years, for it displays all the qualities of his finer work, space and air being thrown round the figures, which are touched with great mastery and ease.

---

[1] Of the 274 works attributed to Velazquez by Mr. Curtis 121 are in the United Kingdom, while France has but 13, Austria-Hungary 12, Russia 7, and Germany about the same number.

In 1628 Rubens visited Madrid on a diplomatic mission for nine months, and Velazquez was appointed by the king to be his guide among the art treasures of Spain. Rubens was then at the height of his fame, and had undertaken as a commission from Olivares the large pictures which now adorn the great hall in Grosvenor House (London). These months might have been a new turning-point in the career of a weaker man than Velazquez, for Rubens added to his brilliant style as a painter the manner of a fascinating courtier. Rubens had a high opinion of the talent of Velazquez, as is attested by Fuensalida, but he effected no change in the style of the strong Spaniard. He impressed him, however, with the desire to see Italy and the works of her mighty painters. In 1627 the king had given for competition among the painters of Spain the subject of the Expulsion of the Moors. Velazquez bore off the palm; but his picture was destroyed in a fire at the palace in 1734. Palomino, however, decribes it. Philip III. points with his baton to a crowd of men and women driven off under charge of soldiers, while Spain, a majestic female, sits looking calmly on. The triumph of Velazquez was rewarded by his being appointed gentleman usher. To this was shortly afterwards added a daily allowance of twelve reals, the same amount as was allowed to the court barbers, and ninety ducats [gold $204.12] a year for dress, which was also paid to the dwarfs, buffoons, and players about the king's person—truly a curious estimate of talent at the court of Spain. As an extra payment he received (though it was not paid for five years) one hundred ducats [gold $226.80] for the picture of Bacchus, painted in 1629 (No. 485 of the Madrid gallery). The spirit and aim of this work are better understood from its Spanish name, Los Borrachos or Los Bebedores (the Topers), who are paying mock homage to a half-naked ivy-crowned young man seated on a wine barrel. It is like a story by Cervantes, and is brimful of jovial humor. One can easily see in this picture of national manners how Velazquez had reaped the benefit of his close study of peasant life. The painting is firm and solid, and the light and shade are more deftly handled than in former works. Altogether, this production may be taken as the most advanced example of the first style of Velazquez. It is usual to divide his artistic career by his two visits to Italy, his second style following the first visit and his third the second. Roughly speaking, this somewhat arbitrary division may be accepted, though it will not always apply, for, as is usual in the case of many great painters, his styles at times overlap each other. Velazquez rarely signed his pictures, and the royal archives only give the dates of his more important works. Internal evidence and history, as regards his portraits, supply to a certain extent the rest.

In 1629 Philip gave Velazquez permission to carry out his desire of visiting Italy, without loss of salary, making him besides a present of 400 ducats [gold $907.20], to which Olivares added 200 [gold $453.60]. He sailed from Barcelona in August in the company of the marquis De Spinola, the conqueror of Breda, then on his way to take command of the Spanish troops at Milan. It was during this voyage that Velazquez must have heard the details of the surrender of Breda from the lips of the victor, and he must have sketched his fine head, known to us also by the portrait by Van Dyck. But the great picture was not painted till many years later, for Spinola had fallen into disfavor at court. In Venice Velazquez made copies of the Crucifixion and the Last Supper of Tintoretto, which he sent to the king, and in Rome he copied Michelangelo and Raphael, lodging in the Villa Medici till fever compelled him to remove into the city. Here he painted the Forge of Vulcan (No. 1059 of the Madrid gallery), in which Apollo narrates to the astonished Vulcan, a village blacksmith, the news of the infidelity of Venus, while four Cyclops listen to the scandal. The mythological treatment is similar to that of the Bacchus: it is realistic and Spanish to the last degree, giving a picture of the interior of an Andalusian smithy, with Apollo thrown in to make the story tell. The conception is commonplace, yet the impression it produces is undoubted from the vividness of the representation and the power of expression. The modelling of the half-naked figures is excellent. Altogether this picture is much superior to the other work painted at the same time, Joseph's Coat, which now hangs in the Escorial. This work has been much praised—overpraised in the opinion of the present writer—and this opinion is shared by Don Federico de Madrazo, the director of the Madrid museum, who looks on it as one of the weakest of the productions of Velazquez. Both these works are evidently painted from the same models. In looking at these two pictures what stikes one especially is that they betray no trace of the influence of the Italians. Velazquez remained true to himself. At Rome he also painted the two beautiful landscapes of the Gardens of the Medici, now in the Madrid museum, full of sparkle and charm. Landscape as a form of art never had attraction for the Spaniards; but Velazquez here, and in the silvery landscapes painted some years later at Aranjuez, shows how great a master he was in this branch of art. After a visit to Naples in 1631, where he worked with his countryman Ribera, and painted a charming portrait of the infanta Maria, sister of Philip, he returned early in the year to Madrid.

---

[1] In 1847 Mr. John Snare of Reading exhibited a picture which had come from the sale of Lord Fife in 1809, and which he maintained to be the long lost work. This led to much controversy; but the claim was rejected by experts and the picture is said to be now in America.

He then painted the first of many portraits of the young prince Don Baltasar Carlos, the heir to the throne, dignified and lordly even in his childhood, caracolling in the dress of a field-marshal on his prancing steed. Sir Richard Wallace owns a fine example; but the finest in the United Kingdom is the well-known picture at Grosvenor House, a masterly example of the second manner of Velazquez. The color is warm and bright, the workmanship solid and fused like enamel, while light and air pervade every corner. The scene is in the riding-school of the palace, the king and queen looking on from a balcony, while Olivares is in attendance as master of the horse to the prince. Don Baltasar died in 1646, at the age of seventeen, so that judging by his age this picture must have been painted about 1641, two years before the fall of Olivares. This powerful minister was the early and constant patron of the painter. His impassive saturnine face is familiar to us from the many portraits painted by Velazquez, a face which, like his royal master's, seems never to have known a smile, and in which are written pride and disdain. Two must be named of surpassing excellence,—the full length belonging to Mr. Holford (exhibited at Burlington House in 1887), stately and dignified, in which he wears the green cross of Alcantara and holds a wand, the badge of his office as master of the horse; the other the great equestrian portrait of the Madrid gallery (No. 487), in which he is flatteringly represented as a field-marshal in all his pomp during an action. It is difficult to overpraise the excellence of this work, either as regards its dramatic power or its masterly execution. In these portraits Velazquez has well repaid the debt of gratitude which he owed to his first patron, whom he stood by in his fall, thus exposing himself to the risk—and it was not a light one—of incurring the anger of the jealous Philip. The king, however, showed no sign of malice towards his favored painter. Faithful in few things, Philip kept true to Velazquez, whom he visited daily in his studio in the palace, and to whom he stood in many attitudes and costumes, as a huntsman with his dogs, as a warrior in command of his troops, and even on his knees at prayer, wearing ever the same dull uninterested look. His pale face and lack-lustre eye, his fair flowing hair and moustaches curled up to his eyes, and his heavy projecting Austrian lip are known in many a portrait and nowhere more supremely than in the wonderful canvas of the London National Gallery (No. 745), where he seems to live and breathe. Few portraits in the whole range of art will compare with this work, in which the consummate handling of Velazquez is seen at its best, for it is in his late and most perfect manner.[1] From one of the equestrian portraits of the king, painted in 1638, the sculptor Montañas modelled a statue which was cast in bronze by the Florentine sculptor Tacca, and which now stands in the Plaza del Oriente at Madrid, "a solid Velazquez," as it has been well named by Ford. This portrait exists no more; but there is no lack of others, for Velazquez was in constant and close attendance on Philip, accompanying him in his journeys to Aragon in 1642 and 1644, and was doubtless present with him when he entered Lerida as a conqueror. It was then that he painted the great equestrian portrait (No. 1066 of the Madrid gallery) in which the king is represented as a great commander leading his troops,—a rôle which Philip never played except in a theatrical pageant. All is full of animation except the stolid face of the king. It hangs as a pendant to the great Olivares portrait,—fit rivals of the neighboring Charles V. by Titian, which doubtless fired Velazquez to excel himself, and both remarkable for their silvery tone, and their feeling of open air and harmony combined with brilliancy. The light plays on the armor and scarf thrown to the wind, showing how completely Velazquez had mastered the effects he strove to reach in his early days. Of these two great works Sir Richard Wallace possesses small but excellent replicas.

But, besides the forty portraits of Philip which are known, we have portraits of other members of the royal family, of Philip's first wife, Isabella of Bourbon, and her children, especially of her eldest son, Don Baltasar Carlos, of whom, besides those already mentioned, there is a beautiful full length in a private room at Buckingham Palace. Cavaliers, soldiers, churchmen, and poets of the court, as for example the Quevedo at Apsley House (Burlington House, 1887), sat to the painter and, even if forgotten by history, will live on his canvas. The admirable Pareja of Lord Radnor's collection (Burlington House, 1873) is said to have been taken by Philip for the living man. It has been remarked that the Spaniards have always been chary of committing to canvas the portraits of their beautiful women. Queens and infantas may be painted and exhibited, but ladies rarely. One wonders who the beautiful woman can be that adorns the gallery of Sir Richard Wallace, the splendid brunette so unlike the usual fair-haired female sitters to Velazquez. She belongs to this period of his work, to the ripeness of his middle period. Instinct with life, her bosom seems to heave and the blood to pulsate through her veins. The touch is firm but free, showing the easy strength of the great master. Rarely has flesh been painted with such a glow, yet with such reserve. This picture was one of the ornaments of the Bethnal Green collection. But, if we have few ladies of the court of Philip, we have in great plenty his buffoons and dwarfs. Even these deformed creatures attract our sympathy as we look at their portraits by Velazquez, who, true to his nature, treats them gently and kindly, as in El Primo (the Favorite), whose intelligent face and huge folio with ink bottle and pen by his side show him to be a wiser and better-educated man than many of the gallants of the court. El Bobo de Coria, El Niño de Vallecas, and Pablillos, a buffoon evidently acting a part, all belong to this middle period. From these commissioned portraits of the menials of the court it is pleasant to turn to one of the greatest of historical works, the Surrender of Breda, often known as Las Lanzas, from the serried rank of lances breaking the sky, which is believed to have been painted about 1647. It represents the moment when the vanquished Justin of Nassau in front of his Dutch troops is submissively bending as he offers to his conqueror Spinola the keys of the town, which, with courteous grace, the victor refuses to accept, as he lays his hand gently on the shoulder of his defeated foe.[2] Behind Spinola stand the Spanish troops bearing their lances aloft, while beyond is a long stretch of the Low Country, dotted with fortifications and giving the impression of vast space and distance. The picture is full of light and air and is perhaps the finest example of the silvery-bluish style of Velazquez. In conception it is as fine as in execution, and one looks in vain for a trace of "the malicious pencil" which Sir William Stirling-Maxwell discerned in the treatment of Justin and his gallant Dutchmen.

The greatest of the religious paintings by Velazquez belongs also to this middle period, the Christ on the Cross (Madrid gallery, No. 1055). Palomino says it was painted in 1638 for the convent of San Placido. It is a work of tremendous power and of great originality, the moment chosen being that immediately after death. The Saviour's head hangs on his breast and a mass of dark tangled hair conceals part of the face. The beautiful form is projected against a black and hopeless sky from which light has been blotted out. The figure stands absolutely alone without any accessory. The skull and serpent described by Sir William Stirling-Maxwell were added by some pious bungler at a much later date. The picture was lengthened to suit its place in an oratory; but this addition has since been removed.

---

[1] In this and in all his portraits Philip wears the *golilla*, a stiff linen collar projecting at right angles from the neck. It was invented by the king, who was so proud of it that he celebrated it by a festival, followed by a procession to church to thank God for the blessing (Madame D'Aulnoy, *Voyage d'Espagne*). The *golilla* was thus the height of fashion and appears in most of the male portraits of the period. In regard to the wonderful structure of Philip's moustaches, it is said that, to preserve their form they were encased during the night in perfumed leather covers called *bigoteras*.

[2] This gracious attitude is also employed by Velazquez in a picture in Stafford House (representing the reception of St. Francis Borgia by Loyola).

Velazquez's son-in-law Mazo had succeeded him as usher in 1634, and he himself had received steady promotion in the royal household, receiving a pension of 500 ducats [$1134.00] in 1640, increased to 700 {$1587.60] in 1648, for portraits painted and to be painted, and being appointed inspector of works in the palace in 1647. Philip now entrusted him with the carrying out of a design on which he had long set his heart, the founding of an academy of art in Spain. Rich in pictures, Spain was weak in statuary, and Velazquez was commissioned to proceed to Italy to make purchases. Accompanied by his faithful slave Pareja, whom he taught to be a good painter, he sailed from Malaga in 1649, landing at Genoa, and proceeding thence by Milan to Venice, buying Titians, Tintorettos, and Veroneses as he went. A curious conversation which he is said to have had with Salvator Rosa is reported by Boschini,[1] in which the Spaniard with perfect frankness confesses his want of appreciation of Raphael and his admiration of Titian, "first of all Italian men." It seems a possible story, for Velazquez bought according to his likings and painted in the spirit of his own ideals. At Modena he was received with much favor by the duke, and doubtless here he painted the two splendid portraits which now adorn the Dresden gallery, for these pictures came from the Modena sale of 1746. They presage the advent of the painter's third and latest manner, a noble example of which is the great portrait of Innocent X. in the Doria palace at Rome, to which city Velazquez now proceeded. There he was received with marked favor by the pope, who presented him with a medal and gold chain. Of this portrait, thought by Sir Joshua Reynolds to be the finest picture in Rome, Palomino says that Velazquez took a copy to Spain. There exist several in different galleries, some of them possibly studies for the original or replicas painted for Philip. One of the most remarkable is that in Apsley House, exhibited in Burlington House in 1887. The modelling of the stern impassive face comes near to perfection, so delicate are the gradations in the full light; all sharpness of outline has disappeared; and the features seem moulded by the broad and masterly brushwork. When closely examined, the work seems coarse, yet at the proper distance it gives the very essence of living flesh. The handling is rapid but unerring. Velazquez had now reached the *manera abreviada*, as the Spaniards call this bolder style. This is but another way of saying that his early and laborious studies and his close observation of nature had given to him in due time, as to all great painters, the power of representing what he saw by simpler means and with more absolute truth. At Rome he painted also a portrait of his servant Pareja, probably the picture of Lord Radnor's collection, which procured his election into the Academy of St. Luke. Philip was now wearying for his return; accordingly, after a visit to Naples, where he saw his old friend Ribera, he returned to Spain by Barcelona in 1651, taking with him many pictures and 300 pieces of statuary, which he afterwards arranged and catalogued for the king. Undraped sculpture was, however, abhorrent to the Spanish Church, and after Philip's death these works gradually disappeared.

Isabella of Bourbon had died in 1644, and the king had married Maria Anna of Austria, whom Velazquez now painted in many attitudes. He was specially chosen by the king to fill the high office of "aposentador major," which imposed on him the duty of looking after the quarters occupied by the court whether at home or in their journeys—a responsible function, which was no sinecure and interfered with the exercise of his art. Yet far from indicating any decline, his works of this period are amongst the highest examples of his style. The dwarf Don Antonio el Inglés (the Englishman) with his dog, Æsop, Menippus, and the Sculptor, all in the Madrid gallery, show his surest and freest manner. To these may be added the charming portraits of the royal children in the Louvre and Vienna, among the choicest of his works. It is one of these infantas, Margarita Maria, the eldest daughter of the new queen, that is the subject of the well-known picture Las Meniñas (the Maids of Honor) in the Madrid gallery, painted in 1656, where the little lady holds court, surrounded by her ladies-in-waiting, her dwarfs, and her mastiff, while Velazquez is seen standing at his easel. This is the finest portrait we have of the great painter, and, as etched by St. Raymond, it forms the frontispiece of the book by Mr. Curtis. It is a face of much dignity, power, and sweetness,—like his life, equable and serene, unruffled by care. Las Meniñas was the picture of which Luca Giordano said that it was the "theology of painting," another way of expressing the opinion of Sir Thomas Lawrence, that this work is the philosophy of art, so true is it in rendering the desired effect. The result is there, one knows not by what means, as if by a first intention without labor, absolutely right. The story is told that the king painted the red cross of Santiago on the breast of the painter, as it appears to-day on the canvas. Velazquez did not, however, receive the honor till 1659, three years after the execution of this work. Even the powerful king of Spain could not make his favorite a belted knight without a commission to inquire into the purity of his lineage on both sides of the house.[2] Fortunately the pedigree could bear scrutiny, as for generations the family was found free from all taint of heresy, from all trace of Jewish or Moorish blood, and from contamination by trade or commerce. The difficulty connected with the fact that he was a painter was got over by his being painter to the king and by the declaration that he did not sell his pictures. But for this royal appointment, which enabled him to escape the censorship of the Inquisition, we should never have had his splendid Venus and Cupid, belonging to Mr. Morritt of Rokeby Hall (exhibited in Manchester in 1857), painted in his latest manner and worthy of comparison with Titian. There were in truth but two patrons of art in Spain—the church and the art-loving king and court. Murillo was the artist favored by the church, while Velazquez was patronized by the crown. One difference, however, deserves to be noted. Murillo, who toiled for a rich and powerful church, left scarcely sufficient means to pay for his burial, while Velazquez lived and died in the enjoyment of good salaries and pensions. Yet on occasions Philip gave commissions for religious pictures to Velazquez,—among others, and belonging to this later period, the Coronation of the Virgin (Madrid), splendid in color—a harmony of red, blue, and gray—but deficient in religious feeling and dignity. It was painted for the oratory of the queen, doubtless Maria Anna, in the palace at Madrid. Another royal commission for the hermitage of Buen Retiro was the St. Anthony the Abbot and St. Paul the Hermit, painted in 1659, the landscape of which excited the warm admiration of Sir David Wilkie. The last of his works which we shall name is Las Hilanderas or the Spinners (Madrid), painted about 1656, representing the interior of the royal tapestry works. The subject is nothing, the treatment everything. It is full of light, air, and movement, splendid in color, and marvellous in handling. This picture, Raphael Mengs said, seemed to have been painted not by the hand but by the pure force of will. We see in it the full ripeness of the power of Velazquez, a concentration of all the art-knowledge he had gathered during his long artistic career of more than forty years. In no picture is he greater as a colorist. The scheme is simple,—a harmony of red, bluish green, gray, and black, which are varied and blended with consummate skill.

---

[1] See Stirling's *Velazquez and his Works*, p. 161

[2] The records of this commission have been found among the archives of the order of Santiago by M. Villaamil.

In 1660 a treaty of peace between France and Spain was to be consummated by the marriage of the infanta Maria Theresa with Louis XIV., and the ceremony was to take place in the Island of Pheasants, a small swampy island in the Bidassoa. Velazquez was charged with the decoration of the Spanish pavilion and with the whole scenic display. In the midst of the grandees of the first two courts in Christendom Velazquez attracted much attention by the nobility of his bearing and the splendor of his costume. On the 26th June he returned to Madrid and on the 31st July he was stricken with fever. Feeling his end approaching, he signed his will, appointing as his sole executors his wife and his firm friend Fuensalida, keeper of the royal records. He died on the 6th of August, 1660, passing away in the full possession of his great powers, and leaving no work behind him to show a trace of decay. He was buried in the Fuensalida vault of the church of San Juan, and within eight days his wife Juana was laid beside him. Unfortunately this church was destroyed by the French in 1811, so that his place of interment is now unknown. There was much difficulty in adjusting the tangled accounts outstanding between Velazquez and the treasury, and it was not till 1666, after the death of Philip, that they were finally settled.

Velazquez can hardly be said to have formed a school of painting. Apart from the circumstance that his occupations at court would have prevented this, his genius was too personal for transmission by teaching. Yet his influence on those immediately connected with him was considerable. In 1642 he befriended young Murillo on his arrival in Madrid, received him into his house and directed his studies for three years. His son-in-law Mazo painted in his manner, and doubtless many pictures by Mazo are attributed to the master. Carreño, though never a pupil, was a favorite and had the good sense to appreciate him and imitate him. His faithful slave Pareja studied his methods and produced work which by the favor of Velazquez procured his manumission from Philip. But the appreciation of the fine talent of Velazquez passed away quickly in Spain, as that country began to fall to pieces.

In addition to the standard works by Palomino, Cean Bermudez, and Pacheco, see the biographical notice by Don Pedro de Madrazo in his *Catalogo del Museo del Prado* (1872); *Velazquez and his Works* (1855) and *Annals of Artists of Spain* (1848), by W. Stirling (afterwards Sir W. Stirling-Maxwell); Ford's *Handbook to Spain* (1855) and his article in the *English Cyclopædia*; *Velazquez and Murillo*, by Charles B. Curtis (1883); the works of W. Burger (T. Thoré); *Gesch. d. Malerei*, by Woltmann and Woermann; Sir Edmund Head's *Handbook of Spanish Painting* (1848); *Works of Velazquez* (prints), by G. W. Reid (1872); *Gaz. d. Beaux Arts*, art. "Velazquez," by Paul Lefort (second period 1879–82); and Justi, *Diego Velazquez u. sein Jahrhundert*, 2 vols., Bonn, 1888. (J. F. W.)

VELEIA, a town of Liguria, near the frontier of Gallia Cisalpina, on the Apennine slope, about 20 miles to the south of Placentia. The "oppidum Veleiatium" is vaguely mentioned by Pliny as belonging to Liguria, but its exact site remained unknown until 1760, when its remains began to be recovered from under a mass of debris, which showed that the city must have been overwhelmed by a landslip from the neighboring mountain. Among the buildings that have been brought to light are a basilica, an amphitheatre, and several temples. Interesting antiquities from Veleia, including the "tabula alimentaria" of Trajan (see vol. xiii. p. 135), are deposited in the museum at Parma. None of the coins hitherto discovered on the site are later than the time of Probus (276–282).

VELEZ-MÁLAGA, a town of Spain, in the province of Malaga, and 15 miles east-northeast from that town, is finely situated in a fertile valley at the foot of steep mountains (Sierra Tejada), within a mile of the mouth of the small river Velez. Formerly it was a place of considerable commercial importance, but its prosperity has much declined in recent years, and it suffered severely in the earthquakes of 1884. It is associated with many romantic events in the history of the Moorish wars, to which period its old castle belongs. The vegetation of the neighborhood is most luxuriant, including the aloe, palm, sugar-cane, prickly pear, orange, vine, olive, and sweet potato. The inhabitants are chiefly employed in the various industries connected with the cultivation and export of the products of these. There is also a tunny fishery. The population within the municipal boundaries in 1877 was 24,332.

VELIZH, or **WELIZ**, a district-town of Russia, in the government of Vitebsk, on the Dwina, 53 miles northeast of the city of Vitebsk. It has an active trade in corn and linseed, grown in the neighboring provinces, and sent by river to Riga in exchange for fish, salt, tobacco, and groceries. The population (16,370 in 1885) has doubled since about 1860.

Velizh is supposed to have been originally founded by the Lithuanians, but it was deserted in the 16th century. In 1536 the Russians erected here a wooden fort, which, however, was soon taken by the Poles (1580) and it remained in their possession until 1772.

VELLEIUS. See PATERCULUS.

VELLETRI, a town of Italy, in the province of Rome, and 26 miles by rail to the southeast of that city, is picturesquely situated on a spur of Monte Artemisio on the southern edge of the Alban Hills and overlooking the Pontine marshes. The streets are steep, narrow, and irregular. In the highest part of the town are the municipal offices, with an important inscription relating to the restoration of the amphitheatre under Valentinian and Valens. Velletri is the seat of the bishop of Ostia; the cathedral (1660) contains some good sculpture of the school of Sansovino. The neighborhood produces a celebrated wine, a chief source of wealth to the town. The population in 1881 numbered 13,532.

At the close of the Latin War (336 B.C.) the Volscian Velitræ had its walls razed to the ground and its leading inhabitants banished beyond the Tiber, their lands being given to Roman settlers. It became a flourishing municipium, and was the native place of the Octavian family. In the neighborhood of Velletri Don Carlos, younger son of Philip V. of Spain, in 1734 gained over the Austrians a decisive victory, which ultimately secured him as Charles III. the kingdom of the Two Sicilies.

VELLORE, a town and military cantonment of India, in North Arcot district of the Madras presidency, on the right bank of the river Palár in 12° 55′ 17″ N. lat. and 79° 10′ 17″ E. long. It has a strongly-built fortress, which was famous in the palmy days of the Carnatic, and which is overlooked by hills in the vicinity. In 1780 it withstood a siege for two years by Hyder Ali. After the fall of Seringapatam (1799) Vellore was selected as the residence of the sons of Tippoo Sahib, and to their intrigues has been attributed the revolt of the sepoys at Vellore in 1806. Besides the fortress, the town contains a handsome Vishnuvite temple with some good carving. In 1881 the population was 37,491 (males 17,605, females 19,886).

VELVET is a silken textile fabric having a short dense piled surface. It is the type of the numerous forms of piled fabric now made, the processes employed in the manufacture of which are noticed under WEAVING (*q.v.*). In all probability the art of velvet weaving originated in the far East; and it is not till about the beginning of the 14th century that we find any mention of the textile. Fustian, however, which differs from velvet only in material, is spoken of in English ecclesiastical inventories as early as the beginning of the 13th century. The peculiar properties of velvet, the splendid yet softened depth of dye-color it exhibited, at once marked it out as a fit material for ecclesiastical vestments, royal and state robes, and sumptuous hangings; and the most magnificent textures of mediæval times were Italian velvets. These were in many ways most effectively treated for ornamentation, such as by varying the color of the pile, by producing pile of different lengths (pile upon pile, or double pile), and by brocading with plain silk, with uncut pile, or with a ground of gold tissue, etc. The earliest sources of European artistic velvets were Lucca, Genoa, Florence, and Venice, and to the present day Genoa continues to send out rich velvet textures. Somewhat later the art was taken up by Flemish weavers, and in the 16th century Bruges attained a reputation for velvets not inferior to that of the great Italian cities. The principal seats of the modern manufacture are Crefeld and Lyons; but, at the former centre especially, a large proportion of an inferior texture, having a silken pile on a cotton foundation and known as *velveteen*, is now made.

VENANTIUS. See FORTUNATUS.

VENDACE is the name of a British freshwater fish of the genus *Coregonus*, of which two other species are indigenous in the fresh waters of the British Islands, viz., the gwyniad and the pollan. The vendace (*C. vandesius*) is restricted to some lochs in Dumfriesshire, Scotland; it is, however, very similar to a species (*C. albula*) which inhabits some of the large and deep lakes of northern Europe. From its general resemblance to a dace the French name of the latter, *vandoise*, was transferred to it at the period when French was the language of the court and aristocracy of Scotland. So great is the local celebrity of the fish that a story has been invented ascribing to Mary Queen of Scots the merit of having introduced it into the Lochmaben lochs. It is considered a great delicacy, and on favorable days when the shoals rise to the surface, near the edges of the loch great numbers may be taken. It spawns in November. In length it scarcely exceeds 8 inches.

Authentic accounts of the vendace have been published by Sir William Jardine, in *Edinb. Journ. of Nat. and Geog. Science*, iii. p. 4, 1830, and by Robert Knox, in *Trans. Roy. Soc. Edinb.*, xii. p. 503, 1834.

VENDÉE, a maritime department of France, formed in 1790 out of Bas-Poitou, and taking its name from an unimportant tributary of the Sèvre Niortaise, lies between 46° 16′ and 47° 5′ N. lat. and 0° 32′ and 2° 10′ W. long., and is bounded by Loire-Inférieure and Maine-et-Loire on the N., by Deux-Sèvres on the E., by Charente-Inférieure on the S., and by the Atlantic Ocean on the W. for 93 miles. The islands of Yeu (or Dieu) and Noirmoutier are included. The Sèvre Nantaise on the N.E. and the Sèvre Niortaise on the S., besides other streams of minor importance, form natural boundaries. The department falls into three divisions—woodland, plain, and marsh. The highest point (945 feet) is situated in the woodland, which occupies the greater part of Vendée, on the water-parting between the Loire and the rivers of the coast. This region, which, geologically, is composed of granite, gneiss, mica-schist, schist, and lias, abounds in springs, and is fresh and verdant; the landscape is characterized by open fields surrounded by trees, which supplied ambushes and retreats to the Vendéans in the civil war at the end of the 18th century. The plain of Vendée is bare and treeless, but fertile, though poor in springs; geologically it is composed of lias and oolite. The marshes, raised above the sea-level within historic times (four centuries ago), consists of two portions, the Breton marsh in the north and the Poitevin marsh in the south. The region includes salt marshes and cultivated areas artificially drained. Its area is constantly being increased by the alluvium of the rivers and the secular elevation of the coast. The department is drained by the Sèvre Nantaise (tributary of the Loire) and the Boulogne (a feeder of Lake Grandlieu in Loire-Inférieure), both draining into the basin of the Loire; and by the Vie, the Lay (with the Yon), and the Sévre Niortaise with the Autise and the Vendèe), which flow into the Atlantic. The climate is that of the Girondin region, mild and damp, the temperature rarely rising above 77° or falling below 18° Fahr.; 120 to 150 days of rain give an annual rainfall of 30 inches. The woodland is colder than the plain, and the marsh is damp and unhealthy.

Out of the total area of 1,656,531 acres arable land occupies 1,023,275 acres, grass 290,503, vines, 37,467, wood 65,853, and moor, pasture, and uncultivated land 136,432. In 1881 the live stock included 29,790 horses, 4500 mules, 1950 asses, 471,775 cattle, 379,950 sheep (10,000 being of superior breed; total wool-clip 395 tons), 55,000 pigs, and 1625 goats. There were 10,000 beehives (49 tons of honey and 10 tons of wax). The agricultural products in 1884 were returned as follows: wheat 7,312,316 bushels, meslin 65,736, rye 218,720, barley 1,218,855, buckwheat 358,985, maize 33,000, millet 129,973, oats 2,815,436, potatoes 3,938,214, beet-root 324,601 tons, wine 15,569,312 gallons, colza seed 7790 tons, hempseed 551 tons, linseed 991 tons, flax 1786 tons, and fodder 745,792 tons. The forests (oak, chestnut, pine, poplar, hornbeam, maple, ash, beech, and elm) yielded 3,180,000 cubic feet of wood, a third of which was applied to various industrial uses. Apples, pears, peaches, plums, cherries, and walnuts are the principal fruits grown. The salt marshes, 4572 acres in extent and employing 3500 workmen, yielded 2436 tons of salt in 1882. In 1884 18,409 tons of coal were mined. Iron, antimony, lead, "the Vendée diamond" (a kind of quartz), china clay, and slate are obtained; and granite, gneiss, slate schist, limestone, cement, millstones, and clay are objects of industry. The celebrated beds of sea-shells near St. Michel-en-l'Herm—2300 feet long, 985 broad, and from 30 to 50 feet in depth—show to what an extent the coast has risen. The wool spinning and weaving industry occupies 12,570 spindles and 520 hand-looms; cotton, 3100 spindles and 5 looms; linen, 388 spindles and 478 looms (80 being power looms). There are potteries, paper mills, tan-yards, dye-works, a glass-work, manufactories of hats, boots and shoes, and lampblack, flour mills, distilleries, tile-works, and shipbuilding yards, and sardines and tinned foods are prepared,—in all 575 industrial establishments. The sardine fishery occupies 800 boats and 2000 men, and there are extensive oyster beds near Sables-d'Olonne. Corn, cattle, mules, fish, salt, wine, honey, wood, glass, and manure are exported; wine, wood, building material, and coal are among the imports. The shipping places are Bouin and Beauvoir in the Breton marsh and Noirmoutier, the island of Yeu, St. Gilles-sur-Vie, Sables-d'Olonne, L'Aiguillon, and Luçon in the Poitevin marsh. In 1882 a total of 391 vessels (130,688 tons) entered and cleared from all these ports. Vendée has 212 miles of railway, 335 of national and 2966 of other roads, and 82 of navigable rivers and canals. In 1881 the population was 421,642, and in 1886 434,808,—an increase of 191,382 since 1801. The department forms the diocese of Luçon, has its court of appeal, and academy at Poitiers, and is included in the district of the Nantes army corps. There are three arrondissements (La Roche-sur-Yon, the chef-lieu of the department, with 10,991 inhabitants in 1886; Fontenay-le-Comte, 9282; and Sables-d'Olonne, 10,114), 30 cantons, and 300 communes. Luçon (6285 inhabitants) is connected with the sea by a canal, and has a cathedral of the 11th, 13th, 14th, 16th, and 18th centuries, with an elegant Gothic spire, a cloister of the 15th and 16th centuries, an episcopal palace, and a hospital, with portraits of the bishops of Luçon.

VENDÔME, a town of France, chef-lieu of an arrondissement in the department of Loir-et-Cher, is situated on the river Loir, 109 miles southwest of Paris by the railway to Tours, at the junction of the line from Blois to Le Mans. The abbey of the Trinity (12th to 15th century) has a fine portal in florid Gothic style. A graceful balustrade runs round the building at the spring of the roof, and two rows of flying buttresses, themselves resting on other elegant buttresses, support the nave. The high gallery of the triforium, the rich traceries of the windows, and the modern fonts are worthy of notice. Part of the building is in the Angevin style of the beginning of the 13th century. In the choir are some fine stalls and glass of the 15th and 16th centuries. The steeple, 262 feet high, which stands isolated in front of the church, belongs to the middle of the 12th century, and is one of the finest examples of Transition architecture. The lower part is rectangular and the upper octagonal, with a stone spire. It has been recently restored. The church of La Madeleine (15th century) is surmounted by a stone spire, an indifferent imitation of that of the abbey. The fine tower of St. Martin (16th century) is all that remains of the church of that name. The town-hall occupies the old gate of St. George; its river front is composed of two large crenellated and machicolated towers, connected by a pavilion. The ancient hospital of St. James afterwards became a college of the Oratorians, in which Mascaron was a professor, but is now a lyceum; the charming chapel, dating from the 15th century, in the most florid Gothic style, is still preserved. Parts of the chateau of the counts of Vendôme are as old as the 11th century. A public promenade leads to the curious vaults under the castle. Vendôme is the seat of an archæological and scientific society, possesses a library of 15,000 volumes and 305 MSS., and a museum, mostly archæological, in front of which stands a statue of Ronsard. There are some interesting houses of the 15th and 16th centuries, and near the town are the remains of a Roman theatre. The population in 1881 was 7913, (commune 9420), the corresponding figures for 1886 being 7843 and 9325.

Vendôme (*Vindocinum*) appears originally to have been a Gallic oppidum, replaced later by a feudal castle, around which the modern town has arisen. Christianity was introduced by St. Bienheuré in the 5th century, and the abbey of the Trinity was founded in 1030. About the end of the 10th century Vendôme became an independent county, and was raised to a duchy in 1515. It long belonged to a branch of the Bourbon family. During the Wars of Religion the town was sacked by the Protestants, by members of the League, and was finally taken by Henry IV. Since then its industrial and commercial importance (tanneries and manufactories of woollen stuffs and gloves) has fallen off. Marshal de Rochambeau was a native of Vendôme.

VENEERING is the art of attaching thin sheets or leaves of wood, ivory, etc., to the surface of wood or other material of a less costly or less ornamental description. It is thus in connection with wood, ivory, etc., equivalent to plating in the working of metals. The art is largely practiced in cabinet-work. Veneers are either cut or sawn from solid blocks or planks. The ordinary veneer saw is a circular instrument of large diameter, made up of segments of thin steel bolted on a strong circular iron frame, which gives the requisite stiffness and rigidity to the saw edge. The teeth of the saw are minute and finely set, so as to waste as little as possible of the valuable material as sawdust. With such a saw from 8 to 16 leaves per inch may be cut out of a block of wood and as many as 30 leaves of ivory, one-third of the solid being reduced to sawdust. Veneers are also made from certain straight-grained and pliant woods with cutting tools, either by the process of planing or of turning. For these methods of veneer-making, the wood to be operated on is first reduced to blocks of a size equal to the cutting edges by which they are to be made into veneer, and are then steamed in a close chamber to soften the fibre. In the plane veneer-cutting machines the block of wood may be stationary and the cutter movable, or *vice versa*, and the cutting edge is applied obliquely to the block. Immediately in front of the cutter pressure is applied to the block to keep the shaving from splitting up. With the planing machine from 100 to 150 veneer leaves can be cut from each inch of thickness. By the lathe-turning method continuous strips of veneer are obtained from circular blocks the width of the cutter, and it is possible to reduce the block till a core of about only 9 inches remains. In the cutting, as opposed to the sawing, of veneers there is no waste whatever of the solid material; but cut veneers are not so serviceable, and the most valuable veneer woods, being hard, cross-fibred, and brittle, cannot be treated otherwise than by sawing. In veneering, the surfaces to be united, after roughening, so as to give grip, are coated with thin glue applied very hot, and then tightly pressed together in a veneering press, with heated cauls or plates of zinc applied to their surfaces, these cauls being contoured to the necessary outline when bent veneers are being planted. Should the veneer show any blistering after removal from the press, heat, damp, and local pressure are applied till veneer and wood are solidly cemented together. The surface is afterwards smoothed, polished, and finished as in dealing with solid cabinet woods.

VENEREAL DISEASES. See PATHOLOGY, vol. xviii. pp. 414–15, and SURGERY, vol. xxii. pp. 721–22.

Plate IV.

VENEZUELA,[1] a federal republic in South America, being between about 57° and 73° 30′ W. long. and 1° 40′ and 12° 26′ N. lat. The republic claims that the area of its territory is 632,807 square miles; but the boundaries are not yet definitely fixed, and its area is consequently uncertain. In the southwest it claims large tracts extending to the south of the equator, which are also claimed by Colombia and Ecuador; and in the east it claims from British Guiana the upper valley of the Essequibo, together with all the territory on the left bank of that river below the influx of the Rupununi. Of the total area claimed only about 439,000 square miles are actually under Venezuelan administration.

Physical Features.—A branch of the eastern chain of the Andes enters Venezuela in the west about 7° N. lat., and under the name of the Sierra Nevada de Merida proceeds northeastwards towards Triste Gulf. This branch consists of parallel chains enclosing elevated valleys, in one of which lies the town of Merida at the height of 5400 feet, overlooked by the highest summit of the chain (Picacho de la Sierra, 15,000 feet). The sierra contains the water-parting between the basin of the Orinoco and those of the small rivers on the northwest. Hence it may be considered to terminate where the Rio Claro, the stream on which Barquisimeto stands, after rising on its western slopes flows eastwards into the basin of the Orinoco. Beyond the Claro begin two parallel ranges known as the Maritime Andes of Venezuela, which stretch east and west along the coast. The valley between these two ranges is the most densely peopled part of Venezuela. Within it lie the town of Valencia (1800 feet), the Lake of Valencia (1400 feet), and the town of Carácas (3000 feet). Above Carácas the highest peak of the system, Pico de la Silla, rises to 8740 feet. Behind the wide bay between Cape Codera and Cumana there is an interruption in the Maritime Andes; but both ranges reappear between Cumana and the Gulf of Paria. West of the Maritime Andes low ranges (3500–5000 feet) trend northwards from the end of the Sierra de Merida towards the coast, on the east side of the Lake of Maracaibo, while the region on the west of that lake consists of lagoon studded lowlands. East and south of the Sierra de Merida and Maritime Andes the Venezuelan territory consists mainly of the basin of the Orinoco. This region is for the greater part of its extent thinly populated and little known. It consists of two portions,—a vast hilly or mountainous area, densely wooded, in the southeast and south, and level plains in the northwest between the Orinoco and the Apure and the mountains. The latter is known as the llanos of the Orinoco, a region described by Humboldt as a vast "sea of grass," with islands of wood scattered here and there. Since the time of Humboldt, however, the aspect of these plains would seem to have changed very consider-

---

[1] The name means "little Venice." and is a modification of the name Venecia (Venice), originally bestowed by Alonzo de Ojeda in 1499 on an Indian village composed of pile-dwellings on the shores of the Gulf of Maracaibo, which was called by him the Gulf of Venecia.

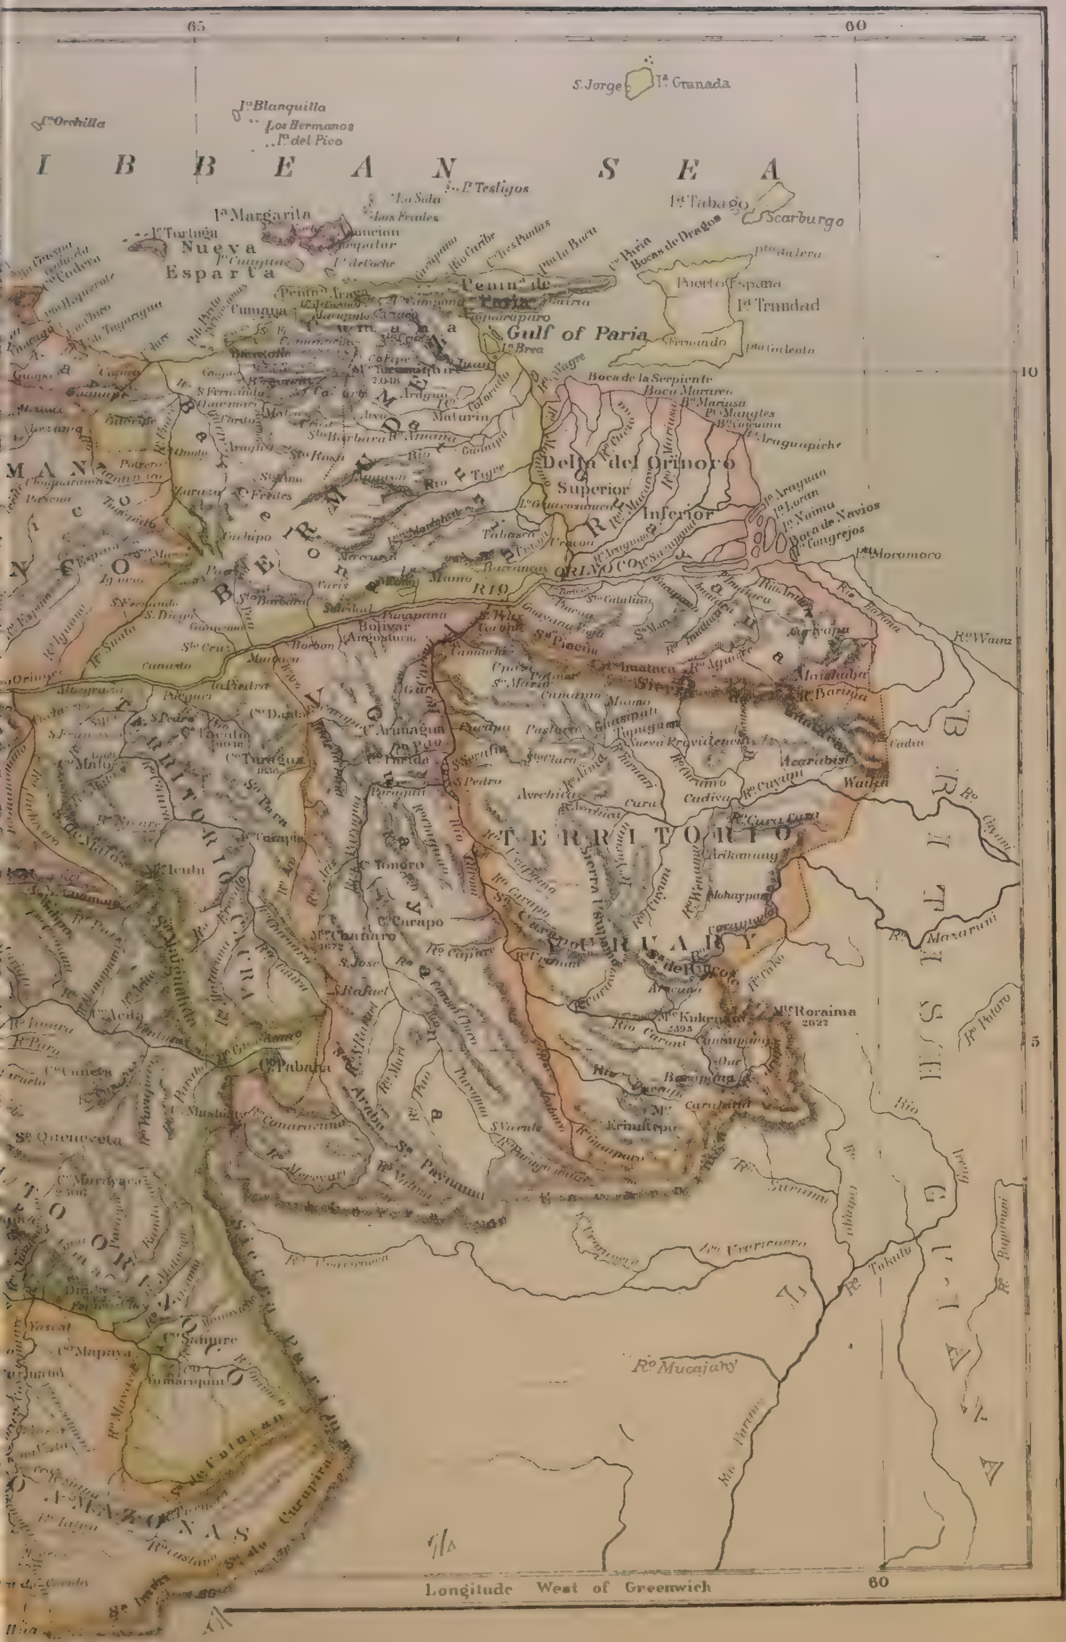
VELA. PLATE IV.



ably. On the occasion of Appun's visit in 1850 trees seem still to have been comparatively rare; but a different aspect was presented when Dr. P. Jonas visited the llanos in 1878. From the Galera, the southernmost range of hills north of the Orinoco basin, the traveller saw a vast plain thickly grown with low trees, among which the chaparro was chiefly represented. Few places were quite destitute of trees, and these of small extent. As far as Calabozo (about one-third of the distance between the hills and the Apure) it was now chaparros (evergreen oaks), now mimosas, which were the prevailing feature of the landscape, though other trees were not rare. But towards the south the open grass-covered spaces increased in number and area. To the south of Calabozo woods of considerable extent were seen. This change in the character of the landscape is due to the decline of horse and cattle rearing in the llanos, partly in consequence of political disturbances and partly of a murrain which broke out in 1843 among horses, mules, and asses, and in that and several subsequent years reduced their numbers by several thousands.

Geology.—Geologically the chief mountain ranges of Venezuela are all similar in structure. The nucleus of the Sierra Nevada de Merida is formed of plutonic or metamorphic rock (granite, syenite, gneiss, crystalline schists, etc.), and this series is continued throughout the northern chain of the Maritime Andes. Stratified rocks belonging to the Cretaceous system are found on both sides of the plutonic nucleus of the former range, and are those chiefly seen in the southern chains of the Maritime Andes. Most of these deposits belong to the upper members of the Cretaceous system; but the lower members come to the surface in considerable patches west of the Sierra Nevada de Merida, and in the chains just referred to. Tertiary and Quaternary deposits (generally as compact marl, sand, shingle, and conglomerate) are spread over nearly all the llanos, as well as round the Gulf of Maracaibo, and in the plains drained to the north by the Unare, between the two sections of the Maritime Andes. The hills and mountains east of the Orinoco, according to Humboldt, Schomburgk, and Codazzi, seem to be mainly composed of granite, syenite, and other crystalline rocks.

Climate.—The climate and vegetation are such as might be expected from the tropical situation of the country. But Venezuela, as well as the rest of tropical South America east of the Andes, is directly exposed to the trade-winds. The temperature is thereby considerably moderated, and no such extremes of heat are to be met with as are experienced in the corresponding latitudes of northern Africa. The more populous parts of Venezuela are, however, hotter than the maritime districts of Guiana, being less directly exposed to the Atlantic breezes. At La Guaira the mean temperature of the year is 85° Fahr.; at Carácas, only 10 miles distant, but 3000 feet higher, it is 71.2° Fahr.; and the greatest extremes that have been observed at the latter station since 1868 are 83.4° and 48° Fahr. At both stations the hottest periods are the middle of April and the end of August, when the sun is in the zenith. Everywhere there is a well-marked distinction between a dry and a rainy season, the latter occurring in the English summer months, when the sun is in the northern hemisphere and the force of the trade-wind on the north coast of South America is considerably slackened. At La Guaira the rainy season proper lasts only three months (May to August); but this season lasts longer in the mountains and in the llanos.

Fauna.—The fauna includes among the mammals the rodents and carnivores common to the rest of tropical South America. The manatee is met with nearly everywhere on the coast. In all the rivers are to be found caymans, electric eels, rays, and caribs, the last (*Pygocentrus piraya, P. nigricans, P. niger*, Müll.) consisting of several species of savage and voracious fishes armed with two rows of very sharp teeth. Among the venomous serpents are the striped rattlesnake (*Crotalus durissus*), *Lachesis mutus*, an ally of the rattlesnakes, and a rather rare species of *Cophias*. Among the non-venomous sorts the commonest are the boa constrictor, the anaconda (*Eunectes murinus*), and the *Coluber variabilis*. Among birds is a singular form known from its note as the bell-bird (*Chasmorhynchus carunculatus*). Coral banks abound on the coast; like the waters which surround the roots of the mangroves, these teem with marine life, and are peculiarly rich in beautifully colored crustaceans. Swarms of locusts sometimes commit great ravages among the fields and plantations.

Flora.—The lower slopes of all the mountains are clad with the richest tropical vegetation. Amidst an endless variety of dicotyledonous foliage trees, interlaced by numerous twiners and climbers and adorned with epiphytic orchids, *Tillandsiæ*, aroids, and *Loranthaceæ*, grow numerous palms and tree-ferns, up to the height of about 3500 feet. From among the forest trees may be singled out for mention the silk-cotton tree (*Bombax Ceiba*), the mango (*Mangifera indica*), the saman (*Inga saman*),—remarkable, like the last-mentioned, less for its height than for the extent and density of the shade which it casts,—the cow-tree (*Brosimum Galactodendron*), and the *Attalea speciosa*,—this last being one of the finest ornaments of the palm tribe, a tree whose stem, 40 feet in height, carries erect on its crown leaves which also grow to a height of 40 feet, with a breadth of 8 feet. The mouths of the Orinoco and many parts of the coast are rendered unhealthy by mangrove swamps, which are no doubt partly to blame for the yearly recurrence of yellow fever in many of the coast towns. From these swamps, however, La Guaira is free, and there the yellow fever is not a regular visitant.

Vegetable Products.—The two chief crops grown for food are manioc and maize, the latter being generally ground coarse and baked into a kind of cakes called *arepas*, which are eaten hot like the Mexican tortillas. Among other vegetable products which take an important place in the Venezuelan dietary are all kinds of tropical fruits, including several kinds of melons and pumpkins, the sugar-cane (the sugar, in a little refined condition, known as *papelon*, being a favorite article of food), the taro, sweet potatoes, various beans (including two species of *Phaseolus*, which grow only high up in the mountains, but are highly prized everywhere), and a species of hemlock (*Conium moschatum*), which is eaten like celery. Of plantation products grown for export by far the most important are coffee and cocoa, next after which come tobacco and cotton. The following table (I.) shows (in thousands of ℔) the variations in the export of these products in several years since 1830–31:

Year.	Coffee.	Cocoa.	Tobacco.	Cotton.	Year.	Coffee.	Cocoa.	Tobacco.	Cotton.
1830–31	11,684	7304	103	98	1864–65	28,497	8,386	548	5405
1840–41	26,316	7770	1212	2038	1874–75	72,263	10,725	337	4601
1850–51	38,432	8259	1539	781	1885–86	86,115	11,268	156	273

This table clearly shows that coffee is rapidly taking a more and more important place as the leading staple of Venezuela. The only date at which the export of coffee shows a decline as compared with the previous date mentioned is 1864–65, when it is clear, from a comparison of this column with that under cotton, that a considerable area must have been temporarily given up to the cultivation of cotton in consequence of the Civil War in the United States. As regards quantity, Venezuela held the fifth place among the coffee-exporting countries of the world on an average of the ten years 1872–82.[1] Both coffee and cocoa are grown under the shade of erythrinas, the scarlet racemes of which at the flowering season impart a brilliant aspect to the plantations. Besides the products above-mentioned, indigo and sugar at one time figured largely among the exports of Venezuela; but both of them have now almost disappeared from the list of exports, the former in consequence of the decline in cultivation, the latter because of the increasing consumption of papelon among the inhabitants.

The following table (II.) shows, in thousands of acres, the extent of land under the principal crops in 1875, according to Codazzi, and in 1883 according to official estimates:

	1875.	1883.		1875.	1883.
Coffee	335.7	343.1	Manioc	42.5	67.9
Sugar-cane	86.0	97.1	Cocoa	50.9	60.8
Bananas	69.2	92.4	Tobacco	9.9	15.6
Vegetables	....	97.1	Various fruits	....	21.2
Maize	42.5	67.9	Cotton	14.8	4.9

Live-Stock.—The number of live-stock was officially returned in 1883 as follows: cattle 2,926,733; sheep and goats 3,490,563; horses 291,603; mules 247,703; asses 658,764; pigs 976,500.

---

[1] Ranking after Brazil, Java, Ceylon, and Hayti.

Minerals.—The principal minerals of Venezuela are gold, copper, phosphates, and coal. The rich auriferous deposits on the banks of the Yuruari lie 100 miles southwest of the principal mouth of the Orinoco. At Aroa in the northwest, about 75 miles west of Puerto Cabello, are rich deposits of copper ore. Phosphates are obtained from the islands of Orchilla and Aves, which lie to the east of the Leeward Islands of the Dutch. A large deposit of bituminous coal, said to be of very good quality, exists about 6 miles south of Barcelona, and a concession for a railway from this port to the coal-bed has been obtained from the Government. Another extensive deposit of bituminous coal has been found on the banks of the Utare, a small stream which empties itself into the sea about 40 miles east of La Guaira. Good petroleum is refined from deposits worked near Belijoque in the state of Los Andes. Both gold and copper ore are important exports, gold ranking in this respect next after coffee. The total amount of gold exported from Ciudad Bolivar from 1866 to 31st December, 1886, so far as the export was controlled by the state, was 1,946,383 oz.; but it is estimated that within that time about half a million oz. were smuggled away. During the five years 1882–86 the average annual yield was about £740,000 [$3,596,400]. The field from which this yield is derived is at present one of the most promising in the world, but the frontier disputes between Great Britain and Venezuela interfere with the investment of capital for the development of some portions of it to which both Governments lay claim. Silver and tin are also met with, but neither has yet attained any commercial importance.

Industry.—Manufacturing industries are in general undeveloped. Artisans from Europe and North America are now settled in all the chief towns, and cotton weaving factories have been established. The manufacturing industries most extensively pursued are the making of shoes and hats. The latter industry is chiefly in the hands of Germans. A material called jipijapa is very largely used for the making of a kind of hats in imitation of Panama straw hats.

Commerce.—The total value of the imports amounted in the year 1885–86 to £2,498,135 [$12,140,936.10], and that of the exports to £3,292,171 [$15,999,951.06]. The principal exports, besides the plantation products and minerals already mentioned, are hides and skins, coir, and animals; those of minor importance are starch, indigo, sugar, tonqua beans, cinchona, caoutchouc, divi-divi, cocoa-nuts, copaiba balsam, plants, and timber. The principal imports are manufactured articles, drugs, and wine, the last from Spain. Petroleum is imported from the United States, though it is expected that the native supplies will soon meet the home demand. Foreign commerce is chiefly carried on with the United States, Germany, France, and England. There is also a coasting trade of considerable magnitude (value £2,382,719 [$11,580,014.34] in 1883). The chief seaports are La Guaira (14,000 inhabitants) and Puerto Cabello (10,145), which has the finest natural harbor in Venezuela, enclosed by a ring of coral reefs; the next in importance are Maracaibo (31,921), Ciudad Bolivar (10,861), Carupano (12,389), Puerto Sucre, Puerto Guzman Blanco, La Vela (the port of Coro, opposite the island of Curaçao), and Guiria (on the Gulf of Paria). Ciudad Bolivar is 236 miles up the river Orinoco, the navigation of which by any mouth has been free to all nations since the 25th of October, 1886.

Communication.—The total length of railways open at the end of 1886 was 144 miles, and 263 miles were then in construction. The length of telegraph lines at the same date was 2595 miles. The railways already in existence or in construction are all short lines connecting the chief seaports with the nearest important inland towns or seats of mineral production, or lines radiating to the more important towns round Carácas. The principal inland towns, besides CARÁCAS (*q.v.*), the capital (population 70,509 in 1883), are Valencia (36,145), Barquisimeto (28,198), Merida (10,747), Calabozo, Barinas, Nutrias, and Maturin (14,743).

Population, Area, etc.—The republic is divided into eight states, eight federal territories, the federal district, and two national colonies, the names of which, with their area in square miles and their population according to an official estimate for 1st January, 1886, are given in the accompanying table.

Armisticio, Alto Orinoco, Amazonas, Yuruari, and Delta include the disputed tracts of territory. The population of Caura in the following table is included in that of the state of Bolivar, the population of Armisticio and Delta in that of the states of Bolivar, Zamora, and Los Andes, and of the colony of Bolivar in that of the state of Guzman Blanco. The agricultural colonies are under the administration of a governor subordinated to the ministry of progress (*del fomento*). The pure white population is estimated at only 1 per cent. of the whole, the remainder of the inhabitants being Negroes (originally slaves, now all free), Indians, and mixed races (mulattos and zambos).

	Area.	Population.		Area.	Population.
States—			Yuruari.......	81,123	19,852

Territories—			Bolivar.........	9	....
Alto Orinoco } Amazonas... }	119,780	38,340		594,197	2,198,320

Religion, Education, etc.—The Roman Catholic is the religion of the state, but liberty of worship is guaranteed by law. So far as legislative enactment goes, elementary education is now well provided for; but in the year ending 30th June, 1886, the total number of common, municipal, and private schools was 1957, and the number of pupils 99,466. There are also two universities (Carácas and Merida), 19 federal colleges, and various other public and private institutions for higher education. The standing army consists of about 2800 men, but every male subject between eighteen and forty-five has to be enrolled in the national militia. The monetary system of Venezuela is that of the Latin convention, the franc being represented by the *bolivar*. The French metric system of weights and measures is likewise the legal system; but the old weights, the libra = 1.014 ℔ avoir., the quintal = 101.4 ℔ avoir., and the arroba = 25.35 ℔, are also in use.

Finance.—The revenue, which is chiefly derived from customs duties, amounted in 1885–86 to £1,093,644 [$5,315,109.84] and the expenditure to £1,239,400 [$6,023,484]. The public debt, of which the external portion alone amounted in 1878 to nearly £11,000,000 [$53,460,000], including arrears of interest, was reduced in 1881 to a total of £4,000,000 [$19,440,000] by the issue of new bonds in place of all the old ones, both external and internal. At the end of 1886 the external debt amounted to £2,680,850 [$13,028,931], bearing interest at 4 per cent.

Constitution.—The constitution is modelled to some extent on that of the United States. At the head of the executive is a president, who is assisted by eight ministers and a federal council. The legislative authority is vested in a congress of two houses,—a senate (24 members) and a chamber of deputies (52 members). The members of the chamber of deputies (one for every 35,000 inhabitants, and one more for an excess of 15,000) are elected every four years directly by the electors of the states and the federal district, those of the senate by the legislative bodies of the different states (three for each). The congress elects the members of the federal council, in which there is one senator and one deputy for each of the political divisions of the republic, and one deputy for the federal district. The federal council elects the president. The federal council and the president remain in office for two years.

History.—The coast of Venezuela was the first part of the American mainland sighted by Columbus, who, during his third voyage, in 1498, entered the Gulf of Paria and sailed along the coast of the delta of the Orinoco. In the following year a much greater extent of coast was traced out by Alonzo de Ojeda, who was accompanied by the more celebrated Amerigo Vespucci. In 1550 the territory was erected into the captain-generalcy of Carácas, and it remained under Spanish rule till the early part of the 19th century. During this period Negro slaves were introduced; but less attention was given by the Spaniards to this region than to other parts of Spanish America, which were known to be rich in the precious metals.

In 1810 Venezuela rose against the Spanish yoke, and on 14th July in the following year the independence of the territory was proclaimed. A war ensued which lasted for upwards of ten years, and the principal events of which are described under BOLIVAR (*q.v.*), a native of Carácas and the leading spirit of the revolt. It was not till 30th March, 1845, that the independence of the republic was recognized by Spain in the treaty of Madrid. At the date of the battle of Carabobo (1821), by which the power of Spain in this part of the world was broken, Venezuela formed part of the federal state of Colombia, which embraced also the present Colombia and Ecuador; but a meeting of Venezuelan notables on 26th November, 1829, declared for the separation of their country from the confederacy. Venezuela passed through the first years of its independent existence with more quietness than the other members of the confederacy. In 1846 there began a series of civil wars and revolutions, which continued, with but short periods of rest, down to the close of 1870. The chief rival parties in these internal dissensions were the Unionists and the Federalists; the former aimed at securing a strong central Government, while the latter, who were ultimately victorious, desired to obtain a large measure of independence for separate states. It was during these troubles that the emancipation of the slaves took place, under a law of 24th March, 1854. On 28th March, 1864, a federal constitution was drawn up for the republic. Three years later, however, the civil war broke out again, and matters continued in an unsettled state, till in December, 1870, Don Guzman Blanco, who had taken the leading part on the side of the Federalists, was declared provisional president. From that date Blanco acted as dictator till 20th February, 1873, when he was elected constitutional president for four years, and it has been chiefly owing to his energy and ability that the confederacy has since proceeded on a course of orderly development. The two flourishing agricultural colonies already mentioned were founded during his first tenure of office, in 1874. The chief event in recent years has been the re-division of the territory in 1881 into the states and territories whose names are given in the table above.

Spence, *The Land of Bolivar*, London, 2 vols., 1878. Regarding the geology, see Hermann Karsten, *Géologie de l'Ancienne Colombie Bolivarienne* (with a geological map and eight plates), Berlin, 4to, 1886; and a paper on the gold mines of Venezuela by C. Le Neve Foster, in *Quart. Journ. Geol. Sc.*, vol. xxv., 1869. Regarding the fauna and flora, see A. Ernst, *Estudios sobre la Flora y Fauna de Venezuela*, Carácas, 1877, 4to. There is a map of Venezuela by A. Codazzi in four sheets, with views and statistical tables, 1876; and a physical and political map accompanies the *Statistical Annuary* issued by the ministry of progress (Carácas, 1887).

(G. G. C.)

VENICE.

PART I.—HISTORY.

Origin of the state.

ALTHOUGH the numerous marshy islands of the lagoons extending along the northwestern shores of the Adriatic between Altinum and Adria are known to have been largely used from the beginning of the 5th century by the inhabitants of Venetia (compare vol. xiii. p. 446)—one of the twenty-nine provinces into which Italy was divided by Constantine—as temporary retreats from successive barbarian invasions, the first permanent settlement on the site of the present city of Venice—the Rivo Alto (Rialto) and its numerous adjacent islets—cannot with certainty be traced further back than to the beginning of the 9th century. The physical conditions with which the earliest inhabitants had to deal were such as might seem singularly unpropitious to the growth of a large and prosperous city. Their untillable and salt-encrusted soil possessed no kind of mineral wealth; the thickets which here and there diversified the surface of the barren marshes produced no serviceable timber; and even drinkable water was hardly obtainable; yet it was here that the Venetians by their inventiveness, their energy, their industry, and their genius for commerce succeeded in establishing themselves on a firm soil and maintaining their independence, in making their neighbors their tributaries, in sending their fleets to distant shores, in controlling the destiny of empires, and consolidating a naval power that is unique in the history of the world.

Maritime tribunes.

Doge.

War with Pippin.

The Venetian form of government—that of an aristocratic republic—had its first beginning at a very early period. Originally all power had been delegated to magistrates known as *tribuni maritimi* or maritime tribunes; but in 697, in order to give greater strength to the supreme power and more unity to the popular representation, a *doge* or duke was chosen, who had his residence in the little town of Heraclea. The first to bear this title was Paulucio Anafesto; the assembly by which he was elected consisted of the entire body of the inhabitants, not only of the towns on the mainland, which were constantly under fear of renewed barbarian devastations, but also those of the islets of the lagoons. Although all had equal electoral privileges, there were gradations of social rank, the citizens being divided into three classes—the *maggiori*, the *mediocri*, and the *minori*. The new arrangement lasted only forty years, when a general assembly resolved by acclamation on the abolition of the ducal power, for which was substituted that of the *maestri della milizia*, whose term of office was to last only for a year. The inconveniences of the new system, however, soon became apparent, and five years later (742) the assembly demanded the restoration of a single popular representative with life tenure, who again bore the title of doge. On this occasion the newly elected doge transferred his residence from Heraclea to Malamocco. The practical risks involved in the new experiment are obvious. In the succession of doges some were almost sure to show themselves unfit for the supreme power, others to disregard the authority of the auxiliary magistrates associated with them for purposes of control, and some even to aim at the establishment of an hereditary tyranny. Consequently the next sixty years witnessed a succession of bloody revolts, in the course of which three doges were put to death, one deposed and exiled, and several others condemned to lose their eyes. Nor was the incapacity or the ambition of individuals the sole cause of such revolutions: new circumstances as they arose sometimes compelled the doges by the very law of their existence to seek support outside the limits of the state, at one time from the Greek empire, whose frontier extended to their very doors, at another time from the Lombards, the latest invaders of Italy, who had permanently established themselves there and were daily acquiring new influence. Foreigners who, in connection with the interests of commerce, had entered into close relations with the Venetians took advantage of these to stir up troubles, and sought to conciliate the doges with a view to the enlargement of their trading privileges or the concession of monopolies. Between 712 and 810 various struggles arose which called for the intervention in the lagoons of the generals of Pippin and his son Charlemagne. Doge Obelerio, a declared partisan of the Franks, allowed a war to break out between the Venetians and the Lombards, in the course of which Pippin seized Grado, the see of the patriarch, burnt Caorle, Jesolo, and Heraclea, encamped in Albiola, and, forcing his way into the lagoon, threatened Malamocco itself (see map p. 166, below). Peace was afterwards concluded, and the danger to which the last refuge of the fugitives from the mainland had been exposed led to their increased security. For, whether from the instinct of self-preservation or from a growing consciousness of the idea of fatherland, these fishermen became drawn together more closely than ever for purposes of common defence, and found themselves possessed of a power hitherto unsuspected, so that they were able to compel their enemies to respect their independence and enter into commercial relations with them. The year 810 was one of the

Foundation of the city.

most important in the annals of Venice; it was then that the people finally abandoned the mainland in order to make the Rivo Alto with its surrounding islets the permanent seat of their government. The same year witnessed the beginnings of the basilica of St. Mark. Angelo Partecipazio, who had proposed the migration to the Rialto, was chosen doge, and the town of Venice may be said to have been then founded.

Early doges.

From 811 to 1026 there was a succession of eighteen doges, of whom no fewer than fifteen were selected out of three leading families, political power thus plainly tending to become hereditary. It was no uncommon thing, however, for the people again to dismiss those whom they had thus placed in power. Murder, exile, cruel punishments, closed the career of more than one of the doges who had been called to the supreme authority by a unanimous vote; whole families connected with rulers who had been deposed or put to death were compelled to quit the islands, and sought the help of the emperor Otho II. That emperor was preparing an expedition against Venice at the very moment of his death; and now once more the Venetians found safety in the very greatness of the danger which had threatened them, for the peril itself indicated to them the future at which they ought to aim if they would live and rule.

Suppression of Adriatic pirates.

Period of crusades.

From the necessities of its geographical position the new state was bound to become a maritime power and to look to the East. Towards the end of the 10th century the doge Pietro Orseolo by a vigorous effort cleared the sea of pirates, who dwelt on the eastern coast of the Adriatic and seriously harassed the Venetian commerce, and pursued them into the recesses of Quarnero and the islands of Istria. On 20th May, 998, having advanced as far as Dalmatia, he came upon them in their apparently inaccessible retreats, and inflicted upon them a great slaughter. Having thus given full security to trade, he constituted himself protector of the sea from Trieste to Albania, receiving in consequence the title of duke of Dalmatia. It was to symbolize this dominion that Venice instituted the superb ceremonial of the espousals of the doge with the Adriatic, which was annually observed on Ascension Day. The republic began henceforward to undertake the business of transporting to the East the successive armies of crusaders, to whom she lent on hire the fleets which were built in her arsenals; and these bold enterprises, at once religious, commercial, and military, procured for her in exchange important stations on the east of the Adriatic and in the islands, as well as colonies and factories advantageous for her commerce. The whole littoral from Trieste to Albania became in this way a sort of prolongation of the Venetian coast. The Byzantine emperors could hardly fail to become jealous of this great though pacific influence, and of the wealth thus created under their eyes and at their expense; and in the spring of 1171 Manuel I. ordered the sequestration of all Venetian goods and of all Venetians who had settled within the empire. Such a high-handed act at once called forth an outburst of enthusiasm, and the doge, Vitale Michieli II., sent out against Constantinople an imposing fleet to avenge the cause of the Venetian colonists. An outbreak of plague, however, on board the fleet compelled him to return to port; in so doing he brought the scourge to the town itself,—a disaster which led to his death at the hands of the infuriated populace. Even this catastrophe was not without its uses, for it led to the introduction of reforms fitted to give greater internal stability to the state.

Constitution of the State.

Under Sebastiano Ziani, Michieli's successor, the constitution underwent a further modification. The citizens, already divided into quarters (*sestieri*), nominated twelve electors, who in their turn made choice of forty picked citizens in each of the divisions of the city. The 480 thus chosen constituted the great council, a body possessing at once deliberative and executive functions. Before this period certain intimate councillors, two of them permanent, had been summoned to act as advisers of the doge in matters of importance; but now their number was increased and they were requested (hence the name *pregato*) to assist the head of the state in all circumstances. The two permanent councillors of the doge, increased to six and conjoined with the supreme magistrates on whom the administration of justice had always devolved, formed the lesser council, which afterwards came to be known as La Signoria. If we add, finally, to the powers already enumerated the council of ten, which was instituted later, and also take into account the increasing body of secretaries and the magistracies which were gradually created as need arose, we shall have an adequate conception of the perfected instrument of government by which the republic was controlled from the 13th century until its fall. While the political organization was thus rapidly developing, the change which was also passing over its democratic spirit must not be overlooked; the simple citizen gradually lost his privileges, and the increasing restrictions laid upon freedom ultimately made the government essentially aristocratic. Towards the end of the 13th century (1297) the important measure known as the "Shutting of the Great Council" (compare vol. xvii. p. 541), and subsequently the inscription in the Golden Book of the names of all branches of the noble houses, forever shut against plebeians every avenue to power. For a long time before this the right of electing the doge had been restricted to certain carefully selected citizens,—a constitutional change of capital importance, which had caused much discontent and raised such a ferment in the mind of the masses that the first doge who was thus chosen, realizing the danger of the situation, refused to accept the dignity. The number of the electors was consequently increased and the election made subject to a number of ballots intended to safeguard the integrity of the vote; but it remained none the less true that to the people had been left nothing more than the illusory light of approving by acclamation in the basilica of St. Mark each new doge after his election. The aristocracy, as it felt its growing force, proceeded to enlarge its powers, and did not fail to guard them down to the fall of Venice by constantly increased restrictions. It was not long, it is true, before the danger attaching to so great a power separated from the living forces of the nation was perceived, and there came to be instituted special kinds of magistrates, such as the "correctors of the ducal engagement," whose function was to revise the charter to which he was to swear, and who steadily exercised it in the way of restricting his freedom in such a manner that about the 16th century his lot was little better than that of a prisoner of state. Then there were the "examiners of the deceased doge," instituted in 1501,—posthumous judges whose verdicts on each departed doge on behalf of posterity still further conspired to neutralize the dangers arising from personal power.

Period of greatest prosperity.

The history of Venice was officially written by contemporary chroniclers. The records they have left are of course exceedingly valuable; but, as they were subjected to a rigorous censorship, the element of criticism is quite absent. Modern investigators, viewing the events from the outside, have been much more successful in forming a true judgment upon them and in tracing effects to their actual causes. Those Venetians who, since the fall of their republic, have endeavored to investigate its annals in an independent spirit have come to the conclusion that it was between the 12th and the 15th century that the state reached its highest prosperity and power. In point of fact, the republic had at the beginning of the 13th century become so powerful that the Byzantine empire fell into its hands through the conquest of Constantinople by the doge Enrico Dandolo (1204). The Venetians even sought to raise a Latin empire upon its ruins, but the attempt was frustrated by the jealousy of the rival republic of Genoa, which re-established the Greeks in 1261. The period between 1172, the date of the election of Sebastiano Ziani, and 1300, that of the election of Pietro Gradenigo, is one of the most brilliant in the history of Venice. The union that prevailed among all the citizens, the common effort of all classes, the military energy of the Government, the supple flexibility of its policy, had given them Constantinople; and the peace which they made with Palæologus on his restoration to the Byzantine throne brought them many splendid advantages. It was in virtue of these successes and in the midst of the internal peace which they had secured that Pietro Gradenigo proposed the "Shutting of the Great Council," a measure the importance of which can be traced throughout the subsequent history of the state. Its effect was to exclude from political power all who had not been members of that assembly during the previous four years; in a word, it constituted an hereditary legislature. Grave as the measure was, alternately accepted, rejected, modified, and never unopposed, it was finally carried. The new body enacted new laws and provided administrative heads for the ten departments of government,—justice, legislation, worship, finance, commerce, education, war, marine, public health, and city administration. The powerful and wealthy republic now found the honor of its alliance sought by emperors and popes; the standard of St. Mark was a familiar sight all over the Mediterranean; and ultimately Venice entered the "European concert." Now, too, she began to show that devotion to architecture and the fine arts generally of which the basilica of St. Mark's and the ducal palace are the most striking monuments.

Relations with the East.

Grown wealthy by commerce, and having acquired by the force of arms considerable territory on the east of the Adriatic, the Venetians now cast their eyes towards Asia. Their adventurous travellers had penetrated to the central regions of that continent, and Marco Polo on his return dazzled the populace by his wondrous tales and excited the cupidity of the merchants with visions of the riches of the East. New commercial enterprises were entered on; samples of Oriental industry with all their splendor of color and delicacy of pattern were brought home: glass, enamels, tapestries, silks, served as models to the deft artisans, who drew from them new inspirations and, re-discovering the secrets of the smith's and potter's and glassblower's art, reproduced the artistic triumphs of their Oriental masters. Nor were letters neglected: rich and ancient manuscripts were brought from Greece; a friendly asylum was offered to exiled men of genius and learning; and freedom of thought and intellectual independence began to be exercised.

Commercial genius of Venetians.

If Venice in the course of its history was able at one period or another to show its superiority in every field of activity, if at the same time it was able to show enduring stability in its institutions and a wealth and political power quite out of proportion to the smallness of its territory and the number of its subjects, it owed these in the first instance to its genius for commerce and to its maritime ascendency. This commercial genius led in the first place to the development of Venetian shipping, the growth of the arsenals, and large advances in the art of naval construction, and ultimately resulted in indisputable naval supremacy. The beginning of its fortune was in the salt trade, of which it had the monopoly throughout central Europe. Besides working the sources of salt which they had within their own territory, the Venetians rented those of their neighbors the Bolognese, and found access to the rock-salt deposits of Austria and Hungary; and in every instance where a treaty was made with a foreign power a clause was introduced reserving to Venice, whether as victor or as vanquished, the exclusive privilege of supplying this commodity. The arsenal of Venice, which still exists, was its palladium; the high organization of this establishment, the technical skill of its workmen, the specially selected body of the "arsenalotti," to whom the republic entrusted the duty of guarding the senate and great council, and its admirable discipline were for centuries the envy of other European powers. The enemies of the republic frequently made special efforts to destroy it by espionage and treachery. At the most critical period in its history, when it was engaged in its great struggle with the Turks towards the end of the 16th century, the arsenal regularly sent forth a fully equipped galley each morning for a hundred successive days. The power or decadence of the republic at each period may be measured by the extent of its building-yards and by the number of its workmen and seamen. Where an ambassador had once seen an imposing force of 200 galleys all fully equipped for sea, another two centuries later saw only 20 ships of war, 16 galleys and 2 galeasses. At the acme of its prosperity the arsenal employed 16,000 workmen; but a little more than a century afterwards, even at a time of war, that number had fallen to 2000, still further diminished in peace to 500.

The arsenal.

Conspiracies of the 14th century.

The 14th century is remarkable for a series of conspiracies, which the official historians have attributed to mere turbulence and malignity, but which no doubt had their main cause much deeper, in the position to which the masses had been brought by the political changes of preceding centuries. The conspiracy of Marino Bocconio in 1300, that of Bajamonte Tiepolo ten years later, a third in 1328, and finally that associated with the name of Marino Faliero (1355), without actually imperilling the existence of the state, compelled the great council to take measures against the recurrence of such movements, and resulted in the creation of the "council of the ten," that powerful and mysterious body the significance of which still continues to exercise the ingenuity of the modern historian. Of these four conspiracies the first three were certainly aimed at the restoration of popular rights; the fourth, on the other hand, arose out of an ambitious attempt to seize personal power. The legend of Marino Faliero is well known (see FALIERO). It would be difficult to describe exactly the functions of the council of the ten. Appointed merely provisionally in 1300 at the time of the conspiracy, to act as an inquisition, it was made a permanent body in 1335. Twenty years later the importance of the process against Marino Faliero led to an increase in the number of its members (*la zonta*), and thenceforward the ten, under the presidency of the doge (*il consiglio*), took cognizance of all matters, and their action extended over every department of government. It is a mistake to suppose that the council was merely an extension of the power of the aristocracy. It acted, on the contrary, as a check on the encroachments of the latter; and if it occasionally fell into culpable excesses, if sometimes it employed what might be called "stage" machinery, allying itself with informers, rewarding traitors, surrounding its deliberations with an air of mystery only too favorable to private revenge and too threatening to public security, and in fact becoming at one time plainly the instrument of tyranny, nevertheless its constant watchfulness over the interests of the state was not without advantages and compensations.

Council of ten.

Contest with Genoa.

As invariably happens, the threatenings of danger from without gave pause to internal sedition and served to unite more closely together the aristocracy, the people, and the middle classes. The Genoese could but ill endure the supremacy of their rivals in the Adriatic. Leaving out of account a few years of truce, from 1298, the year of the defeat of the Venetians by their rivals at Curzola, to 1379, when after various changes of fortune the complete destruction of their fleet by the Genoese at Pola allowed the latter to force a passage to the very heart of the lagoons, the struggle between the two maritime republics had gone on uninterruptedly. Never had Venice been nearer total destruction than after the disaster at Pola, but never also had the patriotism of her citizens expressed itself more clearly and unmistakably. The community of interest between all classes was fully realized: old men, women, and children flew to arms; all classes liberally contributed to the replenishment of the empty treasury; the precious things that had been brought from the East found their way into the melting pot, and even the altars were stripped. Doge Andrea Contarini, an old man of eighty, claimed the honor of leading an improvised fleet against the enemy, and Victor Pisani, a distinguished captain who had fallen under the suspicions of the ten, was brought up from his dungeon amid the acclamations of the whole people, who sacrificed every resentment to the ardor of their patriotism. Along with Carlo Zeno, just returned from the wars in the East, he gave spirit to the combatants, and drove the Genoese from Chioggia (on which they had seized). Venice was saved, and, grateful for the services rendered by certain families of the middle class who had ably assisted Pisani and Zeno, the great council added to its numbers thirty new members selected from those who had most distinguished themselves in the struggle.

Conquest on the main land.

The large extension of its territory on the mainland in the 14th century marks an important stage in the history of Venice. From being essentially a naval power, the republic now began to be an important continental one; and henceforward down to the 17th century it threw its sword into the balance on every occasion on which Italy was made the battle-ground of Europe. The fall of the Lombard kingdom, the struggles of the Ghibellines and Guelphs, and the personal exploits of the condottieri all urged Venice to take her part in the great movement, to widen her sphere of action, while fortifying herself against the dangers of her immediate neighborhood, and to issue from her lagoons and establish herself as a state on *terra firma*. Venice made herself mistress of Vicenza, Feltre, and Bassano in 1388; and with the help of Carmagnola, Gattamelata, and afterwards Alviano and Colleoni, Padua and Verona were added in 1405, Udine and Friuli in 1420, Brescia in 1426, Bergamo in 1427, Crema in 1449, Rovigo in 1484, and Cremona in 1499, and podestas were set over each of these provinces.

Danger from the Turks.

Meanwhile a new danger was arising to Venice out of the Turkish advance in Europe. The republic was compelled to live continually, so to speak, on the *qui vive*, perpetually on the defensive. Mohammed II. became master of Constantinople in 1453; in the following year the Venetians attempted to exorcise the plague by means of a commercial treaty; but not many years passed before hostilities broke out. The Turks were destined to become the hereditary and implacable enemies of the republic, and their attitude of hostility to cease only with the fall of the latter. And, except for one united effort towards the end of the 16th century by Spain, Venice, and the pope, which resulted in the victory of Lepanto (1571), the banner of St. Mark was almost invariably unsupported in its contest with the crescent. At Negropont (1470), Smyrna, and Scutari (1474) Erizzo, Mocenigo, and Loredano valiantly maintained the honor of their flag; but after a struggle of several years the Venetian possessions in the archipelago were lost and the proud city was compelled to cede Scutari (1479), Negropont, and Modone. Nor was this all; the geographical discoveries of the Portuguese and the Spaniards were about to inflict an irreparable blow on the maritime supremacy of Venice. Although the bold feats of Columbus and Vasco da Gama deeply stirred her enthusiasm, yet times had changed. New cares and new duties called her attention elsewhere; Venice could no longer concentrate all her energies upon her navy; having now become a territorial power, she had to watch her frontiers on every side, threatened by troublesome neighbors, now by the Malatestas, now by the Estes, the Bentivoglios, and the Borgias.

Continental struggles.

League of Cambrai.

Having entered into treaty relations with Florence, Milan, and the Vatican, she found herself continually involved in ceaseless struggles, which demanded the presence of her mercenaries now in the plains of Lombardy, now in the Romagna, sometimes even in the kingdom of Naples. At the close of the 15th century, after a forty years' dispute over the fragments of the Lombard kingdom, which had fallen into the hands of the condottieri, the Italians saw the Alps twice crossed by the French and their country turned into a European battlefield. The efforts of the Venetians to extend their possessions on *terra firma* along the Italian shore of the Adriatic and inwards towards Bergamo provoked the Italian captains who had founded hereditary dynasties to unite with the pope and the king of France in opposing their further progress. Thus arose the League of Cambrai, which brought the republic to the verge of extinction. Defeated at Gera D'Adda (Agnadello) in 1509, she was compelled to withdraw her armies, not only from the recently conquered territories, but also from those in which she had been established for more than a century, and she had even to release her own subjects from their oath of allegiance. She had passed through no such peril since the day of Chioggia in the struggle with Genoa, for she was now face to face with three formidable enemies,—the king of France, the emperor Maximilian, and the pope,—not to speak of numerous petty powers, her Mantuan and Ferrarese neighbors, who hoped for a share in the spoil. At this juncture the senate displayed all its adroit suppleness and all its energy; it recognized how necessary it was on such an occasion to show pliancy, to temporize, and be humble. A new league, formed against the very power which had initiated the first, proved the salvation of Venice: the king of France fell under the suspicion of his allies, who accordingly turned against him. The battle of Ravenna in 1512 and that of Marignano in 1515 changed the whole aspect of affairs; new combinations were formed; and the treaty of Noyon restored to the republic all the continental territory she had lost.

War with the Turks.

Nevertheless the commonwealth was not allowed to rest, but was compelled henceforth to live constantly on the defensive, on the one hand against the Turks, who were a standing menace, and on the other, watching every movement and enterprise of the Italian princes, who would not suffer her to remain neutral in their incessant conflicts. Neither under Pius V. nor under Philip II. was the combined assistance of the pope and the Catholic king of much assistance to Venice against Islam. From the peace of Noyon (1516) to the year 1571, the date of the battle of Lepanto, the republic was never able for a single moment to lay down her arms, but was constantly driven to renewed efforts, which could not fail to exhaust her more and more. One by one she lost all her colonies: at one time it was Corfu, at another the islands of the Ægean, at another Nauplia and Malvasia. Her podestas, provveditori, and ambassadors in their several departments displayed an energy and a patriotism to which there are few parallels in history: the names of Bragadin and of Marc Antonio Barbaro remain as abiding examples of disinterestedness and patriotic self-sacrifice. Born for the service of the state, her nobles were held bound to devote their energies to the republic from early manhood, and to give her the benefit of their strength and experience to their latest breath. About 1570 the Turks threatened the fleets of the Christian powers which ventured into the Adriatic; and the pirates of the Barbary coasts boarded the Christian galleys and carried their crews into captivity, where they were held at heavy ransom. The Spaniards, whose sway then extended to the African coast of the Mediterranean, were determined to put an end to these incursions; the popes for their part were always ready to do battle with the infidel and to league themselves against the enemies of Christendom; and Venice, who saw her colonial possessions falling from her one by one, could not refuse an alliance which seemed to promise the possibility of striking a grand blow by which her supremacy might be restored. On 13th May, 1571, the treaty of alliance between the three powers was signed; the league against the Ottomans was to be perpetual, and its avowed object was to destroy their influence. Philip II. agreed to pay half the expenses of the expedition; the republic supplied galleys to the pope; Spain contributed her fleets and demanded in return the chief command of the expedition. The total naval force numbered no less than 300 vessels, while the troops embarked were reckoned at 50,000 foot soldiers and 5000 horse. Don John of Austria represented Spain in the command; the papal forces were entrusted to Marc Antonio Colonna; while the Venetian senate nominated Sebastian Venieri to be its admiral. The result of the battle of Lepanto, 7th October, 1571 (see vol. xiii. p. 728), was apparently the complete destruction of Turkey's naval forces. But the mutual jealousies of the allied powers served to counteract the effects of the victory, and the peace which followed, instead of being advantageous to the victors, turned out much to their prejudice. The action at Lepanto had taken place in the beginning of winter; it was impossible, therefore, to undertake anything further before the spring of the following year (1572), and each of the powers believed its fleets secure in the ports where they had taken refuge, when, on the following May, the tidings reached Venice that the Turkish fleet which had been supposed annihilated was once more afloat. Don John had wintered at Messina; Colonna had returned to Civita Vecchia; while the Venetian fleet had cast anchor off Corfu. Before the scattered allies could reunite sixty Turkish galleys advanced through the archipelago and devasted the Venetian colonies. The Spaniards at Messina awaited the decision of Philip II. before they could set sail. The knights of Malta and the duke of Savoy, less hesitating, consented to join the Venetian galleys, and to go to meet the Moslems, whom they encountered at Cerigo. A battle of doubtful issue was about to be engaged in, when a message from Don John announced the co-operation of the Spanish fleet, but at Corfu, whither the Venetian admiral was requested to repair in order to concert a new plan of attack. The Venetians did not feel certain enough of success to warrant them in commencing hostilities without their ally, and, sailing for Corfu, they once more entrusted the supreme direction of affairs to Don John. But it is easy to understand how disastrous in their results such vacillation and hesitancy must necessarily be. It was not till the end of August that the allied forces, once more brought together to the number of more than 250 vessels, set sail in search of the Turkish fleet. The latter, being lighter, gave way before the enemy, and, avoiding a pitched battle, did not give opportunity even for a skirmish or the capture of a stray prize. Meanwhile the winter was approaching; navigation was becoming dangerous; the Spaniards were indisposed for action, and Don John, alleging the gravity of his responsibilies, returned to his anchorage at Messina. Thus a whole year had been lost, giving to the enemy daily opportunities of recuperation. Every day new differences and mutual recriminations arose among the allies, and at length the idea of a peace with the Turks began to be broached in the councils of the republic. Such a proposal, however unlooked for, was suggested by considerations of the most practical kind, and by a just appreciation of the resources of the Ottoman empire; and the resulting negotiations, which were secretly conducted, led to a treaty being signed on 15th March, 1573. By that treaty twenty years of peace were guaranteed to the republic; but it reversed the position of parties, and the vanquished of Lepanto now figured as victors. The Turks in fact were audaciously exacting, but their negotiations were ably conducted and were completely successful. The one place which they had lost, Sopoto, was restored to them, and Venice also consented to the definitive cession of Cyprus, which had temporarily fallen into her hands before Lepanto. Nor was this all: it was not forgotten that Venice was tributary to the sultan; her dues were doubled and a war indemnity of 300,000 ducats (gold, $680,400) was stipulated for. On the other hand, the commercial privileges hitherto enjoyed by the republic were confirmed, and the freedom of the seas was guaranteed.

Battle of Lepanto.

The epoch of Lepanto is, however, the most brilliant in Venetian history as regards the efflorescence of the arts and of literature; it was at this time that the artistic glory of the city was seemingly most brilliant and most developed, and exercised the greatest attraction for strangers. More closely viewed, the 15th century had attained in Venice, and the subject cities of the mainland, a higher degree of culture; architecture, painting, sculpture, and the minor arts were inspired by a sentiment deeper, more sincere, more elevated both in form and in idea; but the artists who arose between the middle of the 15th and the close of the 16th century had a natural disposition, with a touch of the sensual, better corresponding with the tastes of the people and with its artistic ideal, which aroused a greater enthusiasm and made their names more famous.

Arts and literature.

In literature and art Venice was the link between Italy and Greece. Its Eastern colonists learned the Greek tongue; and the fall of the Greek empire brought to them its banished men of science and letters, who taught in their university and introduced to the Venetians the works of the ancients. Guarino of Verona opened to them Xenophon, Strabo, Lucian, Orpheus, Arrian, Dio, Procopius, Diodorus of Sicily, and Plato. At the same time they made Oriental architecture their own, impressing on it the stamp of their special needs and national genius. The Arabs gave them the manufacture of gunpowder and glass, and taught them decorative art; and from Persia they learned to weave costly tissues; while their plastic arts retained a reflection of the sunny lands which, for geographical reasons, were the source of their riches and the chief object of their preoccupation. The architecture, the painting, and the sculpture of Venice are separately treated (see below). Nor must it be forgotten that the city welcomed from the first the art of printing, and stamped it with its own individuality. Venice, more than any other town, has the credit of having rescued from oblivion, by editions and translations, the masterpieces of Greek literature. The work of the elder Aldus in this direction from 1495 to 1515 has been spoken of in the article MANUTIUS (*q.v.*). The literary talent of Venice did not shine in works of imagination; but on the utilitarian side it was really great and original. In Venice history was written to order, and so is open to suspicion. In poetry, if we may cite Pietro Bembo, Molza, Berni, Lodovico Dolce, Doni, Niccolo Franco, Rucellai, Sperone Speroni, and L. Aretino, whom his contemporaries called *Il Divino*, as all Venetians or refugees claiming the greater freedom of thought which Venice then afforded, we must yet admit the lack of a name of world-wide significance, a Dante or a Molière. But the library of St. Mark's shows the respect of the republic for letters; the building that housed the MS. collections bequeathed by Petrarch and Cardinal Bessarion is, perhaps, the most perfect model of 16th-century architecture; and the librarian of the Marciana was, in virtue of his office, so high a personage that he had a title to be voted on by the senate and the great council for the ducal crown.

Condition at end of 16th century.

Such was Venice at the close of the 16th century, when some clearness of vision was still needed to foretell the approaching decay. She still had colonies, but their preservation became more difficult with the declining resources of the state. The customs were less productive, and the senate vainly sought to improve them by instituting at this period the "consuls of the merchants," the "provisors of commerce," the five "experts in exchanges." Manners, too, were degenerating into indolence and luxury, and the courtesans of Venice were more famous than those of Rome. The *proveditori alle pompe* were designed to check the dilapidations of young patricians on the wealth their ancestors had gained by trade, and the like wastefulness of plain citizens, who consoled themselves for their exclusion from public charges and honors by squandering in idle profusion the money gained by trading commissions and illicit pursuits.

If the old senators who had known austerer times were privately exercised by the perils approaching the state, they were careful in public to conceal its weakness and dazzle strangers by the splendor of their pomps and receptions, and the oriental gorgeousness of their palaces, churches, and processions, as was seen in the magnificent fêtes given in 1574 to Henry III. on his way to assume the throne of France.[1] They desired to make the king an ally as well as a guest, and some time later favorably entertained his proposal for a loan of 100,000 crowns [$125,000] of gold. In 1575 the city was visited by the plague, the almost inevitable consequence of such constant communication with the East. Forty thousand Venetians fell, and the scourge passed on to the mainland, which it ravaged for four months. Next year the doge Mocenigo died, and the election fell to the old sea-lion Sebastian Venieri, the hero of Lepanto, who already reckoned three "most serene princes" in his family. He ruled but two years, and his last days were marred by the conflagration of the ducal palace. His successor was Nicolo da Ponte, a graybeard of eighty-eight years, whose age showed that in the doge the Venetians sought rather the symbol than the reality of authority. Yet he reigned for seven years, full of peace and useful public works: the ducal palace rose from its ruins; the procurazie or offices for the guardians of noble orphans were completed; Palladio fulfilled the vow of the senate on the occasion of the late plague by erecting the marble bridge of the Rialto to replace the old wooden structure, and began the church of the Redeemer; and Corfu and the Friulian frontier were fortified.

The peace of Italy had been mainly due to the religious wars of France; but the senate had wisely sought and maintained the friendship of Henry III., and after his death, in 1589, had been sagacious enough to be the first of European powers to recognize Henry of Navarre, thus securing a vigorous ally against Spain, which had turned against the republic since the battle of Lepanto. The French alliance proved durable; Henry IV. mediated between Venice and the duke of Savoy, and on his marriage with Mary de' Medici his name was inscribed in the Book of Gold.

Rivalry between Venice and the pope.

The doge Pasquale Cicogna, elected in 1585, was succeeded in 1595 by Marino Grimani, whose rule was marked by grave dissensions between the senate and the Vatican. The house of Este came to an end in 1597, Pope Clement VIII. declaring Cæsar d'Este, the nephew of Alphonso II., duke of Ferrara, incapable of succeeding him. But Venice supported his claims and was ready to enforce them by war, when he ceded Ferrara to the pope, contenting himself with the dukedom of Modena and Reggio. This solution brought the Vatican into a permanent rivalry with Venice,—a grave matter, since at the beginning of the century Cæsar Borgia had seized the Romagna in the name of Alexander VI., and Julius II. had occupied Bologna, so that the Estates of the Church bordered on those of the republic. There were other causes of dissension also: Venice had never been on cordial terms with the Papacy; the recognition of Henry of Navarre had given umbrage at Rome; and, though peace was made for a time, the quarrel recommenced, and in 1606 Paul V. launched an interdict at the republic. Venice affected the greatest formal respect for the holy see; the legate sat by the side of the doge and took precedence of princes as well as ambassadors; but under all the forms of respect the extravagant pretensions of the popes were constantly repelled with inflexible firmness and energy. The ambassadors of Venice at Rome were always chosen from the most experienced and active men of affairs, and, though the pope had nearer relations with Venice than any other friendly sovereign, churchmen were constantly excluded from all political and civil posts in the republic. A man, it was held, could not serve two masters. Nay, in all discussions bearing on relations with Rome, whether in the senate or the great council, the usher's call "Fuori i Papalisti" excluded from the deliberations, not only patricians whose ties of family or interest bound them to the sacred see, but all who even held what would now be called ultramontane opinions. The Venetian clergy made no contribution to public burdens; the tithes required in time of war could be raised only by a special papal brief, and this privilege the senate claimed the right to suppress. To this Sixtus V. had consented; but his successor was less complaisant. In face of the new pretensions of the Vatican the Venetians multiplied restrictive measures against the clergy, and the conflict grew hotter on both sides, till Paul V. laid the republic under the interdict,—a step that still struck terror into nations. The hostile Spaniards were not without their share in this measure. But the supple Venetians made no appeal to temporal arms: they left the negotiation of the difficulty to theologians, and Paolo Sarpi made peace between Rome and the senate.

Conflict with Spain.

Scarcely was this trouble appeased when the Uskok pirates of the Adriatic coast and the Quarnero Islands recommenced their hostilities, and for ten years (1607–17) no merchant fleet could sail eastward without a convoy. The pirates were supported by Austria, which coveted Istria and Dalmatia, and the conflict was ended in 1617 by the treaty of Madrid between Venice and that power. Next year the Spanish conspiracy, originated by the Spanish ambassador, the marquis of Bedmar, broke out in the city itself, but was detected in time by the vigilance of the ten. The Spaniards meant to seize the arsenal by the help of some of the most influential senators. In 1622 Antonio Foscarini was disgraced because he was suspected of plotting with the Spanish ambassador; the Catholic king carried on his intrigues everywhere. But the republic on its part was not inactive and had stirred up against Spain a formidable enemy, the duke of Savoy, to whom in one year (1617) it lent more than a million crowns [$1,215,000.00] of gold. From 1627 to 1631 the two enemies were again face to face in the war of the Mantuan succession; but this time it was the duke of Savoy who made a peace to which Venice merely assented.

Peace was unbroken from 1631 to 1645. But in the latter year the Turks suddenly fell on the island of Crete; and for twenty-four years the whole forces of

---

Loss of Crete to Turkey.

the republic, and every thought of the people and the nobles, were concentrated on the preservation of this colony, which had been purchased from the marquis of Montferrat at the date of the fifth crusade, and in course of time had become a place of the first importance both as a trading station and a naval port. Surprised by the suddenness of the attack, the senate appealed to Europe for aid, and the Vatican, Florence, Naples, and the knights of Malta came to their succor; but after an alliance of thirty-seven days all the helpers regained their ships and left the Venetians to confront the enemy alone. The struggle was valiantly maintained and cost Venice, between 1645 and 1669, no less than 4,392,000 ducats [gold, $9,961,056.00]. The siege of Candia alone lasted twenty-two years, and for three successive years the combats were continual. At length, on 6th September, 1669, the Turks were masters of the island. Europe had looked on impassively at a struggle which, disastrous as was the issue, bore the highest testimony to the valor and patriotism of the generals of the republic. Biagio Giuliani, Tommaso Morosini, Jacopo Riva, Alvisio and Lazaro Mocenigo, Giuseppe Dolfin, and Lorenzo Marcello surpassed one another in exploits worthy of the heroes of antiquity. Between May and September, 1667, thirty-two assaults were delivered and repulsed before Candia, and seventeen sorties were made by the besieged. The glory of such a resistance did not compensate for the disaster, which reduced the public treasure of Venice from 6,000,000 [$13,769,220.00] sequins to 500,000 [$1,147,435.00]. (See also GREECE, vol. xi. p. 108.)

Morosini's Peloponnesian campaigns.

The troubles excited all over Europe by the ambition of Louis XIV. gave an interval of rest and recovery to the republic, which knew how to preserve its neutrality; and the years from 1674 to 1684 were a period of profound peace. But the enmity of the Turk still counted on the visible weakness of his rival, and imposed on her humiliations which her isolation and the exhaustion of her finances compelled her to submit to. Venice was only saved by the diversion produced by the siege of Vienna and the intervention of John Sobieski; but even then their repulse in central Europe sent back the Turks more determined than ever to be done with Venice and strip her of her whole possessions. At this crisis the senate called Francesco Morosini to the command of the fleet, a post in which he covered himself with glory by his bold offensive operations in the Peloponnesus. For fourteen years the contest was bravely maintained on both sides, but the fortune of war was against the Turks. The Venetians occupied the Morea and laid siege to Athens, Morosini bombarding the Parthenon, which had been made a powder magazine. The campaigns, renewed every spring, were marked by a series of victories: Prevesa, Navarino, Modone, Argos, Lepanto, Corinth, all added glory to the name of Morosini "il Peloponesiaco." He failed, however, in his attack on Negropont, after he had been raised (1688) to the dignity of doge. Conaro, who followed him in the command of the fleet, died suddenly; and then Domenico Mocenigo, the new commander, formed the bold project of retaking Crete, and was already before the port of Canea when the news of a Turkish attack on the Morea—really no more than a feeble diversion—induced him to raise the siege and lose his opportunity. The error cost him dear: he was removed from his command, and the old doge Morosini again took the field in spite of his seventy-five years, but soon succumbed to fatigue (1694), when Sylvester Valieri succeeded to the ducal throne. The war continued under the leadership of Antonio Zeno. Scio was taken and lost again; reverses followed on victories; and the stern senate removed the captain and the proveditori. But the peace of Carlowitz (1699) between Austria and the Porte brought with it the end of the war between Venice and the sultan, and the Turks, whose humiliation dates from this epoch, were compelled, besides their concessions to Austria, Poland, and Russia, to recognize the authority of Venice in the Morea and in Dalmatia as far as the Bosnian frontier.

The 18th century.

The first thirteen years of the 18th century, when almost all Europe was involved in the War of the Spanish Succession, were a time of repose for Venice, which remained neutral; but hardly was the peace of Utrecht concluded when the Turks resumed the offensive against the republic, which now had no allies. One after the other the islands and colonies ceded by the peace of Carlowitz were retaken; the Morea again became Turkish; Dalmatia was saved only by the interposition of Austria, which had need of the friendship of Venice to checkmate the projects of Philip of Spain against the Italian duchies. But soon the emperor found it necessary, in view of the struggle with Spain, to come to terms with the sultan; and his allies, the Venetians, were included in the peace of Passarowitz signed between Austria and Turkey on 21st July, 1718. From this moment Venice ceased to have any influence on European politics: she had no more wars, if she still had enemies, signed no more treaties, and, in a word, had abdicated her place in Europe. Not even the dispute of 1731 as to the succession to the duchy of Parma, which brought France, Austria, Spain, and Savoy into conflict at her very doors, stirred her to action; she was indeed no longer a useful ally. Her navy had fallen behind the times; her commerce had been in decadence since the way to the East by the Cape of Good Hope was opened; she could scarcely repulse the Barbary pirates from her shores; and she had to treat with Algiers, Tunis, and Morocco to put an end to their inroads, daily repeated from 1760 to 1774. Yet, the Tunisians failing in their engagements, she decided on a war with them, which was closed by a fresh treaty.

Constitutional reforms.

The government meanwhile went on in the old form. The successive doges were still tied by the restrictive laws which made them crowned prisoners; but rivalries sprang up between the great powers of the state: the senate attacked the institution of the *savii*, the ministers delegated to each branch of the administration, and in turn the magistrates known as the *quarantie* proposed to reform the senate, while, lastly, the council of ten was threatened by the great council. In the midst of these reforms, which were calculated to make a great change in the institutions of Venice, the French Revolution broke out. Ludovico Manin had just become doge (1788), but was a mere cipher in the councils of the state. No heed was paid to the information supplied by the ambassadors of Venice at the court of France; nothing was foreseen, nothing decided on, for neither senate nor council understood the vast sweep of the new movement in Europe.

Napoleonic period.

Soon the Venetians were called on to recognize the French republic; they refused, but did not join the coalition against it. When Bonaparte was at the gates of Mantua, they at length decided to treat with him; but it was too late. Mantua capitulated on 2d February, 1797; the Venetian envoys presented themselves before Bonaparte on 25th March; and on 18th April the Austrians signed the peace of Leoben, which left Venice without an ally at the feet of the victorious invaders of Italy. On 8th May the great council decided to offer no resistance to the French; the doge abdicated on the 12th; and Napoleon entered the city on the 16th, and proclaimed the end of the republic. On 17th October following Bonaparte, by the treaty of Campo Formio, abandoned the territory of Venice to Austria. Venice was buffeted to and fro between France and Austria from 1798 to 1814, when the new coalition assigned her to Austria. Till 1866 Venice remained Austrian, save for a few hours in the insurrections of 1848–49; but her people never acknowledged the rights of those who had bought and sold them like a flock of sheep. The war between Austria and the allied Prussians and Italians in 1866 gave Venice her freedom, and the unity of Italy was at length accomplished under the sceptre of the house of Savoy (see ITALY, vol. xiii. p. 501). (C. Y.)

PART II.—ART.

Architecture.

Early state.

For some centuries Venice must have consisted mainly of a few groups of wooden huts scattered among the many small grassy islets that lay off the coast of Venetia. At first the main occupations of the inhabitants were fishing and preparing salt by evaporation. But, as they grew richer, especially through the possession of large numbers of coasting vessels, in which they transported the merchandise or troops of foreign races at what were frequently very remunerative rates,[1] they became exposed to the inroads of Dalmatian pirates; and strongly defended castle-like houses began to be built in stone or brick, with towers at the angles and battlements all along the walls. Though no example exists of these early Venetian castles, a very interesting survival of their general form is still to be traced in the 11th and 12th century palaces, of which a considerable number are yet to be seen (see Fig. 5 below). As the city increased in size and importance, great changes were made in the form of the islands on which it stands and in the network of salt water channels which divided the smaller islands from one another. In the 13th and 14th centuries many decrees of the great council provided for the deepening of existing canals, for filling up others, for draining marshes and forming dry ground by bringing shiploads of soil from neighboring islands, and for driving piles to form securer ground for building. The shallow salt lagoons which surround the islands of Venice form a long band, 4 to 8 miles wide, once reaching to the Roman cities of Ravenna on the south and Aquileia on the north.[2] These waters, averaging only 1 to 4 feet in depth, are separated from the deep sea by a series of long, sandy island bars. Those which form the natural breakwater to Venice are called Malamocco and Lido.

Bridges.

The early bridges of Venice were wooden structures; even that over the Rialto was of no more durable material till the present bridge was built in 1591. Many were mere planks nailed on boats. One of the earliest built in stone was that by the southeast angle of the ducal palace, called the Ponte della Paglia, which was founded in 1360. Its name ("the bridge of straw") appears to be due to the fact that it was built with money from the tax on straw,[3] large quantities of which were used to thatch the early houses of Venice. Till about the middle of the 19th century the Rialto was the only bridge across the Grand Canal.

Early churches.

According to tradition, the first church built in Venice was S. Giacomo del Rialto (founded in 432).[4] The legendary history of the founding of some other early churches is given in the *Chronicle* of Andrea Dandolo, written *c.* 1350. In the 5th century St. Magnus, bishop of Altinum, who included in his see the Rialto and adjacent islands, had the following series of visions. (1) St. Peter appeared and bade him found a church on that island where he should find oxen and sheep grazing; and on the little island of Olivolo, at the extreme east of Venice, he accordingly built the church of S. Pietro di Castello, which from 1091 till 1807 was the cathedral church of the Venetian patriarch. (2) The church of S. Raffaello in dorsoduro was founded in obedience to the archangel, who bade St. Magnus build a church at the place where he should see a large flock of birds. (3) St. Salvador was founded at the place where Christ told the bishop he would see a red cloud rest. (4) S. Maria Formosa was erected at the command of the Virgin, at the place where St. Magnus saw a white cloud resting. (5) S. Giovanni in Bragola (or Bragora) and S. Zaccaria were built in obedience to the Baptist, who told the bishop to raise churches to himself and his father. (6) The twelve apostles ordered a church to be built at the place where Bishop Magnus should see a flight of twelve cranes. (7) S. Giustina, in the last vision, bade the bishop build a church in her honor at the place where he should see vines laden with grapes. Other early churches were those of S. Geminiano and St. Theodore, both on the island of Rialto (see below, "St. Mark's Church").

Architectural styles.

Architectural Styles.—Owing to its isolated position on the verge of Italy, and its constant intercourse with the eastern shores and islands of the Mediterranean, Venetian architecture was an independent development, though with many Oriental characteristics, having a character of its own quite unlike the styles employed in other Western countries. It was a very complex growth, in which the most diverse styles were absorbed and blended together in a very beautiful way. The various strands which, woven, as it were, together, combined to form the magnificent web of Venetian architecture were chiefly these,—(1) the Byzantine, itself a most complex mixture of older styles, blended together and vivified with new life in the hands of the skilful builders and craftsmen of Justinian's time; (2) the Moslem as developed in the gorgeous mosques and palaces of Persia, Syria, and Egypt; (3) the Gothic of northern Europe, and especially of France, with a secondary strain of Florentine influence, which, however, was more marked in the sculpture than in the architecture.[5]

Byzantine.

In the 11th and 12th centuries the Byzantine style was universally employed by the Venetians. The arches of this period are semicircular, usually much stilted. The sculptured ornament is of very great beauty, and is applied freely round arches, along string-courses, and in panels, with which the external façades were often thickly studded. According to the peculiar Venetian system of decoration, the walls were built in solid brick-work and then covered with thin slabs of rich and costly marbles. The columns, with their capitals and bases, were, as a rule, the only places where solid blocks were placed. This constant method of facing with thin slabs necessitated the use of special forms of mouldings and carvings, and thus, except in the solid capitals, no deep cutting could be employed; therefore the mouldings of this period consist of small rolls, *cavettos*, or flutings contrived to enrich the surface with the least amount of cutting into the thin marble.[6] In the same way the sculptured bands are shallow in treatment, but full of the most vigorous grace, combined with the utmost spirit, in every line and curve, and rich, with an extreme delicacy, in all the details. Flowing scroll-work of semi-conventional foliage, mingled with grotesque animals, birds, or dragons, is most commonly used. As purely decorative sculpture, nothing could surpass the beauty of these early bands and panels. The round or arch-shaped or rectangular sculptured panels, used to stud the façades like rows of jewels, are of peculiar beauty and interest. Many of the designs are derived from the far East, and appear to be of Sasanian origin; favorite motives are eagles or dragons devouring hares or other animals, and peacocks treated in a conventionally decorative way, with their spreading tails forming a halo-like background to the body of the bird. Many of these panels are derived from the very ancient Assyrian subject of the sacred tree between two guardian beasts or birds; a common variety of this has two peacocks face to face drinking from a cup placed on a tall, pillar-like object, which recalls that on the lion-gate of Mycenæ. Many of these reliefs closely resemble the sculptured screens and altars of the 6th century in Ravenna, and are probably of the same date, though used to decorate buildings not earlier than the 12th century. The church of St. Mark, especially, is a rich storehouse of these examples of early sculpture. Others of exactly similar style, which exist in the churches of Thessalonica and other Eastern cities, bear witness to the unity of early Byzantine art and its wide geographical range until the downfall of the Eastern empire. One striking feature in Venetian architecture of all dates down to the 15th century is the constant use of the dentil moulding. This consists of a simple series of notchings, at once the easiest and the most effective way of enriching the thin facing-slabs when their *edges* were allowed to appear, as, for example, in those which lined the soffits of arches.

Moslem.

The influence of Moslem art is seen in the occasional use of the horse-shoe arch, in the very common ogee form which was almost universal in Venice from the 13th to the 15th century, and still more clearly in the fantastic rows of battlements, formed of thin pointed slabs of marble set on edge, which crowned the walls of nearly all the chief palaces of Venice in the 14th and the 15th century.

---

[1] There are many curious analogies between Venice in the early part of its career and the Phœnician city of Tyre in the 8th and 7th centuries, B.C., in the position of the two cities, their mercantile habits, their custom of acting as carriers for other races, and their both being in their habits of life and in their artistic productions links between the East and West.

[2] Vitruvius (i. 4) speaks of the lagoon cities of Aquileia, Altinum, and Ravenna as being healthy sites in spite of their position. Aquileia and Altinum, which were wealthy cities, were both destroyed by Attila.

[3] In the same way old London bridge was paid for by the wool duty.

[4] The word "Rialto" appears to have been applied, first to this deep channel of salt water, and secondly to the large adjacent island, that on which St. Mark's and the ducal palace are built.

[5] See E. A. Freeman, *Subject and neighbor lands of Venice.*

[6] See sections of mouldings illustrated by Mr. Ruskin in *Stones of Venice*, vol. iii., pls. v.–xi.

Gothic. The 13th century was the time of transition from the round arched Byzantine style to the pointed arch with tracery, which in some cases was derived directly from the Gothic of northern countries. This is seen especially in the two great churches of the Dominican and Franciscan friars, SS. Giovanni e Paolo and S. Maria Gloriosa dei Frari. These two stately churches resemble those built by the friars in other places in Italy,[1] and have little of the distinctively Venetian character of the contemporary domestic buildings. In the 14th and 15th centuries one peculiarity of Venetian Gothic is the way in which tracery is used to fill rectangular and not arched openings. The result of this is that the tracery itself has to support the mass of wall above it, whereas in the Gothic of other countries the tracery is merely, as it were, a pierced screen filling in a constructional arch, which carries the whole weight of the superimposed wall and roof. Hence the Venetian tracery, of which that in the upper story of the ducal palace is a typical example, is much thicker and heavier in construction.

Early Renaissance. In the latter part of the 15th century Venetian architecture began to lose its distinctively local character, though very beautiful examples of Early Renaissance were built by the Lombardi family and other architects, largely under the influence of Fra Giocondo (see VERONA).

Classic. In the 16th century, under the later development of the Renaissance, the Pseudo-Classic style was paramount in Venice, and Sansovino, Palladio, and others designed many costly buildings which had nothing specially Venetian in their style. This magnificent but dull and scholastic form of architecture reached its highest development in Venice, where it was later in degenerating into tasteless decadence than was generally the case elsewhere. Even in the 17th century good models of the Revived Classic style were built, especially by Longhena (see p. 168 below). After that the degradation of architecture and sculpture took place with great rapidity.

The periods of these styles may be roughly tabulated thus: (i.) Byzantine, 7th to end of 13th century; (ii.) Gothic, middle of 13th to *c.* 1460; (iii.) Early Renaissance, *c.* 1450-1520; (iv.) Classic, *c.* 1520-1620; (v.) Extreme Decadence, *c.* 1600 downwards.

Materials and Methods of Construction.—**Foundations.** In spite of its position on a number of small sandy islands in the lagoons, Venice was built upon firm and solid foundations, so that very few houses have suffered seriously from settlement. At a depth of 10 to 16 feet there is a firm bed of very stiff clay, and below this a bed of sand and gravel, and then a thin layer of peat. Recent borings for Artesian wells to a depth of about 1500 feet have shown a regular succession of these beds—clay, gravel, and peat—repeated again and again as far down as the borings have reached. The process implied in this geological formation seems still very slowly to be going on, and the present level of the square of St. Mark has been raised artificially about 20 inches above the old brick paving shown in Gentile Bellini's picture of 1496. A good example of the old method of forming foundations is shown in that of the great campanile of St. Mark, *c.* 900 (see Fig. 1). Here the builders dug down to the bed of stiff clay, and over the whole area of the footings of the tower drove in piles of white poplar, 10 to 11 inches in diameter, nearly touching one another. On the top of these a level platform was formed by two layers of oak trees (*Quercus robur*), each roughly squared, the upper layer being laid crosswise upon the lower one. The oak and poplar both grew along the shores close to Venice; in later times, when the Venetian territory was extended, the red larch (*Pinus Larix*) of Cadore and the Euganean Hills was largely used, as, for example, in the foundations of the ducal palace. In 1885 the foundations of the campanile were examined, and both the oak and the poplar were found to be perfectly sound.[2] On the wooden platform massive footings are laid, consisting of five courses of large blocks of trachyte and other granitic or porphyritic rocks from the Euganean Hills. Above these are six courses of similar stone arranged in step-like offsets, forming a base or plinth to the tower; owing to the raising of the pavement level only two and a half of these offsets are now visible. Another way of forming foundations, which was used in rather later times, was to omit the piles altogether and build footings with a wider spread. Fig. 1, which also shows the foundations of the ducal palace, dating from the 14th century, is a typical example of this second method, in which the oak platform is laid immediately on the stiff clay. The use of trachyte for foundations was soon superseded by that of Istrian limestone, a very beautiful cream-colored stone, extremely fine and close in texture and capable of receiving a very high polish. Though not crystalline in grain, and, technically speaking, not a true marble, this Istrian stone has for most architectural purposes all the beauty of the finest white marble, and receives from age a beautiful golden-russet patina, very much like that assumed by Pentelic marble. From the 11th century onwards it was used very largely for plinths, angle quoins, string-courses, window tracery, and other decorative purposes. It occurs, for example, in all the magnificent series of arcades in the ducal palace. Its extreme fineness of grain allows it to be worked with an ivory-like delicacy and minuteness of detail.

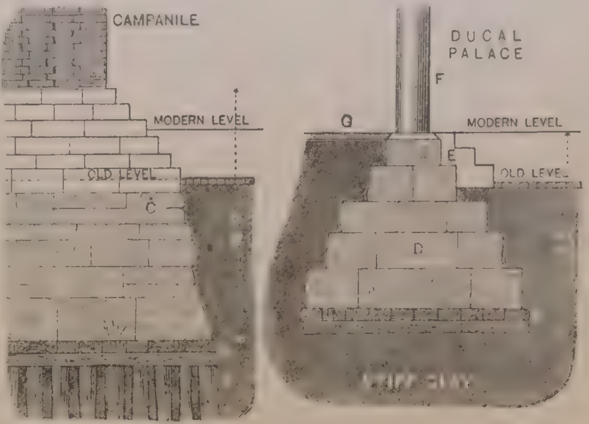

FIG. 1.—Two methods of forming foundations, one with piles the other with wider footings and no piles, as exemplified in the campanile and the ducal palace. A. 10-inch piles of white poplar, closely driven into the stiff clay. B.B. Double layers of oak planks, the same in both. C. Rough footings of campanile, made of trachyte and other volcanic stones. D. Similar footings under pillars of ducal palace. E. Stylobate of three steps, under lower loggia of palace, now hidden by raised level of modern pavement. F. One of the Istrian stone pillars of the palace. G. Paving of loggia, now flush with that outside.

Main walls. Throughout the Middle Ages the main walling of Venetian buildings was always of fine brick, usually a rich red in color, made and fired in the kilns of Murano. In spite of its beautiful color the brick-work was seldom left visible, the whole wall-surface being lined with thin slabs of marble in the more magnificent buildings, or else coated with stucco, on which diapers and other decorative patterns were painted.

Mortar. Before 1405 the mortar used in Venice was made of the white lime from the Istrian limestone, which possessed no hydraulic qualities, and was consequently very perishable. But after that year, when the Venetians conquered Padua, they were able to get supplies of a strong hydraulic dark lime from Albettone, which formed a very durable cement or mortar, able to resist salt water and the destructive sea air.

Marbles. One of the chief glories of Venice depends on its extensive use of the most beautiful and costly marbles and porphyries, which give a wealth of magnificent color such as is to be seen in no other city in the world. In early times none of these seem to have been obtained direct from the quarries, but from older buildings, either of Roman or early Byzantine date.[3] Immense quantities of rich marbles were brought from the ruined cities of Heraclea, Ravenna, Altinum, and especially Aquileia. Under the Roman empire Aquileia contained great numbers of magnificent buildings, decorated with marbles and porphyries from Greece, Numidia, Egypt, and Arabia. The gorgeous churches and palaces of the Byzantine emperors, enriched with rare marbles stolen from Greek and Roman buildings of classic times, were in their turn stripped of their costly columns and wall-linings by the victorious Venetians. Thus Venice became a magnificent storehouse in which were heaped the rich treasures accumulated throughout many previous centuries by various peoples. The principal varieties used in the palaces of Venice are—the red porphyry of Egypt and the green porphyry of Mount Taygetus, red and gray Egyptian granites, the beautiful lapis Atracius (verde antico), Oriental alabaster from Numidia and Arabia, the Phrygian pavonazzetto with its purple mottlings, cipollino from Carystus, and, in great quantities, the alabaster-like Proconnesian marble with bluish and amber-colored striations.[1] Till the 14th or 15th century the white marbles used in Venice were from Greek quarries—Parian or Pentelic—being all (like the colored marbles) stolen from older buildings, while in later times the native marble of Carrara was imported. Large quantities of red Verona marble were used to form moulded frames round panels of white sculptured marble. The greater part of these costly marbles seems to have been imported in the form of columns, immense numbers of which were sawn up lengthways into long thin slabs for use as wall-facings. Other columns, usually those of the most precious marbles, were sawn across, and thus the roundels were produced which stud like jewels the façades of many of the palaces (see Fig. 6). Thin slices sawn from the same column were reversed and placed side by side, so that the natural mottlings formed a regular sort of pattern. Very rich and complicated designs were produced by placing four slabs together to form one large pattern, repeating from one centre. The whole interior of St. Mark's is decorated in this magnificent way, very large areas being covered with the same pattern recurring again and again. Thus no attempt was made to disguise the fact that the marble was only a thin surface decoration of no constructional importance. The fact that many slabs had been cut from one block was frankly acknowledged by the formation of these "cut and reversed" patterns, nor is there any attempt to conceal the bronze clamps which hold the slabs in their places.

---

[1] Comp. S. Maria Novella and S. Croce in Florence and S. Maria sopra Minerva in Rome.

[2] An interesting account of this and other foundations in Venice is given by Giacomo Boni in the *Archivio Veneto*, ser. ii., vol. xxix., pt. ii. 1885.

[3] Early in the 15th century the Venetians began to work the rich quarries of red marble near Verona: but with this exception the decorative marbles seem to have been taken from older buildings elsewhere.

Gold and color decoration.

The façades of the chief palaces of Venice down to the end of the 15th century were wholly covered with these magnificently colored marbles. But that was not all; a still greater splendor of effect was given by the lavish use of gold and color, especially the costly ultramarine blue. Very frequently the whole of the sculpture, whether on capitals, archivolts, or frieze-like bands, was thickly covered with gold leaf, the flat grounds being colored a deep ultramarine so as to throw the reliefs into brilliant prominence. The less magnificent palaces were decorated in a simpler way. The brick surfaces between the windows and other arches were covered with fine hard stucco, made, like that of the ancient Romans, of a mixture of lime and marble dust. The whole of this was then decorated with minute diapers or other geometrical ornament in two or three earth colors, especially red, yellow, and brown ochres. Very few examples of this form of decoration still remain, owing to the corrosive action of the sea air. One notable example, dating from the 14th or 15th century, has a rich pattern formed by a series of adjacent quatrefoils, with half-figures of cherubs in the intermediate spaces, covering the whole flat surface of the wall. A few faded patches are now all that is left.

Frescos.

With the early years of the 16th century and the later development of the Renaissance totally different methods of architectural decoration superseded the use of precious marbles and delicate repeated ornament in color. The Pseudo-Classic buildings of Sansovino, Palladio, and their schools were either built of white stone or marble, quite unrelieved by color, or else stuccoed façades were treated simply as a ground on which to paint large frescos with figure subjects, not designed with any sense of the true principles of architectural decoration. These frescos, which covered the otherwise unornamental façades of many of the 16th-century palaces, were often the work of the greatest painters, from Giorgione to Tintoretto; but the pictures, though no doubt beautiful in themselves, were quite obviously out of place on the façade of a house: the colossal groups dwarfed the building they were painted on, and were far inferior in decorative effect to the simpler patterns of earlier times. These, too, have mostly perished: on the *fondaco*[2] of the Germans, once covered with frescos painted jointly by Titian and Giorgione, only traces of two figures now remain. One of the best-preserved series of these exterior frescos is that inside the cloister of S. Stefano, painted by Pordenone, which has naturally suffered less than the very exposed façades on the Grand Canal.

St. Mark's.

Church of St. Mark.—This church stands quite alone among the buildings of the world in respect of its unequalled richness of material and decoration, and also from the fact that it has been constructed with the spoils of countless other buildings, and therefore forms a museum of sculpture of the most varied kind, nearly every century from the 4th down to the latest Renaissance being represented in some carved panel or capital, if not more largely.

Site.

During the early years of Venetian history the site of the present church and square of St. Mark was a large grassy field, with rows of trees, divided by a canal (which no longer exists), and containing two churches. One of these, dedicated to St. Theodore, the old patron saint of Venice, stood on the site of the present church of St. Mark. The other, that of St. Geminiano, was a little to the northwest of the great campanile. Fig. 3 (below) shows its position, and also the site on which it was rebuilt by Sebastiano Ziani (1173–79), when he pulled down the original church in order to extend the square westwards. In the 16th century it was again rebuilt by Cristoforo del Legname and Sansovino, and was destroyed in 1805 by Napoleon I., to make room for a new block to unite the two palaces of the procurators. The grassy *campo* where these churches stood was the property of the abbey of S. Zaccaria. At its eastern extremity a small palace was built for the doge about 810, when Venice first became the chief ducal place of residence under Angelo Partecipazio.

Original chapel.

Older church.

According to the chief early chronicles, the body of St. Mark was secretly brought away from Alexandria and carried to Venice in 828, the church where he was buried having been pulled down by the Moslems in order to build with its materials a palace at "Babylon," as old Cairo was then called. After the arrival of his relics, St. Mark became the patron saint of Venice in place of St. Theodore, and his bones were laid in the "confessio" of the small private chapel of the ducal palace.[3] This chapel, however, soon lost its private character and became the chief church of Venice, though not the cathedral church of the patriarch. The small ducal chapel of St. Mark was burnt in 976, together with the rest of the palace, during the insurrection against Doge Candiano IV.: it was rebuilt on a larger scale by his successor, Pietro Orseolo, and the following doges, the work being carried on for about a century. An inscription now lost recorded its completion in 1071, but it was not consecrated till 1085, in the reign of Vitale Faliero (1084–1096), when it was dedicated "to God, the glorious Virgin Annunciate, and to the protector St. Mark." The form of the church as then completed was quite different from its present aspect, both in extent of plan and in absence of rich decoration. Fig. 2 shows the size of the older church, which was originally of the simple basilica form with three eastern apses and no transepts.[4] One very interesting relic of the old ducal palace still exists, namely the lower part of one of its towers, with walls 11 feet thick; this was made into the treasury of St. Mark when the church was enlarged so as to include it in its plan, at the west corner of the south transept. Recent processes of "restoration" have shown the external design of this early church, which was of plain red brick, undecorated by marble or mosaics, and only relieved by very simple blank arcading, with round arches, not unlike those on some early Norman buildings in England.[1]

---

[1] The splendid columns of St. Mark's, which Mr. Ruskin in the *Stones of Venice* speaks of as being of alabaster, really are of Proconnesian marble, and are so described by various early Byzantine writers. According to Vitruvius (ii. 8), the magnificent palaces of Crœsus of Lydia and Mausolus of Halicarnassus were chiefly adorned with Proconnesian marble.

[2] The word *fondaco*, of Arab provenance, from the Greek πανδοχεῖον, applied to several of the largest Venetian palaces, denotes the mercantile headquarters of a foreign trading nation. The *fondachi* of the Turks and of the Germans still exist, though much modernized. An analogous establishment was the *hellenium* of the trading Greeks at Naucratis in the Egyptian delta, remains of which have recently been discovered by Mr. Flinders Petrie (see *Proceedings of the Egypt. Explor. Soc.*, 1886).

[3] There is much analogy between the relationship of the church of St. Mark to the ducal palace and that of the abbey church to the royal palace at Westminster: both were originally built in connection with royal palaces and both possessed special privileges as "royal peculiars."

[4] T. G. Jackson, in his work on *Dalmatia and Istria* (Oxford, 1887), vol. iii., gives an interesting account and valuable illustrations of the early churches at Parenzo, Grado, and Aquileia, which in their sculptured capitals, mosaics, and other details closely resembled the early portions of St. Mark's. Large quantities of the sculpture and rich marbles used in Venice were brought from Grado, Aquileia, and other cities in the same district, the buildings of which were to a great extent the prototypes of those built in Venice before the 13th century. In later times the flood of influence passed in the opposite direction, and during the 14th and 15th centuries an immense number of palaces and churches were built in the Venetian style, by architects from Venice, all along the eastern shores of the Adriatic. The result is that in these Istrian cities examples are to be seen of what appears to be the architecture of Venice during its whole course of development from the 12th to the 15th century.

By degrees the church was enlarged: first of all transepts were added, then the baptistery on the south and the atrium extending along the west and north of the nave, about 1150–1200. Next chapels were added north and south of the two transepts: that of St. Isidore was built and finished in 1354 by Andrea Dandolo. In the 15th century the sacristy at the east end was added, the altar of St. Peter in the north apse being removed to make a passage to it; another way to the sacristy for the use of the clergy was cut through the massive wall of the main apse. During the long period from its dedication in 1085 till the overthrow of the Venetian republic by Napoleon every doge's reign saw some addition to the rich decorations of the church—mosaics, sculpture, wall linings, or columns of precious marbles. By degrees the whole walls inside and outside were completely faced either with glass mosaics on gold grounds or with precious colored marbles and porphyries, plain white marble being only used for sculpture, and then thickly covered with gold. It is impossible here to give an adequate notion of the splendor of the whole effect; nothing short of the eloquence of Mr. Ruskin can do justice to the subject.[2] Unfortunately the whole wall surface of the interior is so stained and caked with dirt that much of the gorgeous effect of the marbles is lost.

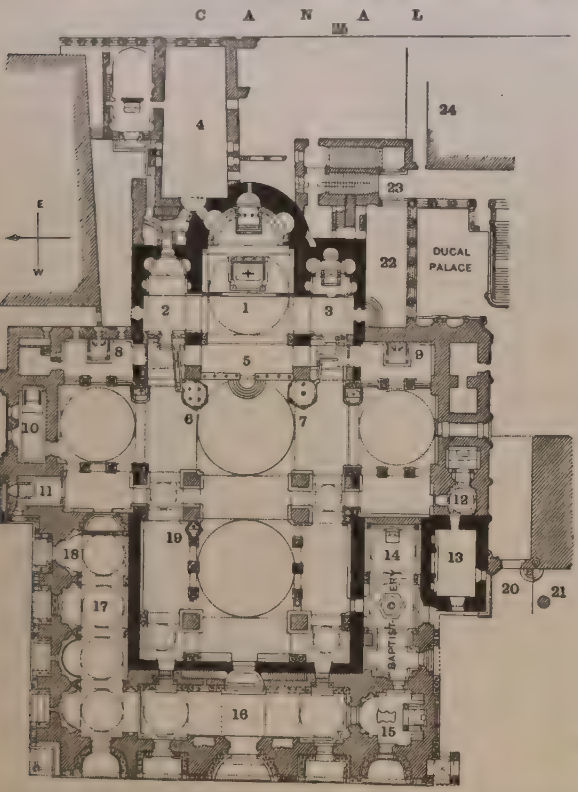

FIG. 2.—Plan of St. Mark's; the black shows its older form, the shading its later development. 1. High altar, containing the body of St. Mark. 2. North apsidal chapel of St. Peter. 3. South chapel of St. Clement. 4. 15th-century sacristy. 5. Rood-screen. 6. North ambo and patriarch's throne. 7. South ambo. 8. Altar of S. Maria dei Mascoli. 9. Altar of St. Leonard. 10. Chapel of S. Isidore, added in 1353–55. 11. Chapel of St. John the Evangelist. 12. Ante-room to treasury. 13. Treasury, formerly a tower of ducal palace. 14. Baptistery. 15. Chapel of Cardinal Zeno. 16. Grand staircase of palace. 24. 16th-century part of ducal palace. 25. Canal, Rio del Palazzo.

Decoration.

The general scheme of decoration is the following. The whole of the domes and vaults, and the upper part of the walls down to the level of the floor of the triforium, are completely covered with mosaics of brilliant glass tesseræ, the ground being in most cases of gold. Below this every inch of the surface of the walls and arches is covered with richly colored marbles, porphyries, and alabaster, relieved by pure white marble, sculptured in panels, string courses, and the like. The various marbles are arranged in broad upright bands, alternating so that one color enhances the effect of that next to it. For example, the nave wall in the north aisle is faced thus,—(1) verde antico, (2) Proconnesian, (3) red broccatello of Verona, (4) Proconnesian, (5) magnificent Oriental alabaster, (6) Proconnesian, and (7) verde antico; below these is a narrow band of red Verona marble, and then a plinth-moulding of Athenian white marble, which rests on the seat of panelled red marble that runs all round the interior of the nave and transepts. The large columns between the brick piers, six in the nave and eight in the transepts (see Fig. 2), are monoliths of fine Proconnesian marble, veined with grayish blue and amber, and the great brick piers are faced with thin slabs of the same material. This facing and most of that throughout the church are made of ancient columns sawn into slices.

Crypts.

The eastern crypt or confessio extends under the whole of the choir behind the rood-screen, and has three apses like the upper church. The body of St. Mark was originally placed here, but is now within the high altar of the upper church. Below the nave is an older crypt, the existence of which has only recently been discovered; it is not accessible, having been filled in with earth and rubbish at a very early period.

Choir and rood-screen.

The choir, which is raised about 4 feet above the nave, is separated from it by a marble rood-screen, formed of ancient columns, bearing a straight architrave surmounted by fourteen statues, viz., St. Mark, the Blessed Virgin Mary, and the twelve apostles. It extends across the aisles, forming a north apsidal chapel of St. Peter and a southern one to St. Clement. The rood-screen is signed as the work of the Venetians Jacobello and Pietro Paolo, sons of Antonio delle Masegne, 1394–97. The rood itself is of silver, dated 1394 and signed "Jacobus Magistri Marci Benato de Venetiis." The workmanship both of the silver crucifix and of the fourteen statues is of no great excellence. In front of the screen stand two very large ambones or pulpits, one of porphyry and the other of verde antico. In the northern ambo is a lofty patriarch's throne under a metal domed canopy, curiously like a pulpit in a Moslem mosque. There are fine marble baldacchini, supported on columns of precious marbles, over the high altar, two in the transepts and one on the north side of the nave. No less than five hundred columns of porphyry and costly marbles are used to decorate the church, especially on the west front. Some of those inside the atrium have no constructional use, but are only set against the wall for the sake of their beauty and value.

Columns and capitals.

A whole volume might be written on the sculptured capitals, panels, screens, and other features of the church. A great part of these are the spoils of other churches, especially from the East; much of the sculpture, as, *e.g.*, the parapets along the triforium gallery, dates from the 6th century or even earlier.[3] In the richly carved capitals every style from the 4th to the 12th century is represented, many of them being marvels of delicacy combined with extreme spirit of execution. Some of the larger caps are partially covered with a rich basket-work pattern completely under-cut with great technical skill; others have vine or acanthus foliage treated with vigorous realism; and a large number have the revived Byzantine treatment of the classic Corinthian or Ionic capitals, with variations showing the richest power of invention and originality. In addition to the elaborate sculpture, some of the capitals are decorated with inlaid patterns; and many of the mouldings, such as the capping of the triforium screen, are also ornamented in the same way. This use of inlay is almost peculiar to St. Mark's, as is also the method of enriching sculptured reliefs with backgrounds of brilliant gold and colored glass mosaics, producing an effect of extraordinary magnificence.[1]

---

[1] The exterior of the church of St. Demetrius at Thessalonica is covered with simple brick arcading, very like that which still exists in many places behind the marble lining of St. Mark's.

[2] The first edition of the *Stones of Venice*, together with an unfinished series of folio plates, most of them exquisitely drawn by Mr. Ruskin himself, was published in 1852; a carefully executed reprint of both was issued in 1886. This is one of the noblest monographs on any architectural subject that has ever been written.

[3] The church of St. Demetrius at Thessalonica contains many sculptured panels and other decorations exactly similar in style to those of St. Mark's; and other churches in Thessalonica and Trebizond have mosaic paving and glass wall-mosaics closely resembling those in St. Mark's. Even the plan of the Venetian basilica is Oriental in origin.

Exterior.

The exterior is no less magnificent than the inside, the whole façades being covered with sculpture, mosaic, or slabs of rich marble. The west façade especially is a marvel of lavish expenditure both of labor and of costly material. The design consists of two main stages, the lower one being formed by the atrium, a 12th-century addition, in front of the older façade. Each stage is divided into five great arches, decorated with richly sculptured archivolts and with tympana filled in with mosaic pictures. Only one of the original mosaics now exists on this front; all the rest have been destroyed and replaced by others of very inferior style in the 17th and 18th centuries. The one original mosaic is over the northernmost of the four doorways into the western atrium; its date is about or soon after 1220. It is of great decorative beauty, and its subject—the translation into the church of the body of St. Mark—is of great interest from its careful representation of the west façade of the church as it was at the beginning of the 13th century. It shows the original form of the upper part of the façade before the addition in the 14th century of the large ogee gables with elaborate crockets, alternating with statues, and intermediate pinnacled canopies placed between the five great arches of the upper story. It also shows the marble screen-work which once filled the great central west window, the whole of which is now missing, only the columns which supported it being left.[2] Similar filling-in still exists in some of the large side windows. The lower or atrium story is enriched with a wonderful collection of columns of precious marbles and porphyries arranged in two tiers. The sculptured archivolts, with foliage mixed with figures or subjects in relief, are of great beauty and variety. They are all carved in fine white Athenian marble, and were once gilt, as appears to have been the case with nearly all the sculptured ornaments of St. Mark's. This extensive use of gold is clearly shown in Gentile Bellini's picture. The top of the atrium forms a wide upper gallery communicating with the interior at the triforium level. In the centre of this gallery stand the four colossal bronze horses, from some Græco-Roman triumphal quadriga, which were brought to Venice after the conquest of Constantinople by Enrico Dandolo in 1204.[3]

Roofs.

The roofs, including the five great external domes over the nave, choir, transepts, and crossing, are all covered with thick sheets of lead. The internal domes, like the rest of the vaults, are of brick, the external domes being of wood. The drums on which the outer domes rest are bound round with strong iron bands, which were added by Jac. Sansovino in the 16th century. The round-headed windows in the drums were once filled in with pierced screen-work of marble, some examples of which still exist in the western atrium,—an interesting relic of the method of filling windows employed at a time when glass was but little used.

Mosaics.

The mosaics in the interior are among the finest and, from their variety of date, the most interesting series in the world; those dating from the 12th and 13th centuries are of special beauty. The earliest appear to be those on the five great domes, probably executed before 1150. On the nave dome the subject is the Descent of the Holy Spirit: tongues of fire radiate upon colossal figures of the apostles, and below them, on the drum of the dome, is a second series of figures representing the various nations of the world who were converted through the inspired teaching of the apostles. On the dome over the crossing is the Ascension of Christ, with bands of large figures of the Apostles, and below them the Virtues. On the choir dome are a half figure of Christ and a series of the Prophets. In the main apse is Christ in Majesty. The transept domes have series of Saints and Doctors of the Church. All have explanatory inscriptions. The whole of the rest of the vaults and the upper portion of the walls are covered with mosaic pictures, of which a mere catalogue would occupy many pages. In the atrium the subjects are taken from the Old Testament; these date from *c.* 1200–1300. In the baptistery[4] are the life of St. John the Baptist and scenes from the life of Christ; on the first dome (westwards) is Christ in Majesty over a series of baptismal scenes and the Greek Doctors; on the second dome, Christ surrounded by Angels. On the barrel vault of the chapel of St. Isadore is a very beautiful series of mosaics, with scenes from the saint's life and other subjects, executed in 1355, soon after the completion of the chapel. In the sacristy is a fine series of 15th-century mosaics, and in other parts of the church there are mosaics of still later date, some of them from cartoons by Tintoretto and other Venetian painters of the decadence. These later mosaics are not designed with any real sense of the special necessities of mosaic work, and are all very inferior in decorative effect to the simple Byzantine style from the 12th to the 14th century.

Pavement.

Most of the existing mosaics of the earlier periods have suffered very seriously from "restoration," a process which is still going on, with most fatal results to the interest and real value of the mosaics. The exterior marble facing and much of the sculpture have within recent years been completely renewed in the most tasteless way,—the fine slabs of rich Oriental marbles having been largely replaced by cheap grayish Carrara marble of the worst quality, quite devoid of the fine colors and rich veinings of the original slabs. The same fate now threatens the magnificent mosaic pavement of St. Marks, the surface of which has sunk into a succession of wavy hollows, owing to the settlement of the vaulting of the crypt below on which the nave paving rests.[5] The original part of the mosaic floor probably dates from about the middle of the 12th century. The nave pavement of the cathedral at Murano, which is exactly similar in style, materials and workmanship, has an inscription dated 1140. The pavement of St. Mark's consists partly of opus Alexandrinum of red and green porphyry mixed with some marble, and partly of tesselated work, made both of glass and of marble tesseræ. The two methods are obviously of the same date, as in some cases both processes are used in the same design. The opus Alexandrinum is very similar in style to that of some of the basilicas of Thessalonica, and also those in Rome, most of which are of about the same date, the 12th century. The designs executed in mosaic tesseræ are of several different styles, some being taken from the mosaics of Roman classical times, while others, with large panels of peacocks on each side of a vase, eagles or lions devouring their prey, and the like, are copied from Byzantine reliefs of much earlier date than the 12th century.[6] The originals of many of these are to be seen in the sculptured roundels which stud the façades of Byzantine palaces in Venice. A great part of the pavement of St. Mark's has been repaired and renewed at various times, from the 14th century down to the present time; consequently a great variety of styles and materials occurs mixed with the original parts. The pavement in the north aisle was renewed in the most clumsy and spiritless fashion about twenty years ago, and it is much to be feared that a similar fate awaits the rest of these priceless mosaics.

Retable or Pala d'Oro.

One of the great glories of St. Mark's is the most magnificent gold retable in the world, most sumptuously decorated with jewels and enamels, usually known as the Pala d'Oro. It was originally (according to the Venetian chronicles) ordered in Constantinople by Doge Pietro Orseolo I. in 976; and an inscription in enamelled letters added in 1345 records that it was brought to Venice and partly renewed by Doge Ordelafo Falieri in 1105; in 1209 it was again repaired and enlarged by Doge Pietro Ziani; and finally in 1345 Andrea Dandolo reset the enamels in new framework, and added some minute gold canopies and other decoration of Gothic style. In the 19th century it was thoroughly repaired and the stolen gems replaced by new ones, easily distinguishable from the original jewels by being cut in facets, not "en cabochon" after the old fashion. This marvellous retable is made up of an immense number of microscopically minute gold cloisonné enamel pictures, of the utmost splendor in color and detail. The enamels are partly translucent, allowing the brilliant gold backing to shine through the colored enamel. The subjects are Christ in Majesty, figures of Archangels and Angels, and a very large number of single figures of Prophets and Saints, as well as many scenes from the life of Christ and of St. Mark. No description can do justice to the splendor of effect produced by this gleaming mass of gold, jewels, and enamels; the delicacy of workmanship of the latter is only equalled by two Textus covers, also in gold cloisonné, now preserved in the treasury of St. Mark, which also possesses a magnificent collection of church plate of all sorts, such as large chalices and patens in crystal and agate, reliquaries, candlesticks, altar frontals, and other kinds of church furniture, all of the most precious materials and workmanship.[1] Two silver frontals of the 14th century, now used for the high altar of St. Mark, originally belonged to the cathedral of Venice, S. Pietro di Castello.

---

[1] The most notable examples are over the doorways of the western atrium.

[2] This tracery, or rather screen-work, was removed before 1496, when Gentile Bellini painted his picture of the Piazza and West Front of St. Mark's. This very interesting picture shows the lost mosaics, the subjects of which appear to have been the same as those now existing.

[3] These bronze horses were carried off to Paris, with many other art treasures, by Napoleon in 1797; they were restored to their place in 1815 by Francis of Austria, as is recorded in a large inscription on the arch below them.

[4] A complete list of the subjects of the mosaics in the baptistery is given by Mr. Ruskin in his *St. Mark's Rest*, 1884, p. 129 *sq.*

[5] There is no ground whatever for the notion that the wavy surface of the pavement was produced intentionally. Its lines of depression simply follow the "cells" in the crypt vaulting, the loose filling-in of which allows more settlement than the rigid crowns of the vaults.

[6] It is interesting to note that a 6th or 7th century marble relief with the vase and peacocks, which forms part of the external facing of the treasury of St. Mark, has been copied exactly in one of the mosaics of the south aisle.

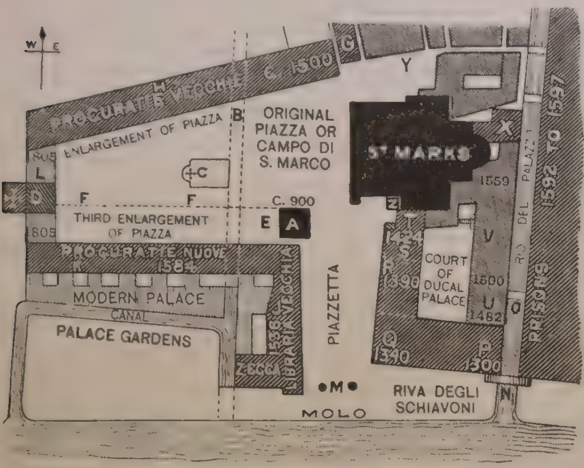

FIG. 3.—Square of St. Mark and surrounding buildings. The original *campo* was bounded on the west by the canal B, with the 6th-century church of S. Geminiano, C, on its west bank. The first enlargement of the square was effected by Doge Sebastiano Ziani in 1176, when he filled up the canal and rebuilt the church on a new site at D, thus nearly doubling the size of the square. Lastly, the square was extended southwards in the 16th century, when the new palace of the procurators, K, was built by Scamozzi. Gentile Bellini's picture shows a line of houses along FF, reaching up to the great campanile, A. Napoleon I. in 1805–10 pulled down the church of S. Geminiano and built a new block at the west end of the square, L. The dates of the various parts of the existing ducal palace are indicated on the plan; the rebuilding was carried on in the following order, P, Q, R, S, T, U, V. At Z is the treasury of St. Mark, which was originally one of the towers belonging to the old ducal palace; E, site of old houses; G, clock-tower; H, old palace of procurators; J, old library; M, two columns; N, Ponte della Paglia; O, Bridge of Sighs; W, Giants' Staircase; X, sacristy of St. Mark; Y, Piazzetta.

Ducal palace.

Early history.

The Ducal Palace.—The original doge's palace, probably a small strongly fortified castle, was built early in the 9th century, soon after the transference of the seat of government from the island of Malamocco to that of Rialto. In the early troublous period of Venetian history the ducal palace was frequently destroyed and rebuilt. It was burned in 976 and again in 1106; by 1116 it had been rebuilt. At the end of the 12th century Sebastiano Ziani (1173–79) restored and enlarged it. Of his work the only fragments now in existence are some richly sculptured bands in relief, built in at intervals along the 14th-century Rio façade, by the southeast angle of the palace (see P on Fig. 3). The present magnificent palace was a slow growth extending over nearly three centuries, the older building of Ziani being gradually pulled down as room was required for the new work.

Present palace.

The existing palace was begun in 1300–1 by Doge Pietro Gradenigo, who built the façade (P on Fig. 3) along the Rio, in which are inserted the 12th-century friezes of Ziani. About 1309 the arcaded façade along the sea front was begun at the southeast angle by the Ponte della Paglia (N on Fig. 3), and the design which was then adopted was accurately followed along the whole external façade, the building of which occupied about a century and a half. Towards the end of the 14th century the façade had been carried along the Piazzetta side as far as the tenth capital (counting from the southwest angle), which is carved with baskets of different kinds of fruit (R. on Fig. 3). At this point the work seems to have remained stationary for some years, and a considerable portion of Ziani's palace was still in existence; this was called the old palace to distinguish it from the 14th-century new palace. The Venetian council had decreed that a fine of 1000 gold ducats [gold $2,268] should be imposed on any of its members who proposed that the remaining part of the old palace should be rebuilt; in spite of this, in 1422, Doge Tomaso Mocenigo did propose and carried a resolution that the new palace should be extended over the site of Ziani's building. The doge paid the fine, and it was spent as a contribution towards the rebuilding, which was begun in 1424; in a few years the remainder of the external façade was completed up to the northwest angle, by the church of St. Mark (S. on Fig. 3). The magnificent gateway which unites the palace to the church, called the Porta della Carta[2] (T on Fig. 3), was added in 1439–42; it was the work of the sculptor Bartolomeo Bon and his son. Soon after the great balconied windows, which break the regularity of both fronts of the palace, were inserted in the upper story. The internal block in the great court joining the Porta della Carta to the Rio front was built by Doge Cristoforo Moro about 1462. In 1479 a fire consumed part of the 14th-century buildings along the Rio, and this part was then rebuilt mostly between 1480 and 1550. On the southern part of this block are the arms of Doge Agostino Barbarigo, 1482 (U on Fig. 3).

Façades.

The two main façades, those towards the sea and the Piazzetta, consist of a repetition of the same design, that which was begun in the early years of the 14th century. The name of the architect who began the work and thus fixed the design of the whole is not certainly known, but it must have been a man of an earlier generation than that of Filippo Calendario, who is often stated to have been the chief architect of the older portion. Calendario was an accomplice in the conspiracy of Marino Faliero and was executed together with the doge in 1355. It appears probable that a Venetian architect and sculptor named Pietro Baseggio was the chief master-builder in the first half of the 14th century.[3] The design of these façades is very striking, and unlike that of any other building in the world. It consists of two stories with open colonnades, forming a long loggia on the ground and first floors, with seventeen arches on the sea front (see Fig. 4) and eighteen on the other façade. Above this is a lofty third story, pierced with a few large windows, with pointed arches once filled with tracery, which is now lost. The columns of the middle story support heavy tracery of the characteristic Venetian form, which was copied with more or less modification in a very large number of private palaces built in Venice during the 14th and 15th centuries. The ground story has boldly moulded pointed arches, the spandrels of which were intended to be decorated with geometrical patterns in thin pieces of marble inlay. Only two of these were, however, completed. The main walls are wholly of brick; but none was left visible. The whole surface of the upper story is faced with small blocks of fine Istrian and red Verona marbles, arranged so as to make a large diaper pattern,

FIG. 4.—Section through sea front of ducal palace (see P, Q in Fig. 3). A. lower loggia towards sea. B. Upper loggia towards sea. C, D. Loggia towards inner court. E. Private apartments of doge. F. Offices. G. Modern level of pavement which hides the old stylobate of three steps (see Fig. 1).

---

[1] At the end of the 18th century the rich treasures of St. Mark's were sacked by the French, and much was then dispersed and lost, including many antique engraved gems and cameos from the Pala d'Oro.

[2] So named because public decrees and other papers were affixed to it.

[3] The edict for further rebuilding in 1422 names Baseggio as being the original designer of the 14th-century portion of the palace.

with, in the centre of each lozenge, a cross made of verde antico and other costly marbles. The colonnades, string-courses, and other decorative features are built in solid Istrian stone. Very beautiful sculpture, executed with an ivory-like minuteness of finish, is used to decorate the whole building with wonderful profusion. At each of the three free angles is a large group immediately over the lower column. At the southeast angle is the Drunkenness of Noah, at the southwest the Fall of Man, and at the northwest the Judgment of Solomon. Over each at a much higher level is a colossal figure of an archangel,—Raphael, Michael, and Gabriel. The sculpture of all the capitals, especially of those on the thirty-six lower columns, is very beautiful and elaborate, a great variety of subjects being introduced among the decorative foliage, such as the virtues, vices, months of the year, age of man, occupations, sciences, animals, nations of the world, and the like.[1] On the whole the sculpture of the 14th-century part is finer than that of the later part near St. Mark's. In many cases the 15th-century sculptors have simply copied the older capitals. A strong Florentine influence is apparent in all this sculpture, a great part of which was probably the work of Florentines.[2] Unhappily within recent years about half the old capitals have been removed and replaced by copies, which in some cases are not even accurate reproductions of the originals. A very wholesale and needless "restoration" is still in progress, not only of the sculpture, but also of the columns, arches, and traceries, which in many cases have been wholly renewed without any excuse whatever.

Internal court.

The great internal court is surrounded with arcading of very similar style; even in the 16th-century portion the same main outline has been followed though the detail is different. From the interior of the court access is given to the upper loggia by a very beautiful staircase of early Renaissance style, built in the middle of the 15th century by the Venetian architect Antonio Ricci. Two colossal statues of Neptune and Mars at the top of these stairs were executed by Fran. Sansovino in 1554—hence the name "giants' staircase"; they are very clumsy and badly designed. Owing to a fire which gutted a great part of the palace in 1574, the internal appearance of the rooms was completely changed, and the fine series of early Paduan and Venetian paintings which decorated the walls of the chief rooms was lost.[3] At present the magnificent council chambers for the different legislative bodies of the Venetian republic and the state apartments of the doges are richly decorated with gilt carving and panelling in the style of the Later Renaissance. On the walls of the chief council chambers are a magnificent series of oil paintings by Tintoretto and other less able Venetians,—among them Tintoretto's masterpiece—Bacchus and Ariadne—and his enormous picture of Paradise, the largest oil painting in the world. All have suffered much from restoration. Some of the scenes of important Venetian naval victories are of great historical interest, though of little merit as works of art.

State prisons.

In the 16th century the state prisons, which till then were on the ground floor of the ducal palace, were removed to a new building on the opposite side of the narrow canal on the east of the Rio del Palazzo (see Fig. 3). A bridge, usually known as the Bridge of Sighs, was built to connect the two buildings. This bridge and the new prisons[4] were designed by a Venetian, who also built the Rialto bridge in 1588–91, and hence was nicknamed Antonio da Ponte.

Owing to the raising of the level of the Piazzetta and the Riva degli Schiavoni, the ducal palace has lost its stylobate, consisting of three steps, the level of the pavement outside being now the same as that of the lower loggia of the palace; and thus a serious injury has been done to the architectural beauty of the façades (see Figs. 1 and 4). As the columns of the lower story have no bases, a stylobate is specially needed.

Piazzetta columns.

By the side of the sea in the Piazzetta, on to which the west façade of the ducal palace faces, stand two ancient columns of Egyptian granite, one red and the other gray (see M, Fig. 3). These great monoliths were brought as trophies to Venice by Doge Domenico Michieli in 1126, after his victories in Syria. In 1180 they were set up with their present fine capitals and bases by a Lombard engineer, Niccolo de' Barattieri. The gray column is surmounted by a fine bronze lion[5] of Byzantine style, cast in Venice for Doge Ziani about 1178; and in 1329 a marble statue of St. Theodore, standing upon a crocodile, was placed on the other column.[6]

Campanile.

The great campanile (see A, Fig. 3) of St. Mark in the square at the west of the church was founded about 900 by Doge Pietro Tribuno and finished in 1131 or soon after. It is a very massive square tower of brick, 325 feet high by 42 square, on a stone base, simply decorated with slight pilasters. The ascent to the top is made by a series of inclined planes instead of stairs. The upper part, an open lantern with a pyramidal roof, was added in the 16th century; on the apex is a fine colossal statue of an angel, formed of plates of gilt bronze on a wooden core,—a work of the end of the 15th century.

Cathedral church.

Other Churches.—The ancient cathedral church of S. Pietro di Castello was wholly rebuilt during the latter part of the 16th century, probably from designs by Palladio. It is a well-proportioned but uninteresting structure of the usual Pseudo-Classical Palladian style; it is now seldom used.

Churches of SS. Giovanni e Paolo and the Frari.

After St. Mark's the two finest churches in Venice are those of the Dominican and Franciscan friars, SS. Giovanni e Paolo and S. Maria Gloriosa de' Frari. Both are built on the same plan as that of other important friars' churches, such as S. Maria Novella and S. Croce in Florence, with a large nave, aisles, transepts, and two or more chapels opening from the east of each transept. In the Venetian examples the choir and all the transept chapels have apsidal terminations. Both churches are built of brick, with rich marble traceried windows, and simple vaulting throughout. The details of the interior are plain, but the scale is large and the general design very noble and effective, showing a strong infusion of northern Gothic influence, which is one of the characteristics of the friars' churches throughout Italy. The Dominican church of SS. Giovanni e Paolo was used as the chief burial place of the doges and other chief members of the Venetian republic;[7] it was built about the middle of the 13th century.[8] There is no foundation for Vasari's statement that Niccola Pisano was the architect of this or of any other building in Venice, although the influence of the Pisano school of sculpture was certainly very strong during the 14th century. The magnificent collection of tombs in this church, of all dates from the 13th century downwards, is one of the finest in the world. Some of the recumbent effigies of the 14th century, and the reliefs and statuettes on the sarcophagi, are works of very great beauty, distinctly Florentine in character. The later monuments of the 16th and 17th centuries are in many cases very large, costly, and pretentious, of the worst possible taste, in striking contrast to the quiet simplicity of the 14th-century tombs. A remarkable feature in the Franciscan church is its fine marble rood-screen of the 14th century, one of the very few which still exist in Italy; it is surmounted by two ambones or pulpits. The choir stalls, which extend rather more than one bay westwards of the crossing, are richly decorated with reliefs and tarsia work, executed in the later years of the 15th century. This church is the largest in Venice, even exceeding St. Mark's in size; it also contains a number of fine tombs, some of them with large equestrian statues of Venetian generals. The tomb of Doge Francesco Dandolo in this church, now mutilated and removed from its place, is a very noble example of 14th-century sculpture. The sacristy, on the south of the south transept, still possesses over its altar one of Giovanni Bellini's finest pictures, signed and dated 1485, representing the Madonna Enthroned between Standing Figures of Saints, a picture of most extraordinary beauty and perfect preservation, in its original richly carved retable-frame.[9] This church, though very similar in style, was built about half a century later than that of the Dominicans, and was not completed till after 1300.

---

[1] An excellent account of these sculptured capitals is given by Mr. Ruskin in his *Stones of Venice*, vol. ii. A treatise on the same subject was written by Didron and Burges, *L'Iconographie du Palais Ducale*, Paris, 1857, but the authors failed to recognize the true dates of the different parts of the palace.

[2] According to Zanotti, the capital at the northwest angle was signed "Duo Soci Florentino"; but this inscription is not now visible.

[3] Considerable remains of these paintings by Altichiero and other 15th-century masters still exist, though completely hidden by the later pictures on canvas.

[4] Many distinguished prisoners have suffered from violent heat in the *piombi* or roof cells, and from damp and cold in the *pozzi* or cellars, of these prisons.

[5] This lion, carried off to Paris, together with the four bronze horses and other Venetian spoils, by Napoleon I., was sent back in a very fragmentary condition; the lion's tail, the wings, and the book under its paws were added after its return to Venice in 1816. Originally the wings were much larger, and there was no book.

[6] See Ruskin, *St. Mark's Rest*, chap. ii.

[7] Andrea Dandolo, whose tomb is in the baptistery, date 1355, was the last doge buried in St. Mark's, which up to that time had been the usual ducal burying-place.

[8] It was founded about 1234, but not completed till some years later.

[9] Mr. Ruskin, *Shrine of the Slaves*, p. 38, calls this one of the two finest pictures in the world, the second being another Madonna by Gian. Bellini in the church of S. Zaccaria in Venice.

Church of S. Stefano, etc.

The influence of the chief orders of friars in the style of ecclesiastical architecture is strongly shown in many other churches, such as that of S. Stefano, especially in the frequent use of the apse as a termination both for choirs and side chapels. This church, built about 1360 by a monastery of Austin friars, has a rich west front, decorated with very delicate terra-cotta ornaments. The eastern apse extends over a small canal and is supported on a wide bridge-like arch. Of the same type are the church of S. Gregorio and that of S. Maria della Carità, both now desecrated. S. Gregorio has a very beautiful cloister, dated 1342, the columns of which support, not a series of arches, but flat wooden lintels. On the capital of each column rests a moulded wooden corbel to diminish the bearing of the lintel; this is a very characteristic Venetian mode of construction, used, not only for cloisters, but also for ground floors of houses, upper loggias, and other places, especially during the 14th and 15th centuries.[1]

S. Giacomo dall' Orio.

One of the most interesting early churches is that of S. Giacomo dall' Orio, built in the early part of the 13th century, with a complicated many-columned plan, the aisles being carried along the transepts as well as the nave. The roof is a very good example of the wooden coved type, of which the finest are at VERONA (*q.v.*). One of the columns in the south transept is a monolith of the precious verde antico, of wonderful size and beauty, probably brought from some Byzantine church.

S. Maria dei Miracoli.

Venice contains some very beautiful ecclesiastical architecture of the Early Renaissance, about 1450 to 1500, with very delicate and refined detail, such as was designed by Fra Giocondo of Verona and various members of the Venetian Lombardo family. The most perfect example of this style is the little church of S. Maria dei Miracoli, so called because it was built to contain a miraculous picture of the Madonna. Very rich and varied marbles were used in its construction, and it is lavishly decorated with sculpture of wonderful refinement and beauty of detail; it was built in 1481–89 from the designs of Pietro Lombardo. The court of the guild of St. John the Evangelist is another fine example of the same style.

Later Renaissance churches.

In the 16th century and even later some very stately churches of the Later Renaissance style were built in Venice by Jacopo Sansovino, Andrea Palladio, and their school. One of Sansovino's[2] best works, the church of S. Geminiano, was destroyed at the beginning of the 19th century in order to complete the west side of the square of St. Mark (see Fig. 3). The large church of S. Giorgio Maggiore, on an island opposite the ducal palace, was built by Palladio, and is a good example of the faults and merits of his style. S. Maria della Salute, built by Baldassare Longhena in 1632, as a thank-offering of the Venetian senate for the cessation of the great plague in 1630, is one of the most conspicuous churches in Venice, owing to its magnificent site near the mouth of the Grand Canal. Though dull and heavy in detail, it has a well-designed dome, and the general mass of the building is very skilfully arranged. Most of the 17th and 18th century churches in Venice are in the worst possible taste, and extravagantly pretentious in style. A large number still possess fine campanili,—lofty square brick towers, in general form not unlike the 12th-century campanili of Rome. These in Venice range from the 11th to the 16th century, those of the 14th century being specially beautiful.

Palaces.

Palaces.—In the beauty and interest of its domestic architecture Venice ranks before any other city in the world. Fine examples of all dates from the 12th century downwards still exist, and many even of the earlier palaces are still externally in a very perfect state of preservation.

12th-century Byzantine palaces.

The most notable specimens of 12th-century Byzantine palaces are those of Loredano (now municipal offices), Farsetti, and Da Mosto, all on the Grand Canal. The *fondaco* of the Turks (now the Correr Museum) was once the finest of this date, but it has been ruined first by neglect and then by wholesale restoration.[3] The general design of these Byzantine palaces appears to have been very similar in all cases; Fig. 5 shows a typical example. The canal façade usually had a tower at each end, with a row of arches in the centre opening into a long vestibule or porch, behind which was a large hall. Along the first floor a long range of window arches extended from end to end, forming a continuous arcade; in the *fondaco* of the Turks this upper range consisted of no less than twenty-six arches. Very beautiful sculpture was used to decorate all these arches, which were of stilted semicircular form, and also the capitals on which they rested. Mr. Ruskin has shown how these round arches developed into other forms, first a simple pointed ogee, and then a cusped ogee of several different varieties.

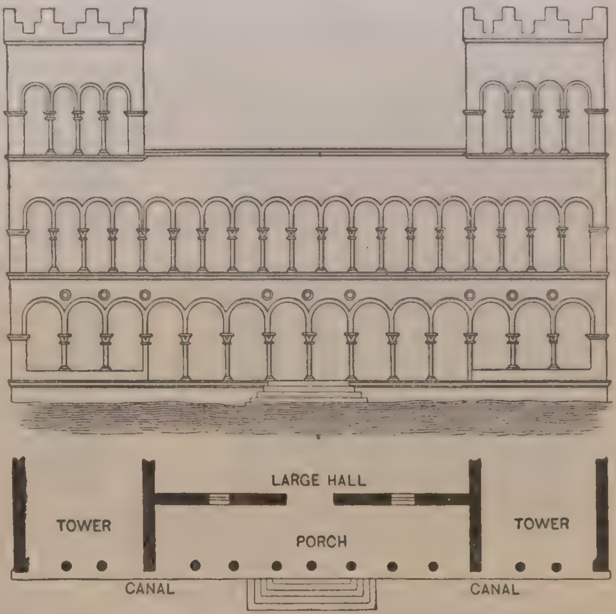

FIG. 5.—Typical façade and plan of a 12th-century Byzantine palace, with a tower at each end. No perfect example now exists, owing to the rebuilding of the upper stories with central part equal in height to the ends; but in many cases traces of this arrangement can be distinguished.[4]

Venetian Gothic palaces.

In the 13th century the introduction of window-tracery led gradually to the development of a special form of architecture, usually called Venetian Gothic, which was unrivalled for combined magnificence of material and design. The design of about the year 1300 adopted for the façade of the ducal palace had a very extensive and prolonged influence on the private palaces of Venice. A very large number of these, built in the 14th and first half of the 15th century, still exist and are among the most beautiful and well-preserved examples of mediæval architecture which can anywhere be seen. The climax of this magnificent style was towards the end of the 14th century, to which date belongs the wonderful Ca' d'Oro or "golden house," as it is usually called, from the profusion of gilding which once covered its sculptures and mouldings. No words can describe the magnificence of this palace on the Grand Canal, its whole façade faced with the most costly variegated Oriental marbles, once picked out with gold, vermilion, and ultramarine, the walls pierced with elaborate traceried windows and enriched with bands and panels of delicate carving,—in combined richness of form and wealth of color giving an effect of almost dazzling splendor.[5]

Ca' d'Oro.

Early Renaissance palaces.

Some of the 15th century palaces of Early Renaissance or, as Mr. Ruskin calls it, Giocondesque style are scarcely inferior in beauty to those of the Gothic period. Fra Giocondo, the Lombardi, and other architects of this era (1460–1510) still used with great skill and effect the rich Oriental marbles, which were wholly neglected by the architects of the Pseudo-Classic revival. On the Grand Canal the Corner-Spinelli, Trevisan, and Dario Palaces are especially beautiful examples of the style; the richest of all is, however, the small Guisetti Palace in the narrow Rio della Fava, faced with purple Phrygian pavonazzetto and other colored marbles, and lavishly decorated with delicately sculptured pilasters, friezes, and corbels of the most exquisite design and workmanship. This architectural gem is now quite neglected, and used as a mere warehouse.

---

[1] A fine loggia of this class exists in the ducal palace, opening on to the upper loggia of the Piazzetta façade.

[2] For others of his works in Venice, see SANSOVINO.

[3] A very beautiful fragment of an early palace in the Rio Foscari has been well illustrated by Mr. Ruskin in his plates to *Stones of Venice*, 1886.

[4] Mr. Ruskin has shown (in *Stones of Venice*, vol. ii.) that in these Byzantine palaces there are subtle variations in the width of the arches, forming a regular gradation of sizes, hardly perceptible without actual measurement.

[5] Signor Giacomo Boni has given, in *Proc. Inst. Brit. Arch.* for February, 1887, a very interesting account of the decorations of this palace, and of the addition of its elaborate cornice (now destroyed) in 1424 by Bart. Bon, who was paid 210 gold ducats for his work.

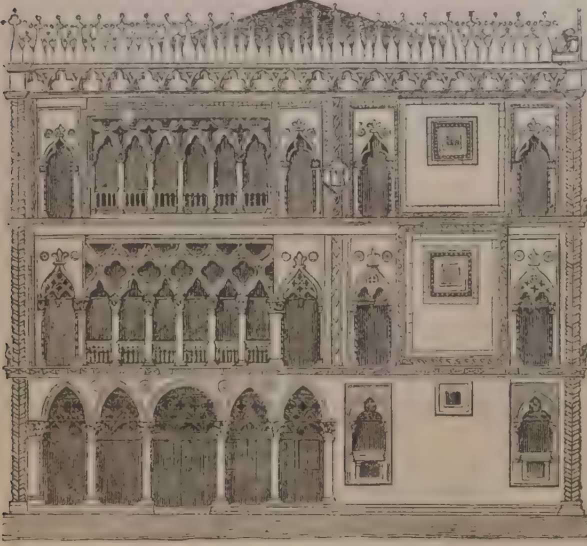

FIG. 6.—Ca' d'Oro, as originally built.

Among the 16th century palaces of later style are many of great size and magnificence, though designed in a somewhat dull and scholastic fashion. The influence of these Venetian buildings on the 19th century architecture of Europe generally has been very great.[1]

Later Renaissance.

In most of the Venetian palaces of the Later Renaissance, such as the magnificent Grimani Palace by Sammichele, and in the library of St. Mark by Sansovino, the main motive of the façade is taken from the arcading with entablature over engaged columns which was universally used for the theatres and amphitheatres of ancient Rome. In many cases the entire façade of the palace consisted of a series of columns, arches, and cornices, so that no plain wall surface was left at any part of the front, and the whole effect is too labored and restless, and far less pleasing than the rather earlier examples of the same style, such as the Vendramini Palace on the Grand Canal and the Camerlenghi near the Rialto bridge, finished in 1525, in which some Gothic feeling still survives. One of the noblest palaces of the Later Renaissance is that of Pesaro, on the Grand Canal, built by Longhena, one of the chief Venetian architects of the 17th century, who in this case has followed the style of Sansovino or other architects of the previous century, using the Colosseum arcade for the two upper stories. In general mass and in the proportions of the parts this palace is a work of great merit, far superior to the usually degraded style of the 17th century.

Guilds.

Other Public Buildings.—Much of the splendor of Venice in her days of greatest glory was due to the wealth and religious zeal of the various trade guilds or confraternities, called *scuole* by the Venetians. The members of each guild were united for both secular and religious purposes; their meeting places and chapels were often buildings of the greatest architectural magnificence, and were decorated with sculpture and painting by the chief artists of the time. The *scuola* of St. Mark, near the great Dominican church, has a magnificent façade designed in 1485 by Pietro Lombardo. A beautiful series of pictures by Vittore Carpaccio was painted for the Slavonian guild, and still exists in their chapel dedicated to St. George and St. Tryphonius. The *scuola* of St. Rocco possesses a wonderful collection of noble pictures by Tintoretto, and the other chief guilds, such as those of St. Ursula, Della Misericordia, Della Carità, and St. John the Evangelist, possessed beautiful and richly decorated buildings.

Arsenal.

One of the most important public buildings of Venice was the arsenal,[2] including large docks and yards for building ships (see p. 155 above). The entrance gateway is an elaborate work, built in 1460 by the Lombardi; and in front of it stand four ancient marble lions, brought as trophies from the Piræus in 1687.[3] The arsenal is still an important naval depot, and contains a museum of historically interesting objects.

Public buildings round St. Mark's Square.

A stately series of public buildings surrounds the Square of St. Mark's (see Fig. 3). The north side is occupied by the old palace of the procurators, designed by Bart. Bon towards the end of the 15th century. Near it to the east stands an elaborate clock-tower built by Pietro Lombardo in 1496. On the south of the square is the newer palace of the procurators, designed in 1584 by Scamozzi, now used as part of the royal palace. The west end is occupied by an extension of the public offices built by Napoleon I. in 1805–1810, partly over the site of the church of S. Geminiano. The adjoining Piazzetta is bounded on the east by the ducal palace and on the west by the magnificent library[4] of St. Mark, built by Jacopo Sansovino in 1536. The mint occupies part of the same block. The façade of the library is shown in Fig. 7.

In front of the west façade of St. Mark's are three large flagstaffs, originally used to display the gorgeous silk and gold banners of the subject kingdoms of the Morea, Cyprus, and Candia. Their elaborate bronze sockets were cast in 1505 by the Venetian sculptor, Alessandro Leopardi, who has inserted fine medallion portraits of the reigning doge Lorenzo Loredano.

Museums and galleries.

The academy of fine arts, now in the Della Carità guild-house, contains a very large and valuable collection of pictures of the Venetian school. With one exception, Carlo Crivelli, all the chief Venetians are well represented here, and in many cases far better than in any other collection in the world. Venetian art, in fact, can only be completely studied in Venice. The academy is very rich in elaborately carved retables of the early Venetian painters, works of great decorative splendor, though not equal in drawing or composition to the work of the 14th and early 15th century painters of Florence or Siena. The Vivarini family, the Bellini, with Carpaccio and others of the Bellini school,

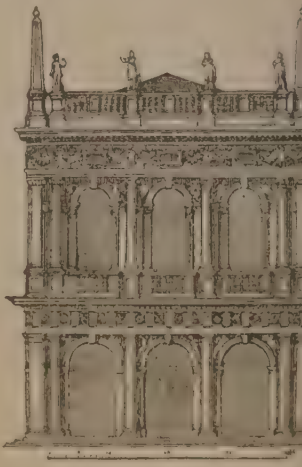

FIG. 7.—The library of St. Mark's, begun in 1536.

---

[1] In London the façades of many of the principal public buildings have been copied with but little alteration from Venetian originals, as *e.g.*, the Army and Navy Club in Pall Mall from Jac. Sansovino's Cornaro Palace (1532), with the omission of the middle story, and the Piccadilly School of Mines from the inner court of the doge's palace.

[2] Dante, *Infer.*, xxi. 7–15, describes the various operations in the arsenal at Venice.

[3] On the largest of these lions is cut a runic inscription recording a successful attack on the Piræus in the 11th century by a party of Norse warriors of the Varangian guard, under Harold Hardrada, who afterwards (in 1047) became king of Norway (see *Arch. Journ.*, xvi. pp. 188–192).

[4] This library contains about 65,000 volumes, with 5000 MSS., among which are some very valuable and artistically magnificent codices.

Cima da Conegliano, Titian, Tintoretto, and Paul Veronese are all represented by a large number of their finest works. The Correr Museum, now moved from the Correr palace to the *fondaco* of the Turks, is the property of the city. It contains some fine Venetian pictures, and an interesting collection of early majolica and other mediæval works of art. The Giovanelli Palace in the Rio S. Felice possesses a fine specimen of Giorgione, the rarest of Venetian masters: it is a noble woody landscape with two figures in the foreground. The portraits by Titian and Tintoretto in the same collection are very fine.

The churches of Venice are still marvellously rich in pictures by the chief Venetian painters of all dates. Almost every church contains some notable painting; and some of them, such as S. Sebastiano, S. Giovanni in Bragora, and S. Giorgio Maggiore, possess a very great number of important works. Many private palaces contain fine collections of pictures; but great numbers of these were sold to foreign purchasers during the 19th century.

Painting.

Painting.

For an account of Venetian painting the reader is referred to the separate articles on the various painters and to SCHOOLS OF PAINTING.

Sculpture.

Sculpture.

Till the 14th century Venice continued to adhere to the old Byzantine style of sculpture,[1] which, though often delicate in execution and decorative in effect, slowly lost spirit and vigor, and from continually copying older forms gradually degenerated into a dull and mechanical formalism. Early in that century the influence of Niccola Pisano and his school began to awaken a new artistic life among the archaistic sculptors of Venice; but the progress of this Renaissance was very slow, and in much of the Venetian sculpture the degenerate Byzantine formalism survived till nearly the close of the 14th century. Other works of the same period were executed with much of the grace and almost realistic beauty for which the contemporary Florentines were so famous, and thus one may see in Venice, and in Venice only, two reliefs of the same date of which one is several centuries earlier in style than the other.[2] This want of originality was probably partly caused by the immense quantity of older sculptured reliefs which was imported to adorn the walls of the churches. In the early part of the 14th century Florentine influence rapidly gained ground, and many sculptors from Florence came to work on the richly carved capitals of the ducal palace and other places, and especially produced a large number of very beautiful tombs with recumbent effigies. One very graceful type, the general motive of which was first used by Arnolfo del Cambio (see ORVIETO), was frequently repeated: at the head and foot of the effigy an angel is represented drawing a curtain so as to expose the figure of the dead man.[3] The sarcophagus, on which the effigy lies, has reliefs of the Virgin and the Angel of the Annunciation, with the Crucifixion or some other sacred subject between. In later times these subjects were usually replaced by allegorical figures of the virtues,[4] and the simple curtain drawn by angels gradually became a large tent-like canopy, of rather clumsy and tasteless form. In most churches the sculptured decoration, apart from that on the tombs, was concentrated on the west façade, the tympanum of the central doorway being often filled with a very fine relief, such as that from the church of the guild Della Misericordia, now in the South Kensington Museum.

In domestic architecture sculpture was but little used after the Byzantine period, the splendor of the façades depending mostly on their rich colored marbles, and on moulded tracery and string-courses. Nevertheless, even as late as the 15th century it was not uncommon to insert 11th or 12th century pieces of sculpture in new work; many examples of this practice are still to be seen. The sculpture of the Early Renaissance is very abundant and extremely delicate and refined, especially that of the Giocondo and Lombardi schools; S. Maria dei Miracoli contains some of the most beautiful examples.

Though not the work of a Venetian, Venice possesses what is perhaps the most magnificent equestrian statue in the world, the colossal bronze portrait of the Venetian commander-in-chief, Bartolomeo Colleoni (figured in vol. xxi, p. 595, Fig. 18),[5] which stands in the square at the west end of SS. Giovanni e Paolo. It was modelled by the Florentine VERROCCHIO (*q.v.*), and was cast after his death by Alessandro Leopardi, who also designed the pedestal; the whole was completed in 1495.

With the later development of the Renaissance, sculpture rapidly declined; in domestic architecture it was but little used, except for the deep frieze under the top cornice, and with the Palladian school it became still rarer, and very mechanical in style. In the 17th century it was again used in the most lavish way as architectural decoration, but was coarse in execution and violently awkward in outline. As Venice in her best days had produced some of the finest decorative sculpture in the world, so in her extreme decadence an almost unequalled depth of degradation was reached, and this continued till the fall of the republic. The Venetian sculptor Canova was, on the whole, superior to his immediate predecessors, and was one of the leaders of the revival of classic sculpture which flourished during the first half of the 19th century.

Minor Arts.

Metal-work.

During the early part of the mediæval period the Venetians had no great skill in metal-work. Some of the bronze doors in the west façade of St. Mark's are importations from Byzantium. That on the right, which has rude figures of saints inlaid in silver, was brought to Venice in 1204; another with a Latin inscription appears to be native work of about the year 1112; both are very rude in design and execution. The open bronze grills of the west atrium doorways, which are signed as the work of a Venetian goldsmith, Bertuccius, in 1300, show no increase of technical skill. Nor was the silver-work any better: the large silver rood in St. Mark's is a very coarse piece of work. The silver altar frontals from the old cathedral, now in St. Mark's, with sacred subjects and figures of saints repoussé in each panel, made in the 14th century, are no less rude in design and feeble in execution. As in the case of marble sculpture, Venice was chiefly dependent on foreign importations for its rich stores of treasures in the precious metals. In the latter part of the 15th century Venetian skill in bronze-work had greatly increased. Leopardi, who cast Verrocchio's statue of Colleoni, was a bronze-worker of great eminence; and in the following century the bronze doors and the front cover[6] in St. Mark's by Jacopo Sansovino are models of technical excellence, though showing some decadence of taste in their design. The great bronze lion on the west façade of St. Mark's, cast by Gaetano Ferrari in the first half of the 19th century, is a really fine work. A great deal of beautiful metal-work, especially in copper and bronze, such as large salvers, ewers, and the like, was made during the 15th and 16th centuries, partly by Moslem workmen and partly by native Venetians who adopted Oriental designs. A large colony of Moslem craftsmen seem to have settled in Venice, and had much influence on the designs used in many of the minor arts.

Textiles.

Moslem influence was especially strong in the case of woven stuffs, for which Venice became very celebrated in the 15th century. Its damasks and other silk stuffs with patterns of extraordinary beauty surpassed in variety and splendor those of the other chief centres of silk weaving, such as Florence and Genoa. Fig. 7 in the article TEXTILES (vol. xxiii. p. 227) gives a beautiful example of 15th-century Venetian silk designed under Oriental influence. In addition to the native stuffs, an immense quantity of costly Oriental carpets, wall-hangings, and other textiles was imported into Venice, partly for its own use, and partly for export throughout western Europe. Thus in wealth of gorgeous stuffs and embroideries Venice surpassed all other cities, and on occasions of festivals or pageants the balconies, the bridges, the boats, and even the façades of the houses were hung with rich Eastern carpets or patterned textiles in gold and colored silk. The glass manufactory of MURANO (*q.v.*), a small island about 1½ miles to the north of Venice, was a great source of revenue to the republic; the glass-workers enjoyed special privileges and great pains were taken to preserve the secrets of the craft. Glass drinking cups and ornamental vessels, some decorated with enamel painting, and "silvered" mirrors were produced in great quantities from the 14th century downwards, and exported to other European countries, where they were sold for high prices. Much beautiful glass-work is still

Glass-working.

---

[1] Some of the early doges are buried in sculptured sarcophagi of the 5th or 6th centuries brought from elsewhere.

[2] As, for example, the reliefs over the doorway of the cloister of the scuola Della Carità, both of the 14th century.

[3] The tomb of Andrea Dandolo in St. Mark's (c. 1350) is one of the earliest in which this motive is used.

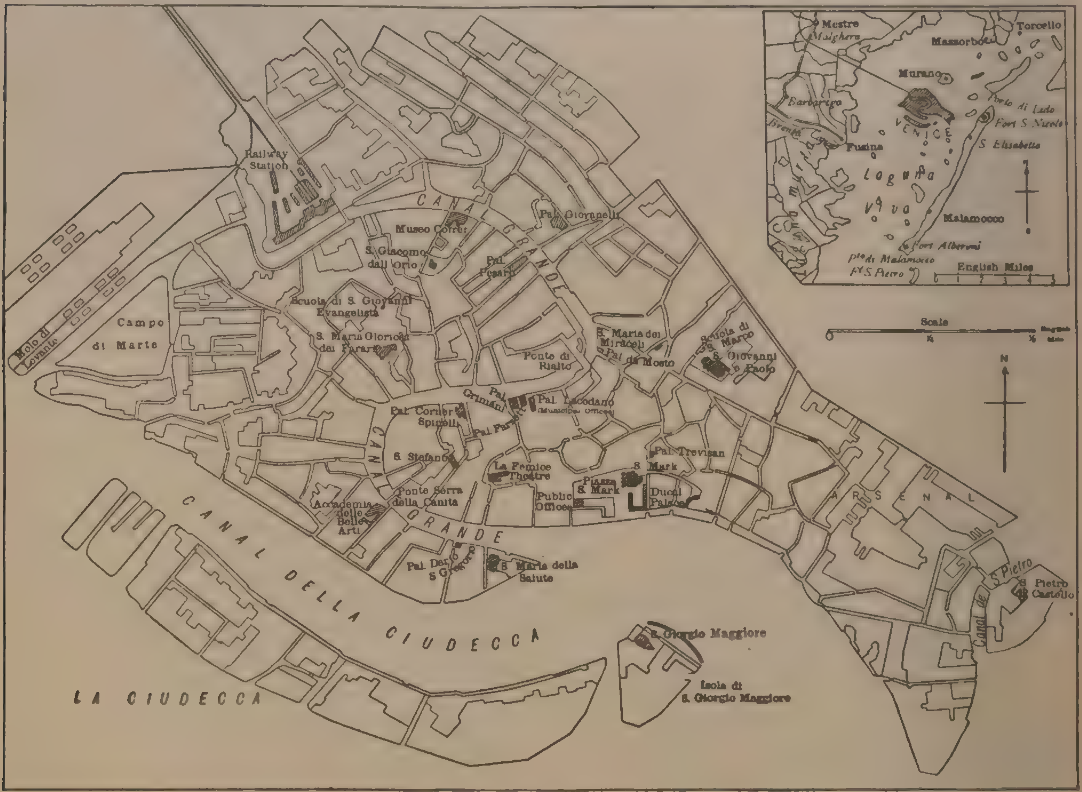
[4] The 14th-century tomb of the Florentine ambassador, Duccio degli Alberti, is the first in Venice which has representations of the virtues.

[5] See Vasari's *Life of Verrocchio.*

[6] This is usually attributed to Sansovino; but, according to Moschini, a document among the archives of St. Mark's records that it was made by Desiderio of Florence and Tiziano of Padua.

produced in Murano, but the workmen have lost all power of original design, and do little but copy the forms invented in the 15th or 16th century. Like many other arts in Venice, that of glass-making appears to have been imported from Moslem countries, and the influence of Oriental design can be traced in much of the Venetian glass. The art of making stained glass windows was not practiced by the Venetians; almost the only fine glass in Venice is that in a south transept window in the Dominican church, which, though designed by able Venetian painters, is obviously the work of foreigners.

The fine woodcut bird's-eye view of the city in 1497, engraved by Jacobo de' Barbari, is about to be published in facsimile with descriptive text by Giacomo Boni.



Map of the islands of Venice.

PART III.—MODERN CITY.

The modern city stands on 117 islands, separated by 150 canals (*rio*) and united by 380 bridges; all the main traffic passes along the canals. The usual range of tide-level is about 20 inches; but under exceptional circumstances there is a difference of nearly 6 feet between lowest and highest water. The name "gondola" given to the passenger boats does not occur earlier than the 14th century. As shown in Carpaccio's and Gentile Bellini's pictures (*c.* 1500), the gondola of that date was quite unlike the present boat with its heavy black cabin and absence of any coloring: the older form had an awning of rich stuffs or gold embroideries, supported on a light arched framework open at both ends.[1] The peculiar method of rowing with one oar at the stern is the same now as it was in the 15th century, and probably much earlier. Since 1880 "omnibus" steamers have been introduced on the Grand Canal, which has also been disfigured in the 19th century by the addition of two hideous iron bridges, over one of which passes the railway that connects Venice with the mainland. Before the Venetian republic was suppressed by Napoleon I. the population amounted to nearly 200,000; in 1830 it had sunk to about 100,000; but since then it has increased, and in 1881 amounted to 132,826 (commune 145,637). The city has grown rapidly in prosperity since its restoration to the kingdom of Italy, and it is now second only to Trieste among the seaports of the Adriatic. The climate is mild but somewhat rainy, owing to the water-surrounded site. The principal manufactures of the city remain what they were in the Middle Ages, namely, gold and silver work, glass, and velvet and silk, to which must now be added cotton, in all of which, as well as in grain, oils, wine and spirits, fruits, drugs, fish, and hides and leather an active trade is carried on. In 1886 the total value of the exports from Venice to foreign countries amounted to £7,239,479 [$35,183,867.94] and that of the imports to £8,788,012 [$42,709,738.32]. During the same year there entered 2595 vessels of 714,642 tons (Italian 1565 vessels of 222,217 tons) and cleared 2597 of 724,740 tons (Italian 1565 vessels of 227,021 tons). (J. H. M.)

---

[1] The use of black was made compulsory by a sumptuary edict of the great council in the 16th century.

VENLO, a frontier town of Holland, in the province of Limburg, on the right bank of the Meuse (here crossed by a bridge), is an important railway junction; Cologne lies 60 miles to the southeast and Maestricht 43 miles to the southwest. The population, which is somewhat closely packed, was 8494 in 1876 and 10,550 in 1887. None of the public buildings has any special interest attaching to it. The leading industries are distilling, brewing, tanning, spinning, needle-making, and tobacco manufacture. There is considerable trade by river with Rotterdam. Venlo was at one time a place of strength, but the fortifications were dismantled in 1868.

VENTILATION is the process of changing the air of rooms and other closed places so that a certain standard of purity may be preserved notwithstanding the vitiation which the air undergoes from the breath of inhabitants, the products of combustion of illuminating agents, and other causes. In estimating the amount of air to be supplied, account must be taken of the standard of purity which is aimed at and of the rate at which vitiation occurs.

Carbonic acid in air.

Of the various impurities that are found in the air of inhabited rooms carbonic acid forms the most ready index of the ventilation. The open air of London and other large inland towns contains about four parts by volume of this gas in 10,000 of air. In the country and in towns near the sea two or three and a half parts in 10,000 is a more usual proportion. Authorities on ventilation usually take four parts in 10,000 as the standard for pure air, and use the excess over that quantity in estimating the adequacy of the air supply. But they differ as to the proportion to which the carbonic acid may be allowed to rise in good ventilation. It is generally admitted that the air in which people dwell and sleep should not under any circumstances be allowed to contain more than ten parts in 10,000. This has been accepted as the permissible proportion by Carnelley, Haldane, and Anderson, after an extensive examination of the air of middle and lower class dwellings.[1] De Chaumont, judging by the rough and unsatisfactory test afforded by the sense of smell, concluded that the air of a room ceased to be good when it contained eight volumes of carbonic acid in 10,000 of air,[2] and recommends that six parts in 10,000 be taken as the maximum permissible in good ventilation. Parkes, in his *Manual of Hygiene*, quotes observations which point to an equally exacting standard as desirable.

Standard of purity.

Rate of consumption of air.

The rate at which an adult respires carbonic acid varies widely with his condition of repose, being least in sleep, greater in waking rest, and very much greater in violent exercise. As a basis on which to calculate the air necessary for proper ventilation we may take the production of carbonic acid by an adult as 0.6 cubic feet per hour.[3] Hence he will produce per hour, in 6000 cubic feet of air, a pollution amounting to one part of carbonic acid in 10,000 of air. If the excess of carbonic acid were to be kept down to this figure (1 in 10,000), it would be necessary to supply 6000 cubic feet of fresh air per hour; if the permissible excess be two parts in 10,000, half this supply of fresh air will suffice; and so on. We therefore have the following relation between (1) the quantity of air supplied per person per hour, (2) the excess of carbonic acid which results, and (3) the total quantity of carbonic acid present, on the assumption that the fresh air that is admitted contains four parts by volume in 10,000:

Air supplied per Adult per Hour.	Carbonic Acid (Parts by Volume in 10,000).	
	Excess due to Respiration.	Total Quantity.
Cubic Feet.		
1000	6	10
1200	5	9
1500	4	8
2000	3	7
3000	2	6

Thus, to preserve the lowest standard of purity tolerated by sanitarians, ventilation must go on at the rate per person of 1000 cubic feet per hour, and 3000 cubic feet per hour are required to preserve the higher standard upon which some authorities insist. Parkes advises a supply of 2000 cubic feet of air per hour for persons in health and 3000 or 4000 cubic feet for sick persons. The English Barracks Improvement Commissioners[4] require that the supply be not less than 1200 cubic feet per man per hour. Pettenkofer recommends 2100 cubic feet, and Morin[5] considers that the following allowances are not too high:

Hospitals (ordinary)	2000 to 2400	cu. ft.	per hour.
" (epidemic)	5000	"	"
Workshops (ordinary)	2000	"	"
" (unhealthy trades)	3500	"	"
Prisons	1700	"	"
Theatres	1400 to 1700	"	"
Meeting halls	1000 to 2000	"	"
Schools (per child)	400 to 500	"	"
" (per adult)	800 to 1000	"	"

Vitiation by burning gas.

Gas lights add to the vitiation of the air of rooms at a rate which may be roughly estimated by treating one cubic foot of gas burnt per hour as nearly equivalent to one adult person, so far as the production of carbonic acid is concerned. Thus an ordinary burner, giving a light of about twenty candles and burning four cubic feet of gas per hour, uses the air of three or four men.

Cubic capacity of rooms.

The purity of the air of a room depends, of course, to some extent, on the proportion of its cubic capacity to the number of inmates. The influence of capacity is, however, often overrated. Even when the allowance of space is very liberal, if no fresh air be supplied, the atmosphere of a room quickly falls below the standard of purity specified above; on the other hand, the space per inmate may be almost indefinitely reduced if sufficient means are provided for systematic ventilation. Large rooms are good, chiefly because of their action as reservoirs of air in those cases (too common in practice) where no sufficient provision is made for continuous ventilation, and where the air is changed mainly by intermittent ventilation, such as occurs when doors or windows are opened. It must be borne in mind, too, that no room is hermetically sealed. In the absence of proper inlets and outlets casual ventilation goes on through every chink and cranny, and even by diffusion through the plaster of the walls. The ventilation given in this way is generally most inadequate; but a large room has at least the advantage over a small one that it offers more chances for the casual entrance of fresh air, as well as a larger wall-surface through which diffusion may occur. It has also the advantage that a greater volume of air may more easily be passed through it than through a small room in a given time, without causing disagreeable draughts. A general idea of the cubic capacity per inmate, allowed by law or by custom in certain cases, is given in the table below:

---

[1] *Phil. Trans.*, 1887, vol. clxxviii. B, p. 61. In school-rooms well ventilated by mechanical means these authors found 13 parts of carbonic acid in 10,000 of air, which they consider a limit permissible in rooms of that class, though not in dwelling-rooms.

[2] *Proc. Roy. Soc.*, 1875, vol. xxiii. p. 187.

[3] This estimate is based on the observations of Pettenkofer, Angus Smith, and Parkes.

[4] *Report*, 1861.

[5] See *Études sur la Ventilation*, Paris, 1863; also *Proc. Inst. Mech. Eng.*, 1867, p. 63.

Hospitals......	1200	cubic feet (and upwards).
Middle class houses.........	1000	“ “
Barracks	600	“
Good secondary schools....	500	“
London board schools	130	“
Workhouse dormitories....	300	“
London lodging-houses....	240	“
One-roomed houses[1].........	212	“

To realize the need of provision for ventilation, it is only necessary to compare these figures with those already given for the rate of consumption of air. Taking the lowest permissible degree of purity (10 parts of carbonic acid in 10,000), we see that, if no fresh air were allowed to enter, the dweller in a middle-class house would make the atmosphere of his room unfit for breathing after occupying it for 1 hour, and that the sleeping rooms of the poor would fall below the standard in 13 minutes.

Ventilation by diffusion and by currents of air.

The atmosphere of rooms is changed partly by diffusion, but chiefly by actual currents of air. The experiments of Pettenkofer have shown that air passes to a very sensible extent through the substance of brick walls. In houses built of stone the movement of air through the walls must be insignificant; but, as regards individual rooms, what is chiefly important in this connection is the percolation through dry plaster, causing an exchange of atmosphere to occur between the inside of the room and the space within the lining of the wall, which is generally in communication with other parts of the building and with the external air. In order that the atmosphere of a room should be changed by means of air currents, three things are necessary,—(1) an inlet or inlets for the air, (2) an outlet or outlets, and (3) a motive force to produce and maintain the current. One might think it needless to enumerate such obvious requirements were it not that, in providing appliances which are intended to act as ventilators, one or other of the three essentials is not unfrequently overlooked. In systems which are distinguished by the general name of *mechanical* or *artificial* ventilation special provision is made for driving the air, by fans, or by furnaces, or by other contrivances to be described more fully below. In what is called *natural* ventilation no special appliance is used to give motive force, but the forces are made use of which are supplied by (1) the wind, (2) the elevated temperature of the room's atmosphere, and (3) the draught of fires used for heating. A careful distinction should be drawn between cases in which these motive forces are skilfully taken advantage of, by the use of proper inlets and outlets, to give the best results attainable without special appliances for driving the air, and other cases, unfortunately too common in practice, where the ventilation is left to take care of itself. In a fair comparison of a mechanical with the natural system we should exclude examples in which the ventilation is haphazard, or in which as near an approach to no ventilation is reached as the conditions of modern architecture will permit.

Mechanical and natural ventilation.

Chimney draught.

Domestic Ventilation.—The chief agent in domestic ventilation is the chimney; when a bright fire is burning in an open grate, it rarely happens that any other outlet for foul air from a room need be provided. The column of hot air and burnt gases in the chimney is less heavy, because of its high temperature, than an equal column of air outside; the pressure at the base is therefore less than the pressure at the same level outside. This supplies a motive force compelling air to enter at the bottom through the grate and through the opening over the grate, and causing a current to ascend. The motive force which the chimney supplies has not only to do work on the column of air within the chimney, in setting it in motion and in overcoming frictional resistance to its flow: it has also to set the air entering the room in motion and to overcome frictional resistance at the inlets. In many cases the latter part of the chimney's work is the more considerable of the two. From want of proper inlets air has to be dragged in at a high velocity and against much resistance, under the doors, between the window sashes, and through a hundred other chinks and crevices for which we have to thank imperfect carpentry and half-seasoned timber. Under these conditions the air enters in small streams or narrow sheets, ill-distributed and moving so fast as to form disagreeable draughts, the pressure in the room is kept so low that an opened door or window lets in a deluge of cold air, and the current up the chimney is much reduced. If the attempt is made to stop draughts by applying sand-bags and listing to the crevices at which air streams in, matters only become worse in other respects; the true remedy of course lies in providing proper inlets.[2] The discharge of air by an ordinary open fire and chimney varies widely, depending on the rate of combustion, the height and section and form of the chimney, and the freedom with which air is entering the room. About 10,000 cubic feet per hour is probably a fair average, about enough to keep the air fresh for half-a-dozen persons.[3] Even when no fire is burning the chimney plays an important part in ventilation: the air within an inhabited room being generally warmer than the air outside, it is only necessary that an up-current should be started in order that the chimney should maintain it, and it will usually be found that a current is, in fact, passing up.[4]

Other outlets.

When a room is occupied for any considerable length of time by more than about half-a-dozen persons, the chimney outlet should be supplemented by others, which usually take the form of gratings in the ceiling or cornices in communication with flues leading to the open air. Frequently these openings are protected from down-draught by light flap valves of oiled silk or sheet mica, opening outwards. To increase the efficiency of the ventilating action of the chimney, Dr. Arnott advocated (in 1849) that an opening should be made near the ceiling, into the chimney, guarded by a flap valve of this type, with the object of providing a direct exit for the foul warm air that gathers in the upper region of a room, especially when gas is burnt. To make Arnott's valve of much service it should be larger than the size usually supplied; even then it has the drawback that, notwithstanding the protection given by the valve, enough back flow may occur to blacken the wall and ceiling with soot near the opening. If a valve near the ceiling be provided, it is probably better in most cases to lead its outlet shaft direct to the open air than to lead it into the chimney.

Inlets.

With regard to inlets, a first care must be to avoid such currents of cold air as will give the disagreeable and dangerous sensation of draught. At ordinary temperatures a current of outer air to which the body is exposed will be felt as a draught if its velocity exceeds 2, or at most 3, feet per second. The current entering a room may, however, be allowed to move with a speed much greater than this without causing discomfort, provided its direction keeps it from striking directly on the persons of the inmates. To secure this, it should enter, not horizontally nor through gratings on the floor, but vertically through openings high enough to carry the entering stream into the upper atmosphere of the room, where it will mix as completely as possible with warm air before its presence can be felt. A favorite form of inlet is Sheringham's (see Fig. 1). When opened it forms a wedge-shaped projection into the room, and admits air in an upward stream through the open top. It is usually placed near the ceiling; but a lower place in the wall would be better. Other inlets are made by using hollow perforated blocks of earthenware, called air-bricks, built into the wall; these are often shaped on the inner side like an inverted louvre-board or venetian blind, with slots that slope so as to give an upward inclination to the entering stream.

---

[1] Mean of 29 measurements by Carnelley, Haldane, and Anderson, *loc. cit.*

[2] The absence of proper inlets for air in a house where several fires are burning involves a danger that is much more serious than other effects of bad ventilation. When the air which is required to take the place of that discharged by the chimneys can only struggle in through small openings, the pressure within the house falls considerably below that of the outer air, the water traps under basins and closets are liable to be forced, and foul air is drawn in from every leak in soil-pipe or drain. The writer has found a house drawing what seemed to be its main supply of "fresh" air from the public sewer, through a defective joint between the soil-pipe and the (untrapped) house-drain.

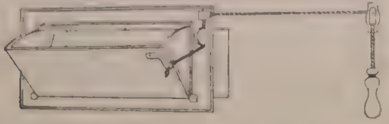

Fig. 1.—Sheringham air inlet.

Tobin tube.

In another and most valuable form of ventilator, the introduction of which is due to Mr. Tobin of Leeds, the fresh air enters vertically upwards. The usual arrangement of Tobin's tube (shown in front elevation and section in Fig. 2) is a short vertical shaft of metal plate or wood which leads up the wall from the floor level to a height of 5 or 6 feet. Its lower end communicates with the outer air through an air-brick or built opening in the wall; from its upper end, which is freely open, the current of fresh air rises in a smooth stream, clinging, as it were, to the wall, and scarcely changing its direction until it has passed far above the level of the opening. Various forms of section may be given to the tube: if placed in a corner it will be triangular or segmental; against a flat wall a shallow rectangular form is most usual; a lining of wood forming a dado may even be made to serve as a Tobin tube by setting it out a little way from the wall. The tube is often furnished with a regulating valve; but this is a doubtful advantage, as it tempts the inmates to stop the ventilation for no better reason than that the room is cold; in exceptional circumstances, such as the presence of an invalid, the opening may be stopped or reduced by laying a board over it. Contrivances are occasionally added for cleansing the entering air. A muslin or canvas bag hung in the tube, or a screen stretched diagonally across it, may be used to filter out dust: the same object is served in some degree by forcing the air, as it enters the tube at the bottom, to pass in close contact with the surface of water in a tray, by means of a deflecting plate. These complications have a double drawback: they require frequent attention to keep them in order and by putting resistance in the way of the stream they are apt to reduce the efficiency of the ventilation.[1] The air entering by a Tobin tube may be warmed by a coil of hot pipes within the tube or by a small gas-stove (provided of course with a flue to discharge outside the products of combustion); or the tube may draw its supply, not directly from the outer atmosphere, but from a hot-air flue or from a room or corridor where the air has been already warmed. The opening should always be about the level of a man's head, but the tube need not extend down to the floor: all that is essential is that it should have sufficient length to let the air issue in a smooth vertical current without eddies (Fig. 3).

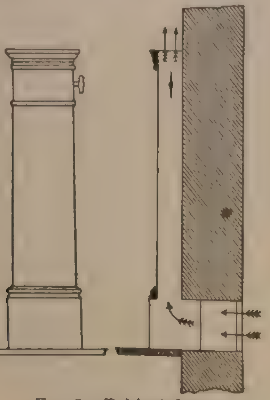

Fig. 2.—Tobin tube.

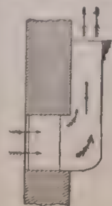

Fig. 3.—Short Tobin tube.

Ventilation by window and door.

These inlets are at once so simple and effective that no hesitation need be felt in introducing them freely in the rooms of dwelling-houses. When no special provision is made for them in the walls, the advantage of a current entering vertically may still be in some degree secured by help of certain makeshift contrivances. One of these, suggested by Dr. Hinkes Bird, is to open one sash of the window a few inches and fill up the opening by a board; air then enters in a zigzag course through the space between the sashes. Another plan is to have a permanent vertical slot between the sashes by making the top of the lower sash stand out a little from the bottom of the upper one. Still another plan is to have a light frame of wood or metal or glass made to fit in front of the lower sash when the window is opened, forming virtually a Tobin's tube in front of the window (see Fig. 4, where a portion of the frame is broken away to show the position of the window sash). This last contrivance allows the fresh air as ready access as may be wished; and, unlike the others, it is still effective when the blind is drawn down. A Tobin's tube, however, is better placed against a dead wall than below a window, for the ascending current is liable to be broken by the window recess and by the down-draught which a window causes by its cooling action on the air of the room. The principle of giving entering currents an upward direction is turned to useful account in a simple contrivance (see Fig. 5) for preventing the disagreeable cold draught which comes along the floor of a room from the chink beneath the door. The clearance under the door is made a little greater than usual, and a thin piece of wood is set on the inner side as close as possible to the floor and at a distance of half an inch or so from the surface of the door; the air then enters in a vertical stream.

Arrangements in barracks;

As an example of the systematic ventilation of dwelling-rooms on a large scale, the following particulars may be quoted of arrangements that have been successfully used in English barracks for more than twenty years. One or more outlet-shafts of wood are carried from the highest part of the room, discharging some feet above the roof under a louvre; the number and size of these shafts are such as to give about 12 square inches of sectional area per head, and the chimney gives about 6 square inches more per head. About half the air enters cold through air-bricks or Sheringham valves at a height of about 9 feet from the floor, and the other half is warmed by passing through flues behind the grate. The inlets taken together give an area of about 11 square inches per head. A fairly regular circulation of some 1200 cubic feet per head per hour is found to take place, and the proportion of carbonic acid ranges from 7 to 10 parts in 10,000.[1]

---

[1] When the air is not filtered, and when it has been warmed before entering, the vertical direction of the stream is readily traced by dust which is deposited on the wall in a nearly upright column, spreading slightly fan-wise as it rises. With cold air the deposit of dust is comparatively slight. The difference is due to the fact noticed and explained by Mr. John Aitken, that air quickly deposits any suspended particles when it is brought into contact with a surface colder than itself but retains them in suspension if the surface be warmer than the air (*Trans. Roy. Soc. Edin.*, vol. xxxiii., 1884, p. 239). Another domestic illustration of the same fact is given by the greater dustiness of walls and furniture in a stove-heated room than in a room heated by an open fire.

In public buildings.

In the natural ventilation of churches, halls, and other large rooms we often find air admitted by gratings in the floor or near it,—an offensive plan, since it fouls the air, besides causing objectionable draughts, unless the temperature is very carefully regulated. The inlets should consist, like Tobin's tubes, of upright flues rising to a height of about 6 feet above the floor, from which the air proceeds in vertical streams. If the air is to be warmed before it enters, the supply may be drawn from a chamber warmed by hot-water or steam pipes or by a stove, and the temperature of the room may be regulated by allowing part of the air to come from a hot chamber and part from outside, the two currents mixing in the shaft from which the inlets to the room draw their supply. If a basement or story below the room to be ventilated is available, a good plan is to carry the inlet tubes vertically down through it and warm the air in them, so that the height of the warm column assists the flow. Outlets usually consist of gratings or plain openings at or near the ceiling, preferably at a considerably distance from points vertically above the inlet tubes. One of the chief difficulties in natural ventilation is to guard them against down-draught through the action of the wind. Numberless forms of cowl have been devised with this object, and often with the further intention of turning the wind to useful account by making it assist the up-current of foul air.

Exhaust cowls.

Some of these exhaust cowls are of the revolving class: a hood or trumpet-shaped mouth, opening horizontally and supported about a vertical axis so as to be free to turn, is kept facing away from the wind by means of a large vane. To make the wind help the up-current, a horizontal conical tube is fixed within the cowl, pointing towards the wind and discharging through the trumpet-mouth of the cowl, where it exhausts by suction, on the principle of the jet-pump. Revolving cowls are liable to fail by sticking, and, apart from that, when the wind blows in shifting gusts they cannot respond quickly enough to its changes of direction to prevent it from occasionally blowing down. Fixed cowls are to be preferred; they are designed in many forms, of which Mr. Buchan's may be cited as a good example. Fig. 6 shows this ventilator in horizontal section: *aa* is the vertical exhaust flue through which the foul air rises; near the top this expands into a polygonal chamber, *bbbb*, with vertical sides, consisting partly of perforated sheet-metal plates; outside of these are fixed vertical curved guide-plates, *c,c,c,c*; the wind blowing between these and the polygonal chamber, sucks air from the centre through the perforated sides. Perhaps no form of cowl is entirely free from liability to down-draughts. The most complete safeguard is to place in the exhaust flue a set of flap-valves opening only outwards. Fig. 7 shows the arrangement of exit-valves employed by Mr. Buchan; the valves *a, a, a* are flaps of oiled silk working on a wooden grid *bb*, which is inclined enough to let them hang free of it when no current is passing; beyond them is a door closing-valve *c*, worked by hand by the cord *d*; and the whole is enclosed in a box, with glass sides *ee*, through which the action of the valves may be seen. When the outlets are guarded by valves of this type they may discharge through a plain box with louvred sides; an exhaust cowl, however, may still be used with advantage to assist the ventilation under favorable conditions of the wind.[2]

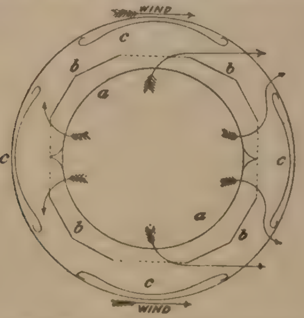

FIG. 6.—Sectional plan of Buchan's exhaust cowl.

The two things that supply motive force in automatic ventilation—the difference of temperature between inner and outer air and the wind—are so variable that even the best arrangements of inlets and outlets give a somewhat uncertain result. To secure a strictly uniform delivery of air, unaffected by changes of season or of weather, the influence of these irregular motive forces must be as far as possible minimized, and recourse must be had to an artificial method of driving the air.

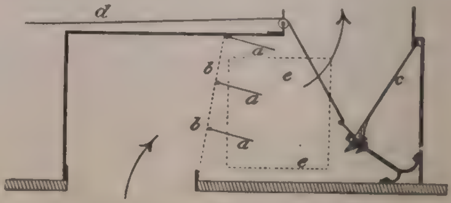

FIG. 7.—Exit valves in exhaust flue.

Artificial ventilation.

Artificial or Mechanical Ventilation.—This finds application on the largest scale in the ventilation of collieries, by methods which are fully described under COAL (vol. vi. pp. 65–67) and MINING (vol. xvi. pp. 480–82). Motive force is supplied to the up-cast shaft either by a furnace at the base, which heats the rising column of air, or (in more modern practice) by a centrifugal fan, such as Guibal's, exhausting air from the top. The long galleries and workings through which the air has to be driven oppose so much resistance that the pressure required to move a sufficient volume of air is immensely greater than is ever necessary or desirable in the artificial ventilation of buildings.

Vacuum and plenum methods.

A broad distinction may be drawn between what are sometimes called vacuum and plenum methods of artificial ventilation. In the former, as in colliery ventilation, the motive force is applied at the outlets: air is drawn from the rooms, and the pressure of their atmosphere is less than the pressure outside. In the latter the motive force is applied at the inlets: air is pushed in, and the pressure within the room is greater than outside. The plenum method has distinct advantages: it makes the air escape instead of coming in as a cold draught at every crevice and casual opening to the outer air; it avoids drawing foul and mouldy air from sewers and basement; and with it, more easily than with the other, one may guard against the disturbing influence of wind. In the plenum method the air is driven by pumps or by fans; in the vacuum method pumps are rarely if ever used: suction is produced by fans or by heating the column of air in a long vertical shaft through which the discharge takes place. Water jets and steam jets have also been employed to impel the air.

Extraction by hot-air shaft.

Extraction by a hot-air shaft is a common mode of ventilating hospitals and other public buildings.[3] Heat is applied by a furnace or stove at the bottom of the shaft, or by coils of hot-water or steam-pipes, which should not extend up the shaft farther than can be helped. In the lecture theatre of the Paris art conservatory, ventilated by Morin, where this means of extraction is employed, fresh air enters through the ceiling and foul air is drawn off through the floor from under the seats; this reversal of the natural direction of the current is of course only possible when a sufficient external motive force is applied. The House of Commons furnishes another example: there the air, after being warmed and moistened, or cooled by water spray, as the state of the atmosphere may require, is admitted through large gratings in the floor, which are covered by porous matting to prevent draughts; outlets from the top of the House lead by flues to the Victoria tower, where a furnace maintains the current in an up-cast shaft.[4] In theatres and other buildings lighted by clusters of gas jets or sun-lights at the ceiling the lights may be turned to account as effective ventilating agents by letting the foul air escape through shafts placed over them, which they heat at the base.[1] What is known in America as the Ruttan or Smead system of ventilation, successfully applied in many schools there, employs a hot-air shaft to furnish motive power. In warm weather a stove at the base of the shaft is used to heat the column; in cold weather the exhaust air from the rooms is so much warmer than the atmosphere outside that the up-cast shaft acts without additional heating. This is in fact an example in which the classification of systems into natural and artificial breaks down. The supply of fresh air is warmed as it enters by passing through chambers containing tubular metal stoves; the outlets are at or near the floor level. A curious feature in the arrangement is that the foul air, in passing to the up-cast shaft, is drawn through the privies, where it desiccates all discharges.

---

[2] For an account of tests of various forms of ventilating cowls, see S. S. Hellyer, *The Plumber and Sanitary Houses*, 4th ed., 1887

[3] For examples, see Morin, *op. cit.*, or *Proc. Inst. Mech. Eng.*, 1867, p. 61.

[4] The arrangements are similar to those introduced by Dr Reid in the temporary Houses of Parliament, and described in his *Treatise on Ventilation and Warming;* see also Tomlinson's *Warming and Ventilation*, p. 265. In recent years pumps have been added, through which air may be forced into the building; but the hot shaft is generally used.

Extraction by fans.

Extraction by fans presents no features requiring special remark. A favorite fan for the purpose is the Blackman propeller, the nearly flat form of which allows it to be readily placed in walls and partitions. One of these fans, 4 feet in diameter, when driven at a speed of about 330 revolutions per minute, is said to discharge 15,000 cubic feet of air per minute with an expenditure of one horse-power. Though this is a good performance, it should be observed that for ventilating purposes, where air has to be driven in large volume with low velocity and under low pressure, fans, while they have the advantage of being less bulky, are less efficient than pumps, for they require that the air in passing through them should move much faster than in other parts of its course, and much of the energy of this motion is wasted in eddies. When fans are used to blow air into buildings, they should deliver into a chamber of considerable size, that the air may become nearly still before it passes into the distributing flues Loss of power may be avoided to some extent by receiving the air in a channel which gradually enlarges as it leaves the fan.

Fans in plenum ventilation.

The plenum method, with fans to drive the air, is exemplified on a large scale in the ventilation of St. George's Hall, Liverpool,[2] where there are four large fans in the basement, driven by a 10-horse-power steam-engine. The building is heated by passing the air through chambers containing coils of hot-water and steam pipes; after the air is warmed it is moistened by injecting steam, and provision is made for washing it by water-spray before it reaches the fans.

When fans are used, either with suction or with pressure, the amount of the current is not strictly independent of those variable motive forces which are the sole agents in natural ventilation; the case is analogous to that of an electric circuit in which several sources of electromotive force are at work, assisting or opposing one another. The fan may be the main agent in circulating the air; but differences of temperature, and at times the action of the wind, may make large variations in the resultant effect. The case is different when pumps are used. A certain quantity of air is delivered at each stroke, and the only effect of these irregular forces is to make the power required to drive the pump sometimes greater and sometimes less. Provided there are no casual inlets and outlets, the amount of air supplied is known with certainty; the ventilation under these conditions is sometimes described as *positive*.

Positive plenum ventilation.

Good recent examples of positive plenum ventilation are to be found in Dundee University College and in a number of Schools in Dundee and Aberdeen, where the arrangements have been designed by Mr. W. Cunningham. Some of these are ordinary double-acting reciprocating pumps, driven generally by water engines. The pumps are rectangular wooden boxes, stiffened by iron ribs, and provided at top and bottom with inlet valves, consisting of a number of short water-proof cloth flaps working against a vertical wooden grid. The piston, which is also of wood, has a vertical travel; it is held in place and worked by wire ropes above and below, which lead over pulleys to the water motor; and the piston is balanced by a counterweight on the descending branch of the upper rope. A piston 5 feet square, with a stroke of five feet, works at 20 strokes per minute and delivers 150,000 cubic feet per hour.

In other instances, where the volume of air is greater than could easily be dealt with by common pumps, Mr. Cunningham uses revolving pumps of the Root's blower type (shown in transverse vertical section through the revolving "pistons" in Fig. 8). At the Dundee College a battery of five of these blowers, each discharging over 150,000 cubic feet of air per hour, is driven easily by a gas engine of two horse-power. The rooms are heated by having coils of Perkins's high pressure hot water pipes in the main distributing flues. The inlets are flat upright tubes extending up the side walls to a height of nearly 6 feet, and open at the top. Ample proof of the advantage that results from giving a vertical direction to the entering current is supplied by the success of Mr. Cunningham's arrangements, where this form of inlet is exclusively adopted. Alternative outlets are generally provided in the end walls, one group near the ceiling, another a few feet from the foot. They are fitted with doors which allow one or other to be closed; the high-level outlets are used in warm weather, when the fresh air that comes in is comparatively cool; the low-level ones are used in cold weather, when the fresh air, having been heated before it enters, would tend to rise and pass out too directly if the outlets near the ceiling were open. The outlet shafts communicate with a louvred tower or turrets on the roof. Each room receives a volume of air equal to its cubic capacity in about 12 minutes, so that the atmosphere is completely changed five times in an hour. The inlets are proportioned to do this without allowing the velocity with which air enters to exceed 6 feet per second.

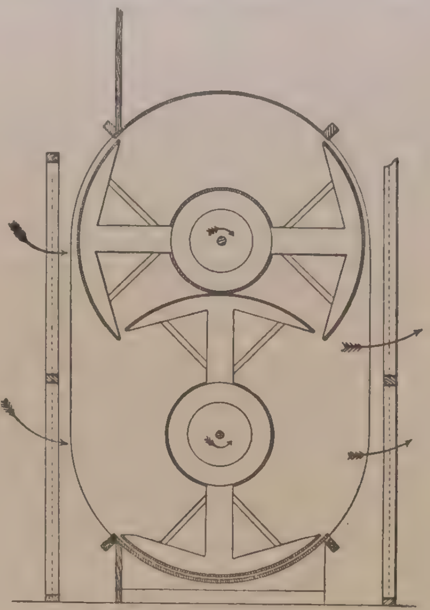

Fig. 8.—Revolving pump for ventilation.

Water-spray ventilator.

The "Æolus" water-spray ventilator of Kind and Mestern is an example of a mechanical ventilator using a jet of water to impel the air. A nozzle at the top of a circular air-shaft delivers a conical sheet of water, which impinges on the sides of the shaft a little way below and carries down with it a considerable stream of air. This ventilator is used either to force air into rooms or to draw it out; in the former case a small gas-stove is often added to heat the supply.

For the ventilation of green-houses and hot-houses, see vol. xii. pp. 236–37.

Organic matter and micro-organisms in air.

The advantage of ample and systematic ventilation is not to be measured only by the low proportion of carbonic acid it secures. Carbonic acid is not the only test of vitiation; it is not even the most dangerous impurity. Another criterion of the foulness of close air is the amount of oxidizable organic matter it contains; still another,—and a most valuable one,—is the number of micro-organisms, especially of bacteria. The micro-organisms may be determined by Hesse's method of slowly passing a given volume of the air to be examined through a tube coated inside with beef jelly; the germs are deposited on the nutrient jelly and each becomes in a few days the centre of a very visible colony. In outside air the number of micro-organisms, as tested in this way, varies greatly: it is often less than 1 per litre (61 cubic inches); in well-ventilated rooms it ranges from 1 to 20; in close school-rooms as many as 600 per litre have been found. The elaborate researches of Carnelley, Haldane, and Anderson[1] on the air of dwellings and schools illustrate well the value of this test. One of the uses to which they have put it has been to compare schools known to be well ventilated (by mechanical means) with schools ventilated at haphazard or not ventilated at all. A large number of trials were made in each case; in the mechanically ventilated schoolrooms the average number of micro-organisms was 17 per litre, and in the others 152. Results of great interest were obtained by the experiment of stopping the mechanical ventilators for a few hours or days. Tested by the proportion of carbonic acid, the air of course became very bad; tested by the number of micro-organisms, it remained comparatively pure, the number being, in fact, scarcely greater than when ventilation was going on, and far less than the average in "naturally ventilated" schools. This proves in a striking way the advantage of systematic ventilation. The bad effect of a foul, stagnant atmosphere is cumulative. An habitually close room acts as a nursery of micro-organisms, which a casual flushing with fresh air will not remove; an habitually well-ventilated room is kept in great measure clear of these dangerous inmates, and its atmosphere may be occasionally overtaxed without causing the number of them to be seriously increased. (J. A. E.)

[2] *Proc. Inst. Mech. Eng.*, 1863, p. 194.

VENTNOR, a watering-place in the southeast of the Isle of Wight, is finely situated in the Undercliff district, at the foot of St. Boniface Down (784 feet), 12 miles south-southwest of Ryde and 10 south-southeast of Newport, with both of which there is communication by coach as well as by rail. The town is finely and picturesquely built on a succession of terraces sloping towards the sea, and from its sheltered situation, equable temperature, and comparatively dry atmosphere is regarded as one of the best resorts in England for consumptive invalids. About fifty years ago it was only a small fishing hamlet; now it extends along the shore for a distance of about 2 miles, including Bonchurch to the east. It possesses assembly rooms and a literary and scientific institution. An esplanade was constructed in 1848, and a pier (645 feet in length) in 1872, which was greatly improved in 1887. There are extensive recreation grounds. The churches are all modern and without special architectural features. The church of St. Boniface at Bonchurch is perhaps the oldest in the island. Among the benevolent and charitable institutions are the royal national hospital for consumptives (begun in 1869), the seaside home of the London city mission, the St. Catherine's home for consumptives, and the convalescent home of the Royal Hants Hospital. An Act for establishing a market was passed in 1844. The town is governed by a board of eighteen members, established in 1858. The population of the urban sanitary district (area 215 acres) was 4841 in 1871 and 5504 in 1881; but there is a considerable population outside the district.

VENUE (from Lat. *vicenetum*) denotes in English law the place from which a jury must be brought for the trial of a case. The word occurs early in constitutional documents, for it was for a long time one of the essentials of trial by jury that the jury should belong to the neighborhood in which the cause of action arose or the alleged crime was committed (see JURY). The phrase *duodecim legales homines de viceneto* or its equivalent is found in the Constitutions of Clarendon (1164), the Assize of the Forest (1184), and in Glanvil. In civil matters venue became after a time divided into local and transitory, the former where the cause of action could only have arisen in a particular county, such as trespass to land, the latter where it might have arisen in any county, such as debt. In the latter case the plaintiff might lay the venue where he pleased, subject to the power of the court or a judge to change it. The law on the subject is now only of antiquarian interest (unless, perhaps, in certain actions on penal statutes), for it is enacted by the Rules of the Supreme Court, 1883 (Ord. xxxvi. r. 1), that there shall be no local venue for the trial of any action, except where otherwise provided by statute. The plaintiff may name his place of trial; where no place of trial is named the place is to be the county of Middlesex. The court or a judge has discretion to alter the place of trial. In criminal practice venue is still of importance, though not as much so as formerly since the large powers of amendment of indictments given by recent legislation. The venue is named in the margin of an indictment in this form, "Middlesex to wit." By 14 and 15 Vict. c. 100 it is unnecessary to state any venue in the body of an indictment, and no indictment is to be held bad for want of a proper perfect venue.

Numerous Acts provide for, *inter alia*, the laying of the venue in the case of offences committed partly in one county and partly in another, or on the high seas, or abroad, and of special offences, such as those under the Post Office, Merchant Shipping, Slave Trade, and Foreign Enlistment Acts. The place of trial may be changed by the Queen's Bench Division, chiefly where it is rendered probable that a fair trial could not be had in the county of the venue.

In Scotch law venue is not used as a technical term; but there are statutory provisions for changing the place of trial in both civil and criminal cases.

In the United States venue may generally be changed by the courts; but in some States it is provided by their constitutions that provision for change of venue is to be made by the legislature. In other States the passing of local or special laws for change of venue is forbidden.

VENUS. See APHRODITE.

VERA, AUGUSTO, (1817–1885), the chief representative of Hegelianism in Italian philosophy, was born at Amelia in the province of Perugia on 4th May, 1817. He completed his education in Paris, and, after teaching classics for some years in Switzerland, was appointed professor of philosophy in connection with the university of France. Attaching himself to Hegel's system with the enthusiasm of a disciple, Vera (who wrote fluently both in French and English as well as in Italian) became widely influential in spreading a knowledge of the Hegelian doctrine. Without any marked originality, his writings are distinguished by the lucidity of their exposition, and by their genuine philosophic spirit. Among his numerous works may be mentioned *Introduction à la Philosophie d' Hégel* (1852, 2d ed., 1864); *Problème de la Certitude* (1861); *Mélanges Philosophiques* (1862); *Essais de Philosophie Hégélienne* (1864); *Strauss, l' Ancienne et la Nouvelle Foi* (1873), an attack upon Strauss's last "confession," written from the standpoint of an orthodox Hegelian; and a comprehensive work in Italian, *Il Problema dell' Assoluto*, belonging to his later years. His English works are an *Inquiry into Speculative and Experimental Science* (1856), more recently an *Introduction to Speculative Logic and Philosophy*, and a translation of Bretschneider's *History of Religion and of the Christian Church*. Vera also translated a number of Hegel's works into French, with introductions and commentaries, including the *Logic*, the *Philosophy of Nature*, the *Philosophy of Spirit*, and the *Philosophy of Religion*. In 1860 Vera returned to Italy, where he was made professor of philosophy in the royal academy of Milan. In the following year he was transferred to Naples as professor of philosophy in the university there. His *Prolusioni alla Storia della Filosofia* and *Lezioni sulla Filosofia della Storia* connect themselves with the work of his chair, which was specially devoted to the history of philosophy and the philosopy of history. He held this post till his death, which took place at Naples in the autumn of 1885.

A Life of Vera, in two volumes, has been published by Signor Mariano, a friend and follower.

VERA CRUZ, a fortified town and seaport of Mexico, formerly capital of the State of Vera Cruz, is situated in 19° 11′ 50″ N. lat. and 96° 20′ W. long., at the southwest corner of the Gulf of Mexico, on a low and exposed seaboard, partly sandy, partly marshy, where the true yellow fever is endemic, prevailing throughout the summer and occasionally breaking out even in winter.[1] The town, which in 1884 had a population of 16,840, is distant 263 miles by rail from Mexico and 60 from Jalapa, the summer residence of the upper classes. It has few buildings of interest, except a superb cathedral decorated in the Moorish style. Most of the streets, which are laid out at right angles, are paved with cobble-stones and have a kennel or open gutter in the middle. A characteristic feature of the place are the turkey-buzzards, who do the scavengering, and are consequently protected by law. The open roadstead, although partly protected by the neighboring islets of Los Sacrificios and San Juan de Ulloa, is greatly exposed to the fierce "nortes" (northers), which sweep over the Gulf at intervals from October to March. A French company, which contracted with the Mexican Government to form a harbor by constructing a breakwater between the islands, has lately suspended operations. Vera Cruz is, however, the largest seaport in the republic. In 1886 over one-half of the exports of Mexico (£3,002,000 [$14,589,720] altogether) were shipped from this place (£1,625,000 [$7,897,500] to Great Britain). Of these exports £2,180,000 [$10,594,800] represented the precious metals, the other chief items being coffee (£207,000) [$1,006,020], hides and skins (£99,000) [$481,140], mineral ores (£84,000) [$408,240], tobacco (£68,000) [$330,480], broom root (£25,000) [$121,500], and sugar (£12,000) [$58,320]. In the same year the imports amounted to £1,941,000 [$9,433,260] (£498,000 [$2,420,250] from Great Britain), and 487 vessels of 295,000 tons cleared from Vera Cruz. In 1887 the exports from Vera Cruz amounted to £1,047,000 [$5,088,420] (coffee £407,000]$1,978,020] and minerals £208,000) [$1,010,880], and the imports to £2,159,000 [$10,492,640].

---

[1] *Phil. Trans.*, 1887, vol. clxxviii. B, p. 61.

The present town of Villa Rica de Vera Cruz ("Rich City of the True Cross") which lies several miles south of the original town founded by Cortes in 1520, was built by the viceroy Monterey at the end of the 16th century, and received the title and privileges of a city from Philip III. in 1615.

The state of Vera Cruz has a seaboard of 450 miles on the Gulf of Mexico, with a mean breadth of 55 miles. Its area is 24,700 square miles, and its total population was 640,000 in 1887, nearly all native Mexicans.

VERATRUM. The Greek physicians were acquainted with a poisonous herb which they called white hellebore, and which has been supposed to represent the existing *Veratrum*. Be this as it may, in modern times the name has been applied to a genus of herbaceous plants closely allied in their structure to *Colchicum*, but differing greatly in general appearance. *Veratrum* is a tall-growing herb, having a fibrous rootstock, an erect stem, with numerous broad, plicated leaves, placed alternately, and terminal much-branched clusters of greenish or purplish polygamous flowers. Each perfect flower consists of six regular segments, as many stamens, whose anthers open outwardly, and a three-celled superior ovary; this last ripens into a three-celled, many-seeded capsule. The genus is included in the order *Melanthaceæ*, otherwise called *Colchicaceæ*, and comprises a small number of species, natives of the temperate regions of the northern hemisphere, generally growing in pastures or woods. Some, and presumably all, contain a violently poisonous alkaloid called veratrin; but, given in small doses and under careful supervision, some of the preparations yielded by *Veratrum* are valuable medicinal agents, their effect being to lower the pulse and the heat of the body. Sabadilla seeds also furnish a drug once in more frequent use than at present. *V. album* and *V. viride* are commonly grown in gardens as ornamental perennials, but their poisonous qualities should be kept in mind, particularly as they bear a considerable resemblance in foliage to the harmless *Gentiana lutea*.

VERBENA. The vervian genus gives its name to the natural order (*Verbenaceæ*) of which it is a member. The species are herbaceous or somewhat shrubby, erect or procumbent, with opposite or whorled leaves, generally deeply cut. The sessile flowers originate in the axils of bracts, and are aggregated into close spikes. Each flower has a tubular, ribbed calyx, a more or less irregular tubular two-lipped corolla, with two or four (didynamous) stamens springing from the centre of the corolla tube. The anthers are two-celled, with or without a gland-like appendage at the apex. The ovary is entire or four-lobed, and always four-celled, with a single ovule in each cell; the two styles are free at the apex only, being elsewhere undivided. The fruit consists of four hard nuts within the persistent calyx. There are about eighty species known, mostly natives of tropical and subtropical America. *V. officinalis*, according to Bentham, is also widely dispersed in the temperate and warmer regions of the eastern hemisphere. *V. bonariensis* occurs in Africa and in Asia, while *V. supina* is indigenous only in the Mediterranean and Canarian regions. The vervein or vervain, *V. officinalis*, a common wild plant on limestone soils in England, was the object of much superstitious veneration on the part of our pagan ancestors, who attributed marvellous properties to it, provided it were gathered in a particular manner and with much complex ceremonial. The plant is now but lightly esteemed, and its medicinal virtues, if it have any, are entirely ignored. The garden verbenas, once so popular for "bedding out," are derivatives from various South-American species, such as *V. teucrioides*, a native of southern Brazil, and *V. chamædrifolia* from Uruguay. The range of colors extends from pure white to rose-colored, carmine, violet, and purple. Striped forms also are cultivated; but of late years the cultivation of these beautiful flowers has been partially abandoned, owing to the prevalence of some ill-understood disease, probably of fungous origin, which has debilitated the plants. The lemon-scented verbena of gardens, so much valued for the fragrance of its leaves, was once referred to this genus under the name *V. triphylla*, subsequently called *Aloysia*, but now referred by Bentham to the genus *Lippia*; it differs from *Verbena* amongst other matters in having two, not four, nuts to the fruit.

VERCELLI, a town of Italy in the province of Novara, lies 14 miles to the southwest of that town, on the river Sesia (here crossed by a bridge), at its junction with the Canterana. The walls by which Vercelli was formerly surrounded have been demolished, and their place is now occupied by boulevards, from which a fine view of the Alps (especially the Monte Rosa group) is obtained. The streets are for the most part tortuous and narrow; there is a large market-place (Piazza Cavour) with a statue of Cavour (1841). The cathedral is a large building dating from the 16th century; its library contains a number of rare ancient MSS., especially the *Codex Vercellensis*, one of the most important MSS. of the old Latin version of the Gospels, written in the 4th century by Eusebius, bishop of Vercelli. The churches of St. Andrew (a Romano-Gothic building dating from 1219–24), St. Paul, St. Catherine, and St. Christopher possess valuable examples of the work of Gaudenzio Ferrari, one of the principal ornaments of the Vercelli school of painting, which flourished in the 15th and 16th centuries, and to which belonged also Giovenoni, Defendente Ferrari, Lanini, and, one may almost add, Bazzi, who was a native of the town. Of the two hospitals of Vercelli one has a museum and botanical gardens; the town also has a lyceum, a gymnasium, a technical school and a seminary. The leading industry is silk-spinning; and there is an active trade in the products of the surrounding district, (silk, hemp, flax and rice). The population in 1881 was 20,165 (commune, 21,169).

---

[1] "The character and extent of yellow fever at Vera Cruz has been very much exaggerated by interested parties—by those established in the port, who do not wish competition on the part of intending settlers, and by those interested in the trade from Vera Cruz to El Paso in the north of the republic" (H. Baker, *Cons. Rep.*, 1886, p. 2).

Vercellæ was originally the chief city of the Libici, and afterwards became a Roman municipium. In the neighborhood (near Rotto on the Sesia) are the Raudii Campi where Hannibal won his first victory on Italian soil (218 B.C.), and where in 101 B.C. Marius and Catulus routed the Cimbri. From about 1228 till 1372 Vercelli was the seat of a university (see Universities).

VERD ISLANDS, Cape. See Cape Verd Islands.

VERDUN, a town of France, chef-lieu of an arrondissement in the department of Meuse, an episcopal see, and a first-class fortress, is situated on the Meuse, 174 miles east-northeast of Paris by the railway to Metz, at the junction of the line from Lérouville to Sedan by the Meuse. The enceinte is pierced by four gates; that to the northeast consists of two crenellated towers, and is an interesting specimen of the military architecture of the 15th century. On the left bank of the river is the citadel, on the site of the old abbey of St. Vannes (10th century), the remaining buildings of which are used as barracks. On all sides the approaches to the place are guarded by an important line of defensive works, including five redoubts and six forts. From afar can be seen the square towers of the cathedral, the exterior of which still recalls the original building of the 11th century. It was burnt in 1047, and reconsecrated in 1147 by Pope Eugenius III. Some interesting buttresses of the 12th century and a crypt of the 11th are worthy of notice. The three naves of the interior have Gothic vaults, separated by modern arches. The town hall (17th century) contains a library (22,500 volumes) and a museum of art, archæology, and natural history. One of the public squares has a statue of General Chevert, a native of Verdun. The town is famous for its confectionery, sugar plums, and liqueurs. In 1881 the population was 15,682 (commune 16,053), and in 1886, 17,282 (commune 17,755).

Verdun (*Verodunum*), an important town at the time of the Roman conquest, was made a part of Belgica Prima. It was destroyed during the period of the barbarian invasions, and did not recover till towards the end of the 5th century. Clovis seized the town in 502, and it afterwards belonged to the kingdom of Austria. In 843 the famous treaty was signed here by the sons of Louis the Pious (see France, vol. ix. p. 471, and Germany, vol. x. p. 431). In the 10th century Verdun was definitely conquered by Germany and put under the temporal authority of its bishops. In the 11th century the burghers of the now free and imperial town began a struggle with their bishops, which ended in their obtaining certain rights in the 12th century. In 1553 Henry II. of France took possession of Verdun, which finally became French by the treaty of Westphalia. In 1792, after some hours of bombardment, the citizens opened their gates to the Prussians,—a weakness which the Revolutionary Government punished by the execution of some young girls who had offered flowers to the king of Prussia. In 1870 the Prussians, unable to seize the town by a *coup de main*, invested and bombarded it three different times, till it capitulated in the beginning of November.

VERGILIUS. See Virgil.

VERGNIAUD, Pierre Victurnien (1753–1793), French orator and Revolutionist, was born on 31st May, 1753, at Limoges. He was the son of a merchant of that town, who lost the greater part of his means by speculation. The boy was early sent to the college of the Jesuits at Limoges, and soon achieved distinction. Turgot was then intendant of Limousin. In his presence young Vergniaud on one occasion recited some verses of his own composition. Turgot was struck with the talent they displayed, and by virtue of his patronage Vergniaud having gone to Paris, was admitted to the College of Plessis. It is impossible to read the speeches of Vergniaud without being convinced of the solidity of his education, and in particular of the wide range of his knowledge of the classics, and of his acquaintance—familiar and sympathetic—with ancient philosophy and history.

Duputy, president of the parlement of Bordeaux, with whom Vergniaud became acquainted, conceived the greatest admiration and affection for him and appointed him his secretary. Vergniaud was thereafter called to the bar (1782). The influence of Duputy gained for him the beginnings of a practice; but Vergniaud, though capable of extraordinary efforts, too often relapsed into reverie, and was indisposed for study and sustained exertion, even in a cause which he approved. This weakness appears equally in his political and in his professional life: he would refuse practice if his purse were moderately well filled; he would sit for weeks in the assembly in listlessness and silence, while the policy he had shaped was being gradually undermined, and then rise, brilliant as ever, but too late to avert the calamities which he foresaw. In 1789 Vergniaud was elected a member of the general council of the department of the Gironde. Being deeply stirred by the best ideas of the Revolutionary epoch, he found a more congenial sphere for the display of his great powers in his new position. About this period he was charged with the defence of a member of the national guard of Brives, which was accused of provoking disorders in the department of La Corrèze. Abandoning all reserve, Vergniaud delivered one of the great orations of his life, depicting the misfortunes of the peasantry in language of such combined dignity, pathos, and power that his fame as an orator spread far and wide.

By the self-denying ordinance of the constituent assembly France was deprived of the whole talent and experience of its members in that new body — the legislative assembly — for which they were declared ineligible; and the election of new men was proceeded with. Vergniaud was chosen a representative of the Gironde in August, 1791, and he forthwith proceeded to Paris. The legislative assembly met on 1st October. For a time, according to his habit, he refrained from speaking; but on 25th October he ascended the tribune, and he had not spoken long before the whole assembly felt that a new power had arisen which might control even the destinies of France. This judgment was re-echoed outside, and he was almost immediately elected president of the assembly for the usual brief term. Between the outbreak of the Revolution and his election to the legislative assembly the political views of Vergniaud had undergone a decided change. At first he had lauded a constitutional monarchy; but the flight of Louis filled him with distrust of the sovereign, and his views in favor of a republic were rapidly developed. The sentiments and passions which his eloquence aroused were, however, watchfully utilized by a more extreme party. It happened thus even with his first assembly speech, on the *émigrés*. His proposal was mainly that a treble annual contribution should be levied on their property; but the assembly confiscated their goods and decreed their deaths. One great blot on his reputation is that step by step he was led on to palliate violence and crime, to the excesses of which his eyes were only opened by the massacres of September, and which ultimately overwhelmed the party of Girondists which he led. The disgrace to his name is indelible that on 19th March, 1792, when the perpetrators of the massacre of Avignon had been introduced to the assembly by Collot d'Herbois, Vergniaud spoke indulgently of their crimes and lent the authority of his voice to their amnesty. In language, sometimes turgid, but nearly always of pure and powerful eloquence, he worked at the theme of the *émigrés*, as it developed into that of the counter-revolution; and in his occasional appearances in the tribune, as well as in the project of an address to the French people which he presented to the assembly on 27th December, 1791, he shook the heart of France, and, especially by his call to arms on 18th January, shaped the policy which culminated in the declaration of war against the king of Bohemia and Hungary on 20th April. This policy in foreign affairs, which he pursued through the winter and spring of 1791–92, he combined with another,—that of fanning the suspicions of the people against the monarchy, which he identified with the counter-revolution, and of forcing on a change of ministry. On 10th March Vergniaud delivered a powerful oration in which he denounced the intrigues of the court and uttered his famous apostrophe to the Tuileries: "In ancient times fear and terror have often issued from that famous palace, let them re-enter it to-day in the name of the law!" The speech overthrew De Lessart, whose accusation was decreed; and Roland, the nominee of the Girondists, entered the ministry. By the month of June the opposition of Vergniaud (whose voice still commanded the country) to the king rose to fever heat. On 29th May Vergniaud went so far as to support the disbanding of the king's guard. But he appears to have been unaware of the extent of the feelings of animosity which he had done much to arouse in the people, probably because he was wholly unconnected with the practices of the party of the Mountain as the instigators of actual violence. This party used Vergniaud, whose lofty and serene ideas they applauded and travestied in action. Then came the riot of the 20th of June and the invasion of the Tuileries. He rushed among the crowd, but was powerless to quell the tumult. Continuing for yet a little longer his course of feverous, almost frenzied, opposition to the throne, on 3d July he electrified France by his bold denunciation of the king, not only as a hypocrite and a despot, but as a base traitor to the constitution. His speeches breathe the very spirit of the storm, and they were perhaps the greatest single factor in the development of the events of the time. On the 10th of August the Tuileries were stormed, and the royal family took refuge in the assembly. Vergniaud presided. To the request of the king for protection he replied in dignified and respectful language. An extraordinary commission was appointed: Vergniaud wrote and read its recommendations that a national convention be formed, the king be provisionally suspended from office, a governor appointed for his son and the royal family be consigned to the Luxembourg. Hardly had the great orator attained the object of his aim, the overthrow of Louis as a sovereign, when he became conscious of the awful forces by which he was surrounded and his eyes were opened to the infamy of their régime.

The terrible revelation silenced him for a time. But the massacres of September again unchained his eloquence. He denounced the massacres—their inception, their horror, and the future to which they pointed—in language so vivid and powerful that it raised for a time the spirits of the Girondists, while on the other hand it aroused the fatal opposition of Robespierre and of his followers within and without the convention.

The questions whether Louis XVI. was to be judged, and if so by whom, were the subject of protracted debate in the convention. They were of absorbing interest to Paris, to France, and to Europe; and upon them the Girondist leader at last, on 31st December, 1792, broke silence, delivering one of his greatest orations, probably one of the greatest combinations of sound reasoning, sagacity, and eloquence which has ever been displayed in the annals of French politics. He pronounced in favor of an appeal to the people. He pictured the consequences of that temper of vengeance which animated the Parisian mob, and was fatally controlling the policy of the convention, and the prostration which would ensue to France after even a successful struggle with a European coalition, which would spring up after the murder of the king. The great effort failed; and four days afterwards something happened which still further endangered Vergniaud and his whole party. This was the discovery of a note signed by him along with Gaudet and Gensonné and presented to the king two or three weeks before the 10th of August. It contained nothing but sound and patriotic suggestions; but it was greedily seized upon by the enemies of the Gironde as evidence of treason. On 16th January, 1793, the vote began to be taken in the convention upon the punishment of the king. Vergniaud voted early and voted for death. The action of the great Girondist was and will always remain inscrutable; but it was followed by a similar verdict from nearly the whole party which he led. On the 17th Vergniaud presided at the convention and it fell to him, laboring under the most painful excitement, to announce the fatal result of the voting. Then for many weeks he sank, exhausted, into silence.

When the institution of a revolutionary tribunal was proposed by the Robespierrists, Vergniaud vehemently opposed the project, denouncing the tribunal as a more awful inquisition than that of Venice, and avowing that his party would all die rather than consent to it. Their death by stratagem had already been planned, and on 10th March they had to go into hiding. On the 13th Vergniaud boldly exposed the conspiracy in the convention, taking occasion to discuss the profanation by the extremists of the name of liberty, and distinguishing between a true and spurious equality, employing with reference to the latter his famous simile of the bed of Procrustes. The antagonism caused by such an attitude had reached a significant point when on 10th April Robespierre himself laid his accusation before the convention. He fastened especially upon Vergniaud's letter to the king and his support of the appeal to the people as a proof that he was a moderate in its then despised sense. Vergniaud made a brilliant extemporaneous reply, and the attack for the moment failed. But now, night after night, Vergniaud and his colleagues found themselves obliged to change their abode, to avoid assassination, a price being even put upon their heads. Still with unfaltering courage they continued their resistance to the dominant faction, till on the 2d of June, 1793, things came to a head. The convention was surrounded with an armed mob, who clamored for the "twenty-two." In the midst of this it was forced to continue its deliberations. The decree of accusation was voted, and the Girondists were proscribed.

Vergniaud was offered a safe retreat. He accepted it only for a day, and then returned to his own dwelling. He was kept under surveillance there for nearly a month, and in the early days of July was imprisoned in La Force. He carried poison with him, but never used it. His tender affection for his relatives abundantly appears from his correspondence, along with his profound attachment to the great ideas of the Revolution, and his noble love of country. On one of the walls of the Carmelite convent, to which for a short time the prisoners were removed, Vergniaud wrote in letters of blood—"Potius mori quam fœdari." Early in October the convention brought forward its indictment of the twenty-two Girondists. They were sent for trial to the Revolutionary tribunal, before which they appeared on the 27th of October. The procedure was a travesty of justice. Conscious of innocence, but certain of death, Vergniaud preserved silence, and his example was largely followed by his companions.[1] By the end of the fourth day of trial it became evident that the demeanor of the prisoners was touching the hearts of the people and making them relent. Then suddenly came the order from the alarmed committee of safety to bring the proceedings to an end. Gensonné demanded to be heard in defence of the prisoners. This was refused; a verdict of guilty followed and a sentence of death. Valazé stabbed himself to the heart and fell dead among his comrades. They were conducted to the conciergerie, which they entered singing the Marseillaise. Early on the following morning, 31st October, 1793, they were conveyed to the scaffold, again singing on the way

[1] [They agreed together each to defend his own case and Vergniaud spoke first and with great eloquence. See Carlyle's *French Revolution*, iii, iv. 8 ch.—AM. ED.]

the national chant, and keeping up the strain till one by one they were guillotined. Vergniaud was executed last. (T. S.)

VERKHNE-URALSK, a district-town of Orenburg, Russia, at the eastern base of the Ural Mountains and on the upper Ural river, 380 miles northeast of Orenburg, is rapidly becoming an important centre of trade with the Bashkirs and Kirghiz in honey, wax, wool, hides, horses, and sheep. The population (10,354 in 1882) has doubled within the last twenty-five years.

VERMIGLI, PIETRO MARTIRE (1500–1562), commonly known as PETER MARTYR, a reforming theologian of the 16th century, came of a good Tuscan family, and was born at Florence on 8th September, 1500. In 1516 he entered the house of the Augustinian canons regular at Fiesole, and from 1519 onwards studied at Padua, where he heard lectures on the Aristotelian philosophy and taught himself some Greek. In his twenty-sixth year he was sent out as a preacher, in which capacity he visited various Italian cities,—among them Bologna, where a Jewish physician gave him lessons in Hebrew. While prior of St. Peter ad Aram in Naples he was introduced to Juan de Valdes's circle, and also became intimate with Bernardino Ochino. At Lucca, whither he had gone to be prior of San Frediano, the "evangelical" tone of his preaching attracted the attention of the Inquisition, and he was compelled to quit Italy (1542). After short halts at Zurich and Basel he settled in Strasburg as professor of Old Testament exegesis, and in 1547 he removed to England, mainly at Cranmer's instance. During the next six years he taught exegesis as a professor in Oxford, conducted public disputations, took part in the adjustment of the Book of Common Prayer, and was generally active in the theological discussions of the time. The accession of Queen Mary in 1553 obliged him to leave England, and he resumed his former duties at Strasburg. From 1555 till his death in the autumn of 1562 he taught in Zurich. He took a prominent part in the abortive conference of Poissy in 1561.

His Oxford lectures on 1st Corinthians were published at Zurich in 1551 and those on the Romans at Basel in 1558, In 1559 appeared his *Defensio doctrinæ veteris et apostolicæ de S. Eucharistiæ sacramento*, and also his *Defensio ad R. Smythæi duos libellos de cœlibatu sacerdotum et votis monasticis.* The *Dialogus de utraque Christi natura* dates from 1561; and after his death a number of his commentaries on books of the Old Testament were published by his friends. In 1575 Robert Masson, a French preacher in London, published a folio volume of *loci communes* from Martyr's writings, digested according to the method of Calvin's theological system. This is a work of great value to students of the Reformation theology. A number of interesting letters by Martyr to prominent theologians are also extant.

See Schlosser's *Leben des Th. Beza u. des P. M. Vermigli* (Heidelberg, 1807) and C. Schmid's *Leben der Väter u. Begründer der reformirten Kirche*, vol. vii. (Elberfeld, 1858).

VERMILION is a brilliant scarlet pigment composed of the sulphide of mercury, HgS. To a small extent it is obtained direct from pure and bright-colored portions of the native ore CINNABAR (*q.v.*); but it is chiefly an artificial preparation. The process of manufacture, as conducted principally in Holland, consists in making an intimate mixture of mercury with about one-sixth of its weight of sulphur, and these under the influence of a gentle heat combine to form the black sulphide of mercury called æthiop's mineral. In successive portions pieces of this compound are thrown into tall earthen pots the lower parts of which are kept at a red heat, and the mass sublimes, depositing a coating of artificial cinnabar on the iron covers and over the upper part of the pots themselves. At the end of the subliming process, the pots are broken, the deposit of cinnabar is scraped off, ground in a mill, levigated, and when dry it is ready for use as vermilion. The pigment is also prepared by the wet method (see MERCURY, vol. xvi. p. 38), and it is said that Chinese vermilion owes its superiority to being made in this way. In addition to its brilliance, vermilion is a pigment of great intensity and durability, remaining unaffected by acid fumes. Being costly, it is much subject to adulteration; but the fraudulent additions may easily be detected by volatilization, which in the case of pure vermilion leaves no residue. For antimony vermilion, see PIGMENTS, vol. xix. p. 96.

VERMONT, one of the New England States of the American Union, lies between 42° 44′ and 45° 0′ 43″ N. lat. and 71° 38′ and 73° 25′ W. long. It is bounded on the N. by the Canadian province of Quebec, on the E. by New Hampshire, from which it is separated by the Connecticut river, on the S. by Massachusetts, and on the W. by New York, from which it is separated for more than 100 miles by Lake Champlain. The Canadian boundary is 90 miles long; but from this the width of Vermont continually grows less towards the southern border, where it is 41 miles. The length is 158 miles. The boundary between Vermont and New York passes through the western side of Lake Champlain, so that three-fourths of the lake and most of its islands belong to the former. The area of the State is 10,212 square miles.

Plate V.

Physical features.

The surface is greatly diversified, so that the scenery is everywhere attractive and often grand. The Green Mountains, following a southwesterly trend, divide the State into nearly equal portions. Near Canada there are two ranges, the western being the larger; but near the forty-fourth parallel they unite and continue through western New England as a single range. The highest mountain is Mansfield (4430 feet), and there are five others over 4000 feet and twelve over 3500 feet. Except upon the loftiest summits, the whole range is densely covered with forests of spruce (*Abies nigra*), mingled with which are other evergreen and deciduous trees.[1] Many of the streams flowing west unite to form five rivers which enter Lake Champlain. Eleven smaller rivers flow into the Connecticut, which drains about one-third of the area of Vermont. Three streams run north and enter Lake Memphremagog, about one-fifth of which is within the State, and two flow south to join the Hudson river. Most of the larger streams pass through wide, fertile valleys. Small lakes and ponds are abundant.

Geology.

The rocks of Vermont are largely metamorphic. Their age has long been disputed among geologists; it appears now, however, to be clearly established that most of them are Palæozoic, although there are a few small areas which may prove to be Archæan. Along Lake Champlain there are many outcrops of unaltered fossiliferous strata, which, from the Lower Cambrian through the Hudson River or Cincinnati formations, lie in a regular conformable series, and upon these rest Quaternary deposits. The strata have a northerly strike and a dip 5°–90° E. They form frequent headlands and cliffs upon the shore of Lake Champlain, where they can be most easily studied. The Cambrian beds, nowhere more than a few miles broad, extend from Canada southwards for about 90 miles, having a total thickness of probably not less than 10,000 feet. They consist of limestone, sandstone, shale, slate, quartzite, and conglomerate. The limestone is often arenaceous and dolomitic, sometimes magnesian. There are great masses of reddish, silicious limestone, the Red Sandrock of geologists, which, often destitute of fossils, contains here and there species of *Ptychoparia*, *Olenellus*, *Orthisina*, *Obolus*, *Salterella*, etc. Included in these beds are thick layers of a beautifully mottled red and white dolomite, the "Winooski marble," long used for architectural purposes. Similar fossils occur in the "Georgia shales" and elsewhere. Above the Cambrian are small patches of Calciferous and Quebec, then larger areas of Chazy, Trenton, Utica, and Hudson River. In the Chazy and Trenton there are extensive

---

[1] Hence the old French name *Verd Mont.*

quarries upon Isle la Motte, and these formations are finely exhibited in many localities near the lake. The rocks are mostly limestones and shales of a black or dark gray color, and frequently afford Silurian fossils in great abundance. Within a few miles of Lake Champlain the sedimentary rocks are replaced by schists, quartzites, and other metamorphic rocks, which continue beyond the mountains to Connecticut river. In the southern part of Vermont there are Lower Helderberg strata, and in the northern, about Lake Memphremagog, Upper Helderberg. These occupy but limited areas and are unconformable with the underlying rocks. Rev. A. Wing determined the age of the great marble beds of Rutland county to be mostly, if not wholly, of the Chazy epoch. He then extended his observations to the rocks of the Green Mountain mass; and by means of the results thus gained, as well as by his own long-continued independent researches, Prof. J. D. Dana seems to have substantially settled the age of the rocks which compose the mountains as Lower Silurian, and shown that the uplift ending in the range took place after the close of the Hudson River and before the Helderberg period. In the Champlain valley the rocks are traversed by dikes of trap and porphyry, which in some instances have spread over the strata. In the Utica and Hudson River shales there is most beautiful veining; innumerable seams of white calcite, from the finest line to several inches in width, cross and recross the black strata in every direction. In a narrow strip from Canada to Bennington there are Tertiary beds, which are well seen at Brandon. In this formation there are great masses of lignite, containing fossil fruits, also bog iron, manganese, kaolin, and variously and often brightly colored clays. The entire surface of Vermont shows the effects of glaciations. Some of the Silurian ledges are striated and polished most beautifully. Drift, boulders, sands, clays occur everywhere; every stream is bordered by terraces; remains of mammoth, mastodon, beluga, are found in the drift deposits, as well as *Mya*, *Saxicava*, *Mytilus*, and other marine *Mollusca*. Sea-beaches over 2000 feet and terraces over 1000 feet above the present sea-level testify to movements of the surface. From the early Cambrian to the late Quaternary epoch Lake Champlain was an arm of the sea, and for a portion of this time it was connected with the ocean at each end, so that a current flowed from what is now New York Bay to St. Lawrence Gulf, converting New England into an island.

Minerals.

Ores of copper, silver, lead, gold, manganese, and iron occur; but, although numerous attempts at mining have been made, very few have continued or ever been profitable. A large amount of copper is obtained at the Ely mines, where the ore is chalco-pyrite; and gold has been found in paying quantity in river gravel, and also in veins, and is still sought in one or two places. The chief mineral wealth of the State is in its quarries. No other State in the Union produces so great a variety or quantity of marble. The annual production is nearly 2,000,000 cubic feet, and is increasing. Roofing and other slate is obtained in very large quantities and of fine quality. Most excellent granite is quarried in increasing amount, and there are large beds of soap-stone, which are worked. Besides what may be called useful minerals, the State affords a large variety of species, *e.g.*, rutile, actinolite, talc, serpentine, which are of interest to the mineralogist. The State has many mineral springs, some of which have long been places of popular resort. Most of them are sulphurous, some chalybeate, carbonate, or alkaline.

Climate.

The climate of Vermont, like that of New England generally, is subject to extremes and to sudden changes. In summer the temperature varies from 65° to 75° Fahr., sometimes rising to 90°; in winter it ranges from 18° to 50°, sometimes falling to —10° or rarely —20°. At Burlington the mean annual temperature is 45°. The climate is milder in the Champlain valley than east of the Green Mountains. During the winter there is often much snow, which in the colder parts of the State covers the ground for three months. The average annual rainfall is 33 inches. The air is clear and pure. Notwithstanding the changeable climate, the death-rate is low and the people robust.

Fauna.

Most of the large mammals formerly common, — the panther, wolf, lynx, beaver, otter, moose,—have either disappeared or are very rare; others, as the black bear, red deer, mink, and marten, are found only in certain localities. More common are the red fox, raccoon, skunk, porcupine, woodchuck, rabbit, squirrel, and other smaller species. Birds have changed less; but the wild turkey, golden eagle, raven, etc., have become very rare, and the white-headed eagle, large hawks, owls, herons, bitterns, and the like are far from common. The lakes are visited at certain seasons by great numbers of ducks, geese, and other water-fowl. Thrushes, blue-birds, titmice, sparrows, swallows, warblers, vireos, blackbirds, crows, and woodpeckers are common, as well as many other small birds. In Lake Champlain and the large streams which flow into it are found sturgeon, garpike, muskalonge, bass, pike, pickerel, shad, as well as many smaller species. Trout abound in the mountain streams and in some of the ponds. Reptiles and batrachians are not numerous either in species or individuals.

Flora.

The flora is of great beauty and of unusual botanical interest. *Saxifraga Aizoon*, *Poa laxa*, *Arenaria grœnlandica*, and other alpine plants are found on the higher mountains. *Lathyrus maritimus*, *Hudsonia tomentosa*, and other maritime species recall the time when Lake Champlain was salt. A number of western species find their eastern limit in the Champlain valley, and a greater number of Canadian plants have ended their southward migrations in northern Vermont. Over 1300 species of phanerogams and higher cryptogams grow wild in the State. About 50 of these are found nowhere else in New England, and a few nowhere else in the United States. Ferns grow luxuriantly in many mountain forests and ravines, where 50 species may be collected, including such very rare forms as *Asplenium viride*, *Pellæa gracilis*, *Woodsia glabella* and *hyperborea*, *Aspidium Braunii*, etc. Orchids are also abundant. Of the 108 families found in the State the most numerous are the ranunculus, saxifrage, rose, composite, heath, lily, grass, and sedge. The once prevalent forests are now chiefly confined to the mountains. There are nearly 100 species of trees and large shrubs; the forests and groves consist chiefly of 11 species of oak, 6 of maple, 17 of willow, 6 of birch, 8 of poplar, 3 of elm, 17 of conifers, besides beech, ash, walnut, butternut, etc. No single species forms so characteristic a feature of the landscape as the American elm, which with great variety of form, always elegant and beautiful, grows singly or in small groups in every meadow and upon many uplands. The sugar maple is a common and conspicuous tree. (G. H. P.)

Population.

The population was estimated in 1777 at 30,000. The first census taken, in 1791, gave 85,425. The different enumerations from 1800 to 1880 inclusive have been as follows: 154,465; 217,895; 235,966; 280,652; 291,948; 314,120; 315,098; 330,551; 332,286. The very slight gain in the decades succeeding 1850 is accounted for by the large emigration from Vermont to the western portions of the country. Of the total population in 1880, 291,327 were natives and 40,959 foreign born. Of the latter class British America furnished the largest contingent, 24,620; Ireland, 11,657; other parts of Great Britain, 3773. The number of colored was 1057; the excess of males over females, 1488. The number gathered in towns of from 4000 to 12,000 inhabitants was 37,800. The largest towns are Rutland, 12,149 (in 1886 two new towns were formed from it); Burlington, 11,365; St. Albans, 7193; Bennington, 6333; Brattleboro, 5880; St. Johnsbury, 5800. Montpelier, the capital, has 3219. The average density of population is 36.4 per square mile. The insane numbered 1015; idiotic, 803; blind, 486; paupers, 1564; inmates of prisons and reformatories, 261. The births in 1885 were 6592, or 22.1 per 1000 of population, and the deaths 5358 (average age as reported, 41.95 years; percentage of deaths to population, 1.61). The number of divorces in 1860 was 94, one to every 23 marriages; in 1880 the number was 129 (one to 20 marriages); and in 1885 it was 94 (one to 28.7 marriages).

Agriculture.

Agriculture is the chief occupation of the State. The 35,522 farms make up a total of 4,882,588 acres, of which 3,286,461 are improved land. The western portion of the State contains the finest tracts of arable land; the climate as well as the soil of the Champlain valley is especially adapted to fruit-raising, the surface of the lake being but 90 feet above sea-level. The average size of farms in Vermont is 137 acres; the total estimated value of the farms in 1880 was $109,346,010, and of the total products in 1879 $22,082,656. Subjoined are the figures relating to the leading crops: wheat, 337,257 bushels, averaging 16.28 bushels per acre; oats, 3,742,282 bushels, averaging 37.6 bushels per acre; Indian corn, 2,014,271; potatoes, 4,438,172 bushels; hay, 1,051,183 tons.

The wool clip was 2,551,113 ℔; and there were 217,033 cows, producing 25,245,826 ℔ of butter (12,137,980 ℔ in 1850) and 6,121,130 ℔ of cheese (8,720,834 in 1850). The value of orchard products amounted to $640,942. Of maple sugar Vermont produces more than any other State,—in 1880 11,261,077 ℔, or 30.8 per cent. of the whole production of the United States, besides 128,091 gallons of molasses.

Live stock. In 1880 the State possessed 75,215 horses, 283 mules and asses, 18,868 working oxen and 167,204 other cattle (exclusive of milch cows), 439,870 sheep, and 76,384 pigs. Much attention is given to the raising of improved stock. The rearing of fine breeds of sheep for exportation is a lucrative business.

Fisheries. Lake Champlain abounds in fish of various kinds. Great pains have been taken of late years to stock the numerous ponds and streams of the State with salmon, trout, carp, and bass. Both fish and game are protected by stringent laws, and to some extent by special police supervision.

Manufactures. In 1880 there were 2874 manufacturing and mechanical establishments, the average number of operatives 17,540, and the value produced in 1879 was $31,354,366. Eight firms manufactured cotton, 44 woollen goods, 227 flour and grist-mill products, 56 furniture, 77 leather, 95 tin-ware, copper-ware, etc., 35 agricultural tools, and 706 lumber. The State rates as nineteenth in value ($3,258,816) of lumber products, while Burlington ranks third in importance among the lumber markets of the United States. Eighteen marble quarries produced a value of $1,340,050; there are also granite and slate quarries,—61 quarries in all, with a total production in 1879 of $1,752,333.

Commerce. Burlington is the only port of entry. The State has 9 steam vessels aggregating 2380 tons, 12 sailing vessels, and 14 unrigged vessels, the total tonnage being 4594. The imports for the year ending 31st December, 1887, were $5,959,813 and the exports $1,433,564; the value of the pine, spruce, and hemlock lumber imported was $1,084,599. Most of this foreign trade is carried on with Canada.

Railways. Railroad construction was begun in 1846, and by December, 1849, two lines were completed from the Connecticut river to Burlington. In 1853 the working mileage had risen to 493 miles, and in 1886 it was 946 miles, mainly of trunk lines. A State board of three commissioners, appointed by the governor and senate, exercises general supervision.

Finance. Bills of credit were issued as early as 1781, and were all faithfully redeemed. The first State bank was chartered in 1806, but closed an unsuccessful career in 1814. In 1818 banks were established at Windsor and Burlington. In 1841 there were 17 incorporated banking institutions, with a capital of $1,735,000. In October, 1887, there were 49 national banks, with an aggregate capital of $7,566,000, a surplus fund of $1,571,864, and $668,329 undivided profits. The circulation was $3,478,100, secured by bonds to the amount of $3,891,000. The loans and discounts amounted to $12,879,765, and the individual deposits to $6,627,090. In 1860 there were 12 institutions for savings, with deposits to the amount of $1,111,532. In June, 1887, there were 28 savings banks and trust companies, with $15,587,051 to the credit of 53,810 depositors, and a surplus of $776,113. Deposits pay a state tax of $\frac{6}{10}$ per cent. The State proper has no debt.

Religion. The Congregationalists have 197 churches, 186 ministers, 20,271 members, 22,035 pupils in Sunday schools, and 13,748 families belonging to the congregations. The Baptists have 105 churches, 111 ministers, 8623 members, 8922 pupils in Sunday schools. The Methodists have 192 churches, 161 ministers, 16,067 members, 18,830 children in Sunday schools. The Episcopalians report 36 ministers in charge of 52 parishes, with 3926 communicants; number of families, 1789. The Free Baptists and Christians together have 60 churches and 4000 members; the Adventists 35 churches with 1750 members. The Roman Catholics have 39 priests in charge of 79 churches and number about 25,000.

Education. Lands were set apart for the support of schools by the proprietors of townships as early as 1761. Legislative provision for education dates from 1782. The original educational system of the State contemplated primary schools in every township, a grammar or high school in each county, and one university. Towns were authorized to subdivide into districts of convenient size, each with power to choose its own officers, levy taxes, and maintain a school. In 1870 the towns were authorized to substitute the town for the district system, but in 1886 only one in nine had made the exchange. In 1886 there were 2557 public schools of all grades, with 71,667 pupils, besides 7247 in private schools. In 1880 the number of persons above ten years unable to read was 12,993, or 4.9 per cent, the population between 5 and 20 being 99,463. The total revenue for school purposes in 1886 was $621,370. This revenue is derived partly from funds held by the State, but chiefly from town and district taxes. Facilities for advanced instruction are offered by 39 public high schools and 25 incorporated academies. The State has 3 normal schools founded in 1866. Since 1874 State supervision is exercised through a superintendent elected by the general assembly. The State university at Burlington, chartered in 1791, was inaugurated in 1800; it provides instruction in arts, engineering, chemistry, agriculture, and medicine, with a teaching staff of 15 in the academic and 26 in the medical faculty; in 1887 there were 189 students in medicine, 148 in arts and sciences, and in all departments 487. The library contains 35,300 volumes. Middlebury College (Congregational), chartered in 1800, has a teaching staff of 9 with 63 students, and a library of 16,000 vols. Norwich university (Episcopalian) at Northfield is organized as a military school; there are 10 instructors and 56 students. The State library contains 18,600 vols., the free public library of Burlington 18,000 vols., that of St. Johnsbury 12,000, and that of Lunenburg (free but not public) 14,000. In all 75 libraries were reported in 1880, 42 having over 1000 vols. each.

Administration. The governor and chief executive officers are elected by direct vote of the male citizens twenty-one years old and upwards who have resided within the State for one whole year preceding the election. The general assembly, or legislative body, is composed of a senate of 30 members apportioned among the 14 counties according to population, and a house of representatives consisting of one member from each organized township (244). The sessions of the legislature have been biennial since 1870. The State election occurs in September in the even years. The judiciary is elective throughout, the chief justice and 6 assistant justices of the supreme court being chosen by the senate and house in joint assembly. The term of service is usually a long one by virtue of repeated re-elections. The assistant judges of county courts are chosen by the freemen of the counties, and justices of the peace by the several towns. The county courts hold two terms annually, a justice of the supreme court presiding. A general session of the supreme court is held at the capital in October or November. Probate courts are held in each county, six of the counties being divided each into two probate districts. The State is represented in the Federal Government by two senators and two representatives, and has four votes in the electoral college. Since 1852 the policy of the State in regard to intoxicating liquors has been that of prohibition.

History. *History.*—Vermont first became known to Europeans in 1609, when Champlain explored the lake since known by his name. During the next century the lake and its borders were a thoroughfare for various military expeditions in the Indian and colonial wars, and several points along the lake were occupied, mainly as military posts, by both French and English; but the first permanent settlement was made in 1724 at Fort Dummer in the limits of Brattleboro. In 1760 there were not more than 300 inhabitants, scattered along the Connecticut river within 50 miles of the southern border. Both New Hampshire and New York claimed jurisdiction over the territory under royal grants (see vol. xvii. p. 403). By 1763 New Hampshire had chartered 138 townships west of the Connecticut, and between 1765 and 1776 New York had issued grants of land, covering in all 2,418,700 acres, often embracing the same territory as the New Hampshire charters. The claims of New York were always stoutly, and sometimes forcibly, resisted by the great majority of the settlers. In 1776 the Vermonters sought admission to the provincial Congress, but through the influence of New York were refused. In January, 1777, they proclaimed their independence, framed a State constitution, and again applied for a place in the confederacy. Congress hesitated as before. In 1780 British generals made overtures to the little republic, but with no result beyond a diplomatic intercourse continued until 1783, so managed by the envoys of Vermont as to gain time and save the State from invasion. In 1782 they knocked at the doors of Congress again without avail. By July, 1789, New York was willing to waive its pretensions, and Vermont was admitted as the fourteenth State in March, 1791. In May, 1775, the "Green Mountain boys" under Ethan Allan and Seth Warner had captured Ticonderoga and Crown Point. The battle of Bennington in August, 1777, was won by the combined forces of Vermont and New Hampshire. During the whole struggle the State, though unrecognized, contributed its full share of men and means. In the war of 1812-1814 Vermont is credited with 5236 soldiers in regular service, exclusive of

2500 volunteers who were under arms at Plattsburg in September, 1814. In the Civil War of 1861-1865 the State furnished more than its due quota of troops, 33,288 men from a total population (1860) of 315,098. The present organized force consists of but one regiment, with one battery, 565 men. The unorganized militia numbered 64,162 men in 1880.

The early history of the State may be found in Hiland Hall's and Thompson's *Histories*. Important documents are given in *Vermont State Papers* and in *Collections* of the Vermont Historical Society. Its part in the war of 1861-1865 is told in Benedict's *Vermont in the Civil War*. (J. E. G.)

VERNET, the name of three eminent French painters.

I. Claude Joseph Vernet (1714[1]–1789), who was born at Avignon on 14th August, 1714, when only fourteen years of age aided his father, a skilful decorative painter, in the most important parts of his work. But the panels of sedan chairs could not satisfy his ambition and he started for Rome. The sight of the sea at Marseilles and his voyage thence to Civita Vecchia made a deep impression on him, and immediately after his arrival he entered the studio of a marine painter, Bernardino Fergioni. Slowly but surely Claude Joseph made his way and attracted notice. With a certain conventionality in design, proper to his day, he allied the results of constant and honest observation of natural effects of atmosphere, which he rendered with unusual pictorial art. Perhaps no painter of landscapes or sea-pieces has ever made the human figure so completely a part of the scene depicted or so important a factor in his design. "Others may know better," he said, with just pride, "how to paint the sky, the earth, the ocean; no one knows better than I how to paint a picture." For twenty years Vernet lived on in Rome, producing views of seaports, storms, calms, moonlights, etc., when he was recalled (1753) to Paris, and executed, by royal command, the remarkable series of the seaports of France (Louvre) by which he is best known. On his return he became a member of the academy, but he had previously contributed to the exhibitions of 1746 and following years, and he continued to exhibit, with rare exceptions, down to the date of his death, which took place in his lodgings in the Louvre on 3d December, 1789. Amongst the very numerous engravers of his works may be specially cited Le Bas, Cochin, Basan, Duret, Flipart, and Le Veau in France, and in England Vivares.

II. Antoine Charles Horace Vernet (1758–1835), commonly called Carle, the youngest child of the above named, was born at Bordeaux in 1758, where his father was painting the view from the château of La Trompette (Louvre). He showed, at the age of five, an extraordinary passion for drawing horses, but went through the regular academical course as a pupil of Lépicié. Strangely enough, on arriving in Italy after carrying off the great prize (1782), he lost all ambition and interest in his profession, so that his father had to recall him to France to prevent his entering a monastery. In Paris Carle Vernet became himself again and distinguished himself at the exhibition of 1791 by his Triumph of Paulus Æmilius, a work in which he broke with reigning traditions in classical subjects and drew the horse with the forms he had learned from nature in stables and riding-schools. But the Revolution drew on and Carle Vernet's career for awhile seemed to end in the anguish of his sister's death on the scaffold. When he again began to produce, it was as the man of another era: his drawings of the Italian campaign brought him fresh laurels; his vast canvas, the Battle of Marengo, obtained great success; and for his Morning of Austerlitz Napoleon bestowed on him the Legion of Honor. His hunting-pieces, races, landscapes, and work as a lithographer (chiefly under the restoration) had also a great vogue. From Louis XVIII. he received the order of St. Michael. In 1827 he accompanied his son Horace (see below) to Rome, and died in Paris on his return, 17th November, 1835, having produced but little during the last years of his life.

III. Émile Jean Horace Vernet (1789–1863), born in Paris, 30th June, 1789, was one of the most characteristic, if not one of the ablest, of the military painters of France. He was just twenty when he exhibited the Taking of an Entrenched Camp—a work which showed no depth of observation, but was distinguished by a good deal of character. His picture of his own studio (the rendezvous of the Liberals under the Restoration), in which he represented himself painting tranquilly, whilst boxing, fencing, drum and horn playing, etc., were going on, in the midst of a medley of visitors, horses, dogs, and models, is one of his best works, and together with his Defence of the Barrier at Clichy (Louvre), won for him an immense popularity. Enjoying equal favor with the court and with the opposition, he was most improperly appointed director of the school of France at Rome, from 1828 to 1835, and thither he carried the atmosphere of racket in which he habitually lived.[2] After his return the whole of the Constantine room at Versailles was decorated by him in the short space of three years. This vast work shows Vernet at his best and at his worth: as a picture it begins and ends nowhere and the composition is all to pieces; but it has good qualities of faithful and exact representation. He died at Paris on 17th January, 1863. The twenty works which were exhibited after his death confirmed his reputation for extraordinary facility; he had tried every sort of subject, showing affinity for all that was anecdotic rather than dramatic, failing most wherever most was demanded of him, and never reaching either beauty of color or dignity of line. Vernet was in short a brilliant offhand sketcher of all he saw, as he said himself, "from his window," and even in this work there was a good deal of affectation of the impromptu.

See Lagrange, *Joseph Vernet et la Peinture au XVIII. Siècle;* C. Blanc, *Hist. de l'École Française*, and T. Sylvestre, *Peintres Contemporains.*

VERNIER, Pierre (*c.* 1580–1637), inventor of the instrument which bears his name, was born at Ornans (near Besançon) in Burgundy about 1580. He was for a considerable time commandant of the castle in his native town. In 1631 he published at Brussels a treatise entitled *Construction, usage, et propriétés, du quadrant nouveau de mathématiques*, in which the instrument associated with his name is described (see Navigation, vol. xvii. p. 262, and Surveying, vol. xxii. p. 754). He died at Ornans in 1637.

The instrument invented by Vernier is frequently called a nonius; but this is incorrect, as the contrivance described by Pedro Nuñez in his work *De crepusculis* (1542) is a different one. Nuñez drew on the plane of a quadrant 44 concentric arcs divided respectively into 89,88, . . . 46 equal parts; and, if the alidade did not coincide with one of the divisions on the principal arc, it would fall more or less accurately on a division line of one of the auxiliary arcs, from which the value of the measured angle could be made out. This instrument was, however, very difficult to make, and was but little used. Vernier proposed to attach to a quadrant divided into half degrees a movable sector of a length equal to 31 half degrees, but divided into 30 equal parts, whereby single minutes could be read off by seeing which division line of the "sector" coincided with a division line of the quadrant. This movable arc was in other words divided into $\frac{n+1}{n}$ parts, and the divisions were graduated in the direction opposite to that of the graduation of the principal arc, it is now usual to divide it into $\frac{n-1}{n}$ parts, the two graduations going in the same direction. The idea had been mentioned by Christopher Clavius (1537-1612) in his *Opera mathematica*, 1612 (vol. ii. p. 5 and iii. p. 10), but he did not propose to attach permanently an arc divided in this way to the alidade; this happy application of the principle at all events belongs to Vernier.

VERNON, EDWARD (1684–1757), English admiral, was born in Westminster, on 12th November, 1684, and is said to have been descended from the ancient family of Vernon, long resident at Hanbury in Staffordshire. His father, James Vernon, secretary of state from 1697 to 1700, is best remembered by three volumes of his letters to the Duke of Shrewsbury, which were published in 1841; and his mother was Mary, daughter of Sir John Buck of Lincolnshire. Edward, their second son, was sent to Westminster school, but his heart longed for the roving life of the sea, and his stay in that "seed-plot of learning" was but brief. Outside its walls he studied, with a view to his future profession, such branches of knowledge as geometry, geography, and the construction of military weapons. He entered the navy in 1701 and from that time until 1707 took part in many expeditions in the Mediterranean and the West Indies. He served with Sir George Rooke at the taking of Gibraltar in July, 1704; and on his return to England Queen Anne acknowledged his gallantry with the present of two hundred guineas. He next went to the West Indies as rear-admiral to Sir Charles Wager, a brave seaman, who afterwards rose to the highest position at the admiralty in the Whig ministry of Walpole, and was pitted against Vernon both in the House of Commons and at the polling-booth. In 1715, and again in 1726, Vernon assisted in the naval operations in the Baltic, supporting Sir John Norris in the first enterprise, and on the latter serving under his old chief, Sir Charles Wager. During the long supremacy of Walpole little opportunity arose for distinction in warfare, and Vernon's energies found relief in politics. At the general election of 1722 he was returned for both Dunwich in Suffolk and Penryn in Cornwall, but chose the latter constituency. In the succeeding parliament of 1727 he was again chosen member for Penryn; but he failed to retain his seat after the dissolution in 1734. At this period the English people regarded the Spaniards as their legitimate enemies, and the ill-feeling of the two countries was fanned both in poetry and in prose. The political antagonists of Walpole charged him with pusillanimity to Spain. With Pulteney and most of his associates this battle-ground was selected rather from expediency than from principle; but Vernon represented the natural instincts of the sea-captain, and with the sailor as with the soldier the motto was "No peace with Spain." In debate he spoke often, and frequently with effect, but his language always savored of extravagance. He pledged himself in 1739 to capture Porto Bello with a squadron of but six ships, and the minister whom he had assailed with his invectives sent him, as vice-admiral of the blue and commander of the fleet in the West Indies, to the enterprise with the force which he had himself called sufficient. Vernon weighed anchor from Spithead on 23d July, 1739, and arrived off Porto Bello on 20th November. Next day the combat began with a bombardment of an outlying fort which protected the mouth of the harbor, and on 22d November the castle and town surrendered with a loss on the English side of only seven men. The joy of the nation knew no bounds. Vernon's birthday was celebrated in 1740 in London with public illuminations, and 130 medals were struck in his honor. In February, 1741, in a bye-election at Portsmouth Vernon was again sent to parliament. At the general election in the following May he was returned for Ipswich, Rochester, and Penryn, and all but succeeded in winning Westminster.[1] A larger squadron was placed under Vernon's command at the close of 1740, and with this force he resolved upon attacking Cartagena. After a fierce struggle the castle, which stood at the harbor's entrance, was gained; but in the attack upon the city the troops and sailors failed to act in concert, and, with the numbers of his forces thinned by combat and by disease, the British admiral retired to Jamaica. The incidents of this disastrous attempt are described in Smollett's *Roderick Random*, chap. xxxi., etc. A similar enterprise in July, 1741, against Santiago in Cuba met with a similar reverse, and Vernon attributed the defeat to the divided command of the British forces. He landed at Bristol, 6th January, 1743, and on 24th January received the freedom of the city of London. When the country dreaded the march of Prince Charles to London, the fleet in the Downs was placed under the command of Vernon; but his jealous disposition brooked no interference from the admiralty, and on 1st January, 1746, he struck his flag and handed over the command to another. His next act was to describe his grievances in a couple of angry pamphlets, revealing the communications of his official chiefs, and for this indiscretion he was struck off the list of flag officers (11th April, 1746). He continued to represent the borough of Ipswich until his death, but with this proceeding his public services practically ceased. He died suddenly at Nacton in Suffolk, 30th October, 1757, and was buried in the church of the village.

Vernon's gallantry was unquestioned; but his valor not infrequently degenerated into foolhardiness, and he dwelt more often than is usual with British seamen on the merits of his own exploits. His politics were those of the Tory party, and his differences with the Whigs and with his colleagues in the services led to his publishing several pamphlets on his political conduct. *A Memorial of Admiral Vernon from Contemporary Authorities* was printed by W. F. Vernon for private circulation in 1861.

VERONA, an important city of northern Italy, in the province of Venetia, situated (45° 26′ 8″ N. lat. and 10° 59′ 4″ E. long.) in a loop made by the winding of the Adige (ancient *Athesis*). It lies at the junction of the Adige valley railway and that from Mantua with the Milan, Vicenza, and Venice line, 25 miles north of Mantua and 30 south-southwest of Vicenza.

Church of S. Zeno.

Modern City.—The basilica of S. Zeno (an early bishop of Verona who became its patron saint), which stands outside the ancient city, is one of the most interesting churches in Italy, but has been recently much injured by "restoration." The church was remodelled in the 12th century, to which period most of the existing structure belongs, including the richly sculptured west front and the open "confessio" or crypt, which occupies the eastern half of the church, raising the choir high above the nave,—a plan adopted in S. Miniato near Florence, the cathedral of Parma, at Coire in Switzerland, and elsewhere. This arrangement was probably introduced by the northern invaders of Lombardy. The cloisters of S. Zeno, rebuilt in 1123, are an interesting example of brick and marble construction. Like many other churches in Verona, S. Zeno is mainly built of mixed brick and stone in alternate bands: four or five courses of fine red brick lie between bands of hard, cream-colored limestone or marble,[2] forming broad stripes of red and white all over the wall. A similarly variegated effect in red and white is produced by building the arches of windows and doors with alternating voussoirs in brick and marble.[3]

Cathedral.

The cathedral, consecrated in 1187, by Pope Urban III., stands at the northern extremity of the ancient city, by the bank of the Adige; it is inferior in size and importance to S. Zeno, but has a fine 12th-century west front of equal interest, richly decorated with Lombardic sculpture. The rest of the exterior is built in bands of red and white, with slightly projecting pilasters along the walls; it has a noble cloister, with two stories of arcading. Its baptistery, rebuilt early in the 12th century, is a quite separate building, with nave and apse, forming a church dedicated to S. Giovanni in Fonte. Pope Lucius III., who held a council at Verona in 1184, is buried in the cathedral, under the pavement before the high altar.

---

[1] Grego's *Parliamentary Elections*, London, 1886, pp. 95–106.

[2] The neighborhood of Verona is especially rich in fine limestones and marbles of many different kinds, especially a close-grained cream-colored marble and a rich mottled red marble, which are largely used, not only in Verona, but also in Venice and other cities of the province. The same quarry produces both kinds, and indeed the same block is sometimes half red and half white.

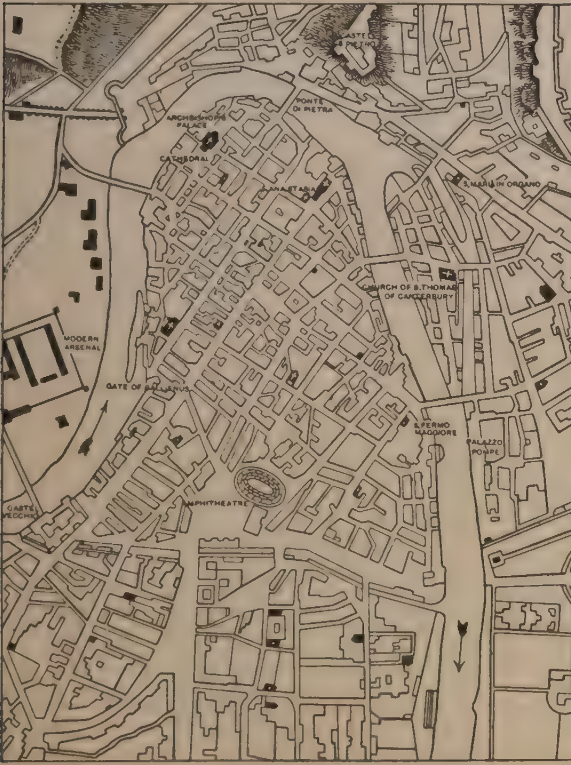
Church of S. Anastasia.

Church of S. Fermo.

Other churches.

The Dominican church of S. Anastasia is a mine of wealth in early examples of painting and sculpture, and one of the finest buildings in Italy of semi-Gothic style. It consists of a nave in six bays, aisles, transepts, each with two eastern chapels, and an apse, all vaulted with simple quadripartite brick groining.[1] It dates from the latter part of the 13th century and is specially remarkable for its very beautiful and complete scheme of color decoration, much of which is contemporary with the building. The vaults are very gracefully painted with floreated bands along the ribs and central patterns in each "cell," in rich soft colors on a white plastered ground. The eastern portion of the vaulting, including the choir and one bay of the nave, has the older and simpler decorations; the rest of the nave has more elaborate painted ornament,—foliage mixed with figures of Dominican saints, executed in the 15th century. On the walls below are many fine frescos, ranging from *c.* 1300 to the 15th century, including Pisanello's beautiful painting of St. George (mentioned below). This church also contains a large number of fine sculptured tombs of the 14th and 15th centuries, with noble effigies and reliefs of saints and sacred subjects. It is mainly built of red brick, with fine nave columns of red and white marble and an elaborate marble pavement inlaid in many different patterns. Its general proportions are specially noble. The church of S. Fermo Maggiore comes next in interest. With the exception of the crypt, which is older, the existing edifice was rebuilt in the 14th century. Its plan is very unusual, consisting of a large nave without aisles, the span being between 45 and 50 feet; it also has two shallow transepts and an apsidal east end. The roof, which is especially magnificent, is the finest example of a class which as a rule is only found in Venetia:[2] the framing is concealed by coving or barrel-vaulting in wood, the surface of which is divided into small square panels, all painted and gilt, giving a very rich effect. In this case the 14th and 15th century painted decorations are well preserved. Delicate patterns cover all the framework of the panelling and fill the panels themselves; at two stages, where there is a check in the line of the covering, rows of half-figures of saints are minutely painted on blue or gold grounds, forming a scheme of indescribably splendid decoration. A simpler roof of the same class exists at S. Zeno; it is trefoil-shaped in section, with a tie-beam joining the cusps. The church of S. Maria in Organo, rebuilt by Sanmichele, contains paintings by various Veronese masters. Though not built till after his death, the church of S. Giorgio in Braida, on the other side of the river, was also designed by Sanmichele, and possesses many good pictures of the Veronese school. There are several other fine churches in Verona, some of early date. One of the 14th century is dedicated to Thomas a Becket of Canterbury.



Plan of Verona.

Bridges and castles.

The strongly fortified castle built by the Della Scala lords in the 14th century stands on the line of the Roman wall, close by the river. A very picturesque battlemented bridge leads from it to the other shore, sloping down over three arches of different sizes, the largest next to the castle and the smallest at the other end. There are four other bridges across the Adige; one, the graceful Ponte di Pietra, was designed by Fra Giocondo. The 16th-century lines of fortification enclose a very much larger area than the Roman city, forming a great loop to the west, and also including a considerable space on the left bank of the river. In the latter part of the city, on a steep elevation, stands the castle of St. Peter, originally founded by Theodoric, mostly rebuilt by Gian Galeazzo Visconti in 1393, and dismantled by the French in 1801. This and the other fortifications of Verona were rebuilt or repaired by the Austrians, but are no longer kept up as military defences. Verona, which is the chief military centre of the Italian province of Venetia, is now being surrounded with a circle of forts far outside the obsolete city walls.

Palaces.

The early palaces of Verona, before its conquest by Venice, were of very noble and simple design, mostly built of fine red brick, with an inner court, surrounded on the ground floor by open arches like a cloister, as, for example, the Palazzo della Ragione, an assize court, begun in the 12th century. The arches, round or more often pointed in form, were decorated with moulded terra-cotta enrichments, and often with alternating voussoirs of marble. The Scaligeri Palace is a fine example, dating from the 14th century, with, in the cortile, an external staircase leading to an upper loggia, above the usual arcade on the ground floor. It has a very lofty campanile, surmounted by a graceful octagonal upper story. This palace is said to have been mainly built by Can Signorio (Della Scala) about 1370. After the conquest by Venice the domestic buildings of Verona assumed quite a different type. They became feeble copies of Venetian palaces, in which one form of window, with an ogee arch, framed by the dentil moulding is almost always used. The monotony and utter lifelessness of this form of architecture are shown in the meaningless way in which details, suited only to the Venetian methods of veneering walls with thin marble slabs, are copied in the solid marbles of Verona. From the skill of Fra Giocondo (see below), Verona was for many years one of the chief centres in which the most refined and graceful forms of the early Renaissance were developed. The town-hall, with its light open loggia of semicircular arches on the ground floor, was designed by Fra Giocondo towards the end of the 15th century; its sculptured enrichments of pilasters and friezes are very graceful, though lacking the vigorous life of the earlier mediæval sculptured ornamentation. Verona contains a number of handsome, though somewhat uninteresting, palaces designed by Sanmichele in the 16th century. The finest are those of the Bevilacqua,[1] Canossa, and Pompei families. The last of these is now the property of the city, and contains a gallery with some good pictures, especially of the Verona, Padua, and Venice schools. As in Venice, many of the 16th-century palaces in Verona had stuccoed façades, richly decorated with large fresco paintings, often by very able painters. One of these, the house of the painter Niccolo Giolfino, still has its frescos in a good state of preservation, and gives a vivid notion of what must once have been the effect of these gorgeous pictured palaces. The episcopal palace contains the ancient and valuable chapter library, of about 12,000 volumes and over 1000 MSS., among them the palimpsest of the *Institutiones* of Gaius which Niebuhr discovered. The Piazza delle Erbe (fruit market) and the Piazza dei Signori, both in the oldest part of the city, are very picturesque and beautiful, being surrounded by many fine mediæval buildings. In the former of these a copy of the lion of Venice has recently been erected.

---

[1] This type of church was specially adopted by the Dominicans in Italy.

[2] Or in churches built by Venetian architects in Istria and other subject provinces.

Squares.

Population, industry, etc.

Verona had a population of 67,080 in 1871, which by 1881 had increased to 68,741. In spite of its pleasant and healthy site, Verona is in winter liable to be cold and rainy, like other places which lie along the southern spurs of the Alps. The Adige, a rapid but shallow river, shrinks to an insignificant stream during the summer. Verona possesses some silk, linen, and woollen manufactures, and carries on a considerable trade in these goods and in grain, hides, flax, hemp, marbles, drugs, etc. Amongst the public institutions of the place may be mentioned the public library (1802), the agricultural academy (1768), the botanical garden, various good schools and colleges (including a theological seminary, a lyceum, and gymnasia), and numerous hospitals and charitable organizations.

Roman remains.

Roman Remains.—The most conspicuous of the existing Roman remains is the great amphitheatre, a building of the 2d or 3d century, which in general form closely resembled the Colosseum in Rome. Almost the whole of its external arcades, with three tiers of arches, have now disappeared; it was partly thrown down by an earthquake in 1184, and subsequently used as a stone-quarry to supply building materials. Many of its blocks are still visible in the walls of various mediæval buildings. The interior, with seats for about 20,000 people, has been frequently restored, till none of the old seats remain. Traces also exist of extensive baths and of a Roman theatre, the latter outside the most ancient line of walls, close to the left bank of the river. In 1885 portions of a number of fine mosaic pavements, dating from the 3d century, were discovered extending over a very large area under the cloister and other parts of the cathedral, about 5 feet below the present floor level. A large number of different patterns exist in a good state of preservation, elaborate in style, but, like all late Roman mosaics, rather coarsely executed with large *tesseræ*. The Museo Lapidario contains a fine collection of Roman and Etruscan inscriptions and sculpture, mostly collected and published by Scipione Maffei in the 18th century.

Artistic Importance.—In many respects the resemblance between Verona and Florence is very striking: in both cases we have a strongly fortified city built in a fertile valley, on the banks of a winding river, with suburbs on higher ground, rising close above the main city. In architectural magnificence and in wealth of sculpture and painting Verona almost rivalled the Tuscan city, and, like it, gave birth to a very large number of artists who distinguished themselves in all branches of the fine arts.

Painting.

Painting in Verona may be divided into four periods. (i.) The first period is characterized by wall paintings of purely native style, closely resembling the early Christian pictures in the catacombs of Rome. Examples dating from the 10th to the 11th century have been discovered hidden by whitewash on the oldest parts of the nave walls of the church of S. Zeno. They are a very interesting survival of the almost classical Roman style of painting, and appear to be quite free from the generally prevalent Byzantine influence. (ii.) The Byzantine period seems to have lasted during the 12th and 13th centuries. (iii.) The Giottesque period begins contemporaneously with Altichiero da Zevio and Giacomo degli Avanzi, whose chief works were executed during the second half of the 14th century. These two painters were among the ablest of Giotto's followers, and adorned Verona and Padua with a number of very beautiful frescos, rich in composition, delicate in color, and remarkable for their highly finished modelling and detail. (iv.) To the fourth period belong several important painters. Pisanello or Vittore PISANO (*q.v.*), a very charming painter and the greatest medallist of Italy, was probably a pupil of Altichiero.[2] Most of his frescos in Verona have perished; but one of great beauty still exists in a very perfect state in the church of S. Anastasia, high up over the arched opening into one of the eastern chapels of the south transept. The scene represents St. George and the Princess after the Conquest of the Dragon, with accessory figures, the sea, a mountainous landscape, and an elaborately painted city in the background. The only other existing fresco by Pisanello is an Annunciation in S. Fermo Maggiore. For Pisanello's pupils and other painters of subsequent date, see SCHOOLS OF PAINTING, vol. xxi. p. 451. Domenico del Riccio, usually nicknamed Brusasorci (1494–1567), was a prolific painter whose works are very numerous in Verona. Paolo Cagliari or Paul VERONESE (*q.v.*), though a native of Verona, belongs rather to the Venetian school.

Sculpture.

Verona is specially rich in early examples of decorative sculpture. (i.) The first period is that of northern or Lombardic influence, exemplified in the very interesting series of reliefs which cover the western façades of the church of S. Zeno and the cathedral, dating from the 12th century. These reliefs represent both sacred subjects and scenes of war and hunting, mixed with grotesque monsters, such as specially delighted the rude vigorous nature of the Lombards; they are all richly decorative in effect, though strange and unskilful in detail. Part of the western bronze doors[3] of S. Zeno are especially interesting as being among the earliest important examples in Italy of cast bronze reliefs. They represent scenes from the life of S. Zeno, are rudely modelled, and yet very dramatic and sculpturesque in style.[4] Many of the 12th-century reliefs and sculptured capitals in S. Zeno are signed by the sculptor, but these merely constitute lists of names about whom nothing is known. (ii.) In the 13th century the sculpture seems to have lost the Lombard vigor, without acquiring any qualities of superior grace or refinement. The font in the baptistery near the cathedral is an early example of this. Each side of the octagon is covered with a large relief of a Biblical subject, very dull in style and coarse in execution. The font itself is interesting for its early form, one common in the chief baptisteries of northern Italy; like an island in the centre of the great octagonal tank is a lobed marble receptacle, in which the officiating priest stood while he immersed the catechumens. A movable wooden bridge must have been used to enable the priest to cross the water in the surrounding tank. (iii.) The next period is that of Florentine influence. This is exemplified in the magnificently sculptured tombs of the Della Scala lords, designed with steadily growing splendor, from the simple sarcophagus of Martino I. down to the elaborate erection over the tomb of the fratricide Can Signorio, adorned with statuettes of the virtues, to the possession of which he could lay so little claim.[5] The recumbent effigies and decorative details of these tombs are very beautiful, but the smaller figures of angels, saints, and virtues are rather clumsy in proportion. The latest tomb, that of Can Signorio, erected during his lifetime (*c.* 1370), is signed "Boninus de Campigliono Mediolanensis Dioscesis." This sculptor, though of Milanese origin, belongs really to the school of the Florentine Andrea Pisano. One characteristic of the 14th and 15th centuries in Verona was the custom, also followed in other Lombardic cities, of setting large equestrian statues over the tombs of powerful military leaders, in some cases above the recumbent effigy of the dead man, as if to represent him in full vigor of life as well as in death. That which crowns the canopy over the tomb of Can Grande is a very noble, though somewhat quaint, work. (iv.) In the 15th century the influence of Venice became paramount, though this was really only a further development of the Florentine manner, Venice itself having been directly influenced in the 14th century by many able sculptors from Florence.

---

[1] The valuable collection of works of art once preserved in the Bevilacqua Palace has long since been dispersed.

[2] There is every reason to doubt Vasari's statement that Pisanello was a pupil of Andrea del Castagno.

[3] They are frequently stated to be of beaten bronze, but they are really castings, apparently by the *cire perdue* process.

[4] Part of these doors are covered with bronze reliefs of scenes from the Bible, which are of still earlier date, and were probably brought to Verona from the Rhine provinces.

[5] See an eloquent description by Ruskin, *Stones of Venice*, iii. p. 70 *sq.*

Architecture.

The architecture of Verona, like its sculpture, passed through Lombard, Florentine, and Venetian stages. (i.) The church of S. Zeno and the cathedral, both of which were mainly rebuilt in the 12th century, are very noble examples of the Lombardic style, with few single-light windows, and with the walls decorated externally by series of pilasters and by alternating bands of red and white, in stone or brick. The arches of this period are semicircular and rest on round columns and capitals, richly carved with grotesque figures and foliage. Most of the external ornamentation is usually concentrated on the western front, which often has a lofty arched porch on marble columns, resting on griffins or lions devouring their prey. (ii.) The Florentine period (*c.* 1250 to 1400) is represented by the church of S. Anastasia, and by many more or less mutilated palaces, with fine courts surrounded by arcades in one or more stories. The arches are mostly pointed, and in other respects the influence of northern Gothic was more direct in Verona than in Florence. Solidity of mass and simplicity of detail are among the characteristics of this period. (iii.) The Venetian period (*c.* 1400 to 1480) was one of little originality or vigor, the buildings of this date being largely rather dull copies of those at Venice. (iv.) The early Renaissance developed into very exceptional beauty in Verona, mainly through the genius of Fra Giocondo (1435–1514), a native of Verona, who was at first a friar in the monastry of S. Maria in Organo. He rose to great celebrity as an architect, and designed many graceful and richly sculptured buildings in Venice, Rome, and even in France; he used classical forms with great taste and skill, and with much of the freedom of the older mediæval architects, and was specially remarkable for his rich and delicate sculptured decorations. The Roman gateway of Gallienus (mentioned below) supplied a special form of window, with a circular arch on pilasters, surmounted by a cornice; this was copied by Fra Giocondo, and has been used by countless architects down to the present day without any alteration whatever,[1] —a remarkable history for a design: it was invented in the 3d century, revived in the 15th, and again copied in the 19th. Another of the leading architects of the next stage of the Renaissance was the Veronese Michele SANMICHELE (*q.v.*), a great military engineer, and designer of an immense number of magnificent palaces in Verona and other cities of Venetia. His buildings are stately and graceful in proportion, but show a tendency towards that dull scholastic classicism which in the hands of Palladio put an end to all real life in the art.

History.

History.—Nothing is certainly known of the history of Verona until it became a Roman colony with the title of *Augusta*, together with the rest of Venetia (Tac., *Hist.*, iii. 8, and Strabo, p. 213). Its fertile surroundings, its central position at the junction of several great roads, and the natural strength of its position, defended by a river along two-thirds of its circumference, all combined to make Verona one of the richest and most important cities in northern Italy, although its extent within the walls was not large. The existing remains of wall and gates are shown by inscriptions on them to date from the 3d century; the ancient *fossa* still exists as an open canal, so that the old part of the city is wholly surrounded by water. One very handsome gateway inside the Roman city, now called the Porta de' Borsari, was restored in 265 by Gallienus. There are, however, traces of a more ancient circuit wall and gates on the old line. The emperor Constantine, while advancing towards Rome from Gaul, besieged and took Verona (312); it was here, too, that Odoacer was defeated (489) by Theodoric the Goth, who built a palace at Verona and frequently resided there. Verona was the birthplace of Catullus.

In the Middle Ages Verona gradually grew in size and importance. In early times it was one of the chief residences of the Lombard kings;[2] and, though, like other cities of northern Italy, it suffered much during the Guelf and Ghibelline struggles, it rose to a foremost position both from the political and the artistic point of view under its rulers of the Scaliger or Della Scala family. The first prominent member of the family and founder of his dynasty was Martino I., who ruled over the city from 1260 till his death in 1277. Verona had previously fallen under the power of a less able despot, Ezzelino da Romano, who died in 1259. Alberto della Scala (died in 1301) was succeeded by his eldest son Bartolomeo, who was confirmed as ruler of Verona by the popular vote, and died in 1304. Alboino, the second son, succeeded his brother, and died in 1311, when the youngest son of Alberto, Can Grande, who since 1308 had been joint-lord of Verona with his brother, succeeded to the undivided power. Can Grande (Francesco della Scala, died in 1329) was the best and most illustrious of his line, and is specially famous as the hospitable patron of DANTE (*q.v.*). Other princes of this dynasty, which lasted for rather more than a century, were Giovanni (d. 1350), Martino II. (d. 1351), Can Grande II. (d. 1359), and Can Signorio (d. 1375). In 1389 Gian Galeazzo Visconti, duke of Milan, became by conquest lord of Verona. Soon after his death the city fell by treacherous means into the hands of Francesco II. di Carrara, lord of Padua. In 1404–5, Verona, together with Padua, was finally conquered by Venice, and remained subject to the Venetians till the overthrow of the republic by Napoleon in 1797, who in the same year, after the treaty of Campo Formio, ceded it to the Austrians with the rest of Venetia; and since that time its political history has been linked to that of Venice.

See the various works by Scipione Maffei (*Verona Illustrata*, 1728; *Museum Veronense*, 1749; and *La Antica Condizion di Verona*, 1719): also Panvinius, *Antiquitates Veronæ*, Padua, 1668; Da Pertico, *Descrizione di Verona*, 1820; and for some of the older buildings Street, *Brick and Marble Architecture*, London, 1855.

(J. H. M.)

VERONESE, PAOLO (1528–1588), the name ordinarily given to PAOLO CALIARI, or CAGLIARI, the latest of the great cycle of painters of the Venetian school, was born in Verona in 1528 according to the best authorities (Zanetti and others), or in 1532 according to Ridolfi. His father, Gabriele Caliari, a sculptor, began to train Paolo to his own profession. The boy, however, showed more propensity to painting, and was therefore transferred to his uncle, the painter Antonio Badile. According to Vasari, he was the pupil of Giovanni Carotto, a painter proficient in architecture and perspective; this statement remains unconfirmed. Paolo, in his early years, applied himself to copying from the engravings of Albert Dürer and the drawings of Parmigiano; and, having in a singular degree the gifts of facility, retentiveness, and amenity, he made rapid progress. He did some work in Verona, but found there little outlet for his abilities, the field being pretty well occupied by Ligozzi, Brusasorci, Battista dal Moro, Paolo Farinato, Domenico Riccio, and other artists. Cardinal Ercole Gonzaga took him, when barely past twenty years of age, to Mantua, along with the three last-named painters, to execute in the cathedral a picture of the Temptation of St. Anthony; here Caliari was considered to excel his competitors. Returning to Verona, he found himself exposed to some envy and ill-will. Hence he formed an artistic partnership with Battista Zelotti, and they painted together in the territories of Vicenza and Treviso. Finally Paolo went on to Venice. In this city his first pictures were executed in 1555 in the sacristy and church of St. Sebastian, an uncle of his being prior of the monastery. The subjects on the vaulting are taken from the history of Esther; and these excited so much admiration that thenceforward Caliari, aged about twenty-eight, ranked almost on a par with Tintoretto, aged about forty-five, or with Titian in his eightieth year, and his life became a series of triumphs. Besides the Esther subjects, these buildings contain his pictures of the Baptism of Christ, the Martyrdom of St. Marcus and St. Marcellinus, the Martyrdom of St. Sebastian, etc. As regards this last-named work, there is a vague tradition that Caliari painted it at a time when he had taken refuge in the monastery, for some reason now unknown. He entered into a competition for painting the ceiling of the library of St. Mark, and not only obtained the commission, but executed it with so much power that his very rivals voted him the golden chain which had been tendered as an honorary distinction. At one time he returned to Verona and painted the Banquet in the House of Simon the Pharisee, with Jesus and Mary Magdalene, for the refectory of St. Mazzaro,—a picture now in Turin. In 1560, however, he was in Venice again, working partly in the St. Sebastian buildings and partly in the ducal palace. He visited Rome in 1563, in the suite of Girolamo Grimani, the Venetian ambassador, and acquired enhanced elevation of style by studying the works of Raphael and Michelangelo, and especially the antique. Returning to Venice, he was overwhelmed with commissions, almost transcending the resources even of his own marvellous assiduity, fertility, and promptitude,—qualities in which no painter perhaps has ever surpassed him. He was compelled to decline an invitation from Philip II. to go to Spain and assist in decorating the Escorial. One of his pictures of this period is the famous Venice, Queen of the Sea, in the ducal palace. He died in Venice on the 20th (or perhaps 19th) of April, 1588, and was buried in the church of St. Sebastian, a monument being set up to him there by his two sons, Gabriele and Carlo, and his brother, Benedetto, all of them painters.

---

[1] As, for example, in Sir Gilbert Scott's Government offices, Whitehall, and many other recent buildings in London.

[2] Verona is the "Bern" of early German legendary history, and of the poems which celebrate the achievements of Charlemagne.

Beyond his magnificent performances as a painter, the known incidents in the life of Paul Veronese are (as will be perceived from the above account) very few. That he was prosperous is certain, and that he was happy is an almost necessary inference from the character of his pictures, on which the joy of living is ineffaceably stamped. He was honored and loved, being kind, amiable, generous, and an excellent father. His person is well known from the portraits left by himself and others; he was a dark man, rather good-looking than otherwise, somewhat bald in early middle age, and with nothing to mark an exceptional energy or turn of character. In his works the first quality which strikes one is the palatial splendor—grand architecture, stately vistas, personages of easy and affable dignity in sumptuous costumes, the crowded assemblies, the luxury of environment, the air and light, the graceful and abundant poise of action and of limb, the rhythmic movement, the sweet and lordly variegation of tint. The pictorial inspiration is entirely that of the piercing and comprehensive eye and the magical hand—not of the mind; for Veronese yields none but negative results to the touchstone either of exalted and profound imagination or of searching and constructive common-sense. The human form and face are given with decorous comeliness, often with beauty. He constantly painted his figures and faces from the life, thus securing range and precision of character; but of individual apposite expression there is next to none, and of reasoned realistic contact with the professed subject matter—whether in general disposition, in costume and accessory, or in attitude and effort of mind—there is frequently no trace at all. In fact, Paolo Veronese is pre-eminently a painter working pictorially, and in no wise amenable to a literary or rationalizing standard: you can neither exhibit nor vindicate his scenic apparatus by any transcription into words. He enjoys a sight much as Ariosto enjoys a story, and displays it in form and color with a zest like that of Ariosto for language and verse. As we have already indicated, he was supreme in representing, without huddling or confusion, numerous figures in a luminous and diffused atmosphere, while in richness of draperies and transparency of shadows he surpassed all the other Venetians or Italians. In gifts of this kind Rubens alone could be pitted against him. In the moderation of art combined with its profusion he far excelled Rubens; for, dazzling as is the first impression of a great work by Veronese, there is in it, in reality, as much of soberness and serenity as of exuberance. By variety and apposition he produces a most brilliant effect of color; and yet his hues are seldom bright. He hoards his primary tints and his high lights, like a rich miser who knows how to play the genial host on occasion. A colossal spontaneity, to which a great result is only a small effort of faculty, is the chief and abiding impression derived from contemplating his works. He very rarely produced small pictures: the spacious was his element.

Of all Veronese's paintings the one which has obtained the greatest world-wide celebrity is the vast Marriage at Cana, now in the Louvre. It contains about a hundred and twenty figures or heads—those in the foreground being larger than life. Several of them are portraits. Among the personages specified (some of them probably without sufficient reason) are the Marquis del Vasto, Queen Eleanor of France, Francis I., Queen Mary of England, Sultan Soleyman I., Vittoria Colonna, Charles V., Tintoretto, Titian, the elder Bassano, Benedetto Caliari, and Paolo Veronese himself (the figure playing the viol). It is impossible to look at this picture without astonishment; it enlarges one's conception of what pictorial art means and can do. The only point of view from which it fails is that of the New Testament narrative; for there is no more relation between the Galilean wedding and Veronese's court-banquet than between a true portrait of Lazarus and a true portrait of Dives. This stupendous performance was executed for the refectory of the monastery of S. Giorgio Maggiore in Venice, the contract for it being signed in June, 1562, and the picture completed in September, 1563. Its price was 324 silver ducats (=£160, [$777.60]) along with the artist's living-expenses and a tun of wine. There are five other great banquet-pictures by Caliari, only inferior in scale and excellence to this of Cana. One of them is also in the Louvre, a Feast in the House of Simon the Pharisee, painted towards 1570–75 for the refectory of the Servites in Venice. A different version of the same theme is in the Brera Gallery of Milan. The Feast of Simon the Leper, 1570, was done for the refectory of the monks of St. Sebastian, and the Feast of Levi (St. Matthew), 1573, now in the Venetian academy, for the refectory of the monks of St. John and St. Paul. In each instance the price barely exceeded the cost of the materials, so different were the conditions under which an artist even of the first celebrity, as Veronese then was, worked in Italy in the 16th century from the conditions prevailing at the present day. The Louvre contains ten other specimens of Veronese, notably the Susanna and the Elders, and the Supper at Emmaus. In the London National Gallery are six examples. The most beautiful is St. Helena's Vision of the Cross, founded upon an engraving by Marcantonio after a drawing supposed to be the work of Raphael. Far more famous than this is the Family of Darius at the Feet of Alexander the Great after the Battle of Issus—the captives having mistaken Hephæstion for Alexander. It was bought for £13,560, [$65,935.62] and has even been termed (very unreasonably) the most celebrated of all Veronese's works. The principal figures are portraits of the Pisani family. It is said that Caliari was accidentally detained at the Pisani villa at Este, and there painted this work, and, on quitting, told the family that he had left behind him an equivalent for his courteous entertainment. Another picture in the National Gallery, Europa and the Bull, is a study for the large painting in the imperial gallery of Vienna, and resembles one in the ducal palace of Venice. The Venetian academy contains fourteen works by Veronese. One of the finest—it is indeed a singular and choice masterpiece—is a comparatively small picture of the Battle of Lepanto, with Christ in heaven pouring light upon the Christian fleet and darkness on the Turkish. In the Uffizi Gallery of Florence are two specimens of exceptional beauty—the Annunciation and Esther Presenting herself to Ahasuerus; for delicacy and charm this latter work yields to nothing that the master produced. In Verona St. George and St. Julian, in Brescia the Martyrdom of St. Afra, and in Padua the Martyrdom of St. Justina are works of leading renown. The drawings of Veronese are very fine, and he took pleasure at times in engraving on copper.

The brother and sons of Paolo already mentioned, and Battista Zelotti, were his principal assistants and followers. Benedetto Caliari, the brother, who was about ten years younger than Paolo, is reputed to have had a very large share in designing and executing the architectural backgrounds which form so conspicuous a feature in Paolo's compositions. If this is not overstated, it must be allowed that a substantial share in Paolo's fame accrues to Benedetto; for not only are the backgrounds admirably schemed and limned, but they govern to a large extent the invention and distribution of the groups. Of the two sons Carlo (or Carletto), the younger, is the better known. He was born in 1570, and was the favorite of his father, who sent him to study under Bassano. He produced various noticeable works, and died young in 1596. Gabriele, born in 1568, attended, after Carlo's death, almost entirely to commercial affairs; his works in painting are rare. All three were occupied after the death of Paolo in finishing his pictures left uncompleted.

(W. M. R.)

VERONICA, St. According to the Bollandists (4th Feb.), Veronica or Berenice was a pious woman of Jerusalem who, moved with pity as Jesus bore His cross to Golgotha, gave Him her kerchief that He might wipe the drops of agony from His brow. The Lord accepted the offering and after using it handed it back to her, bearing the image of His face miraculously impressed upon it. According to various forms of the legend, Veronica is identified with the niece of Herod the Great, with the woman whom Christ healed of an issue of blood (Mark v. 25 *sq.*; Matt. ix. 20 *sq.*), with a woman who afterwards, along with fifty others, young men and maidens, suffered martyrdom at Antioch, and with the beloved of one Amator, who is described as "famulus S. Virginis Mariæ et Josephi, et Domini bajulus ac nutricius," who afterwards became an ascetic and died at Roquemadore (Rupes Amatoris) near Bordeaux. Current tradition in the Roman Church has it that Veronica was able to heal Tiberius of a grievous sickness with her napkin, and that the emperor, thus convinced of the divinity of Christ, forthwith sent Pilate into exile. This napkin (*sudarium*) was in the time of Pope John VII. (705) in the church of S. Maria Maggiore in Rome, but is now in St. Peter's, though possession of it is indeed claimed also by Milan and Jaen (Spain). The Bollandist form of the story cannot be traced further back than to about the second quarter of the 15th century; but in a MS. of the 8th century, now in the Vatican, Veronica is said to have painted, or caused to be painted, the portrait of Christ after she had been healed by Him. In the 13th century we find the miraculous picture itself spoken of as "figura Domini quæ Veronica dicitur," and this has suggested to archæologists the question whether the legend of the woman Veronica may not have arisen by confusion out of a totally distinct legend as to a vera icon (εἰκών), such as that which, according to Greek tradition, Jesus sent with an autograph letter to Abgarus of Edessa. St. Veronica is commemorated on Shrove Tuesday, but her festival is not of obligation.[1]

See Karl Pearson's *Die Fronica, ein Beitrag zur Geschichte des Christusbildes in Mittelalter* (Strasburg, 1887), which contains a discussion of the evolution of the story and much interesting matter relating to the hymnological, liturgical, and artistic aspects of the subject.

VERRES (*c.* 112–43 B.C.), whose name has been branded with everlasting infamy by the speeches of Cicero, was the bad son of a bad father. The elder Verres was an old hand at jobbery and bribery, and some of his son's ill-gotten gains found their way into his pocket. He had some sort of connection with the dictator Sulla, and it was through this probably that he rose to be a senator; possibly, though this is very doubtful, he may have belonged to some branch of the Cornelian family, or have been adopted into it. The younger Verres held his first important appointment about 82 B.C. as quæstor of the consul Carbo in Cisalpine Gaul. This implies that he was then of the democratic party of Marius; but he left it the same year, after having deserted and betrayed Carbo and embezzled the public moneys of which as quæstor he had the handling. As a reward for his treachery he got out of Sulla a slice of the landed property of some of the proscribed citizens of Beneventum, and Sulla probably screened him in the following year when he was threatened with an action by the treasury officials for his peculations under Carbo. Next year, 80 B.C., he was in Asia on the staff of Dolabella, governor of Cilicia, where he again acted as quæstor. The governor and his subordinate plundered in concert, till in 78 B.C. Dolabella had to stand his trial at Rome, and was convicted, mainly on the evidence of Verres, who thus secured a pardon for himself. In 74 B.C. he was elected prætor, bribing heavily, it was said, and he had what was termed the city prætorship, which gave him all the powers of an English lord chancellor, with but inadequate checks on their abuse. Verres, as a creature of Sulla's, in several of his judicial decisions turned them to political ends for the advantage of himself and his party. After his year of prætorship Verres went as governor to Sicily, the richest and most attractive of the Roman provinces, with its treasures of Greek art, its Greek civilization, and its many noble and beautiful cities. Rome had recognized the claims of Sicily to a kindly and indulgent rule, and the people were for the most part comfortable and contented. But under Verres the island experienced more utter misery and desolation than it had felt amid the horrors of that long and fierce struggle, the First Punic War. The corn-growers, and the revenue-collectors or "publicans," were ruined by exorbitant imposts or by the iniquitous cancelling of contracts; temples and private houses were robbed of their works of art, which to the Sicilian Greek were even dearer than his money; and to all this were added insult and outrage. Men who had the Roman franchise, which was now beginning to be widely diffused, were among the victims of Verres: one was scourged publicly at Messana on an unproved charge. Verres returned to Rome in 70 B.C., with plunder which he boasted would enable him to live in ease and luxury, even if he had to surrender two-thirds of it to bribe a Roman jury. The prosecution which he anticipated was commenced the same year by the provincials of Sicily, and was at their request undertaken by Cicero. Verres entrusted his defence to the most eminent of Roman advocates, Hortensius, and he had the sympathy and support of several of the leading Roman nobles. The court before which he was to be tried was composed exclusively of senators, some of whom might be his personal friends. But the presiding judge, the city prætor, Acilius Glabrio, was a thoroughly honest man, and his assessors were at least not accessible to bribery. Cicero took care that the evidence should be overwhelming, and he had a host of witnesses in readiness, not only from the ill-used towns of Sicily, but from every part of the Greek world. The trial, one of the most memorable in antiquity, began early in the August of 70 B.C., after an unsuccessful attempt by the counsel for Verres to get it adjourned to the following year, when Hortensius would himself be consul, and the presiding judge, Metellus, one of his political friends. Cicero opened the case with a comparatively brief speech (*Actio Prima in Verrem*), following it up with the examination of witnesses and documentary evidence, and convincing Hortensius that his client's cause was hopeless. Before the expiration of the nine days allowed for the prosecution Verres was on his way to Marseilles; there he lived in exile to the year 43 B.C., with abundant means of enjoying life in his own way. The story went (Pliny, *N. H.*, xxxiv. 2) that his name was on the proscription list of Marcus Antonius, and that in fact he owed his death to the murderer of Cicero.

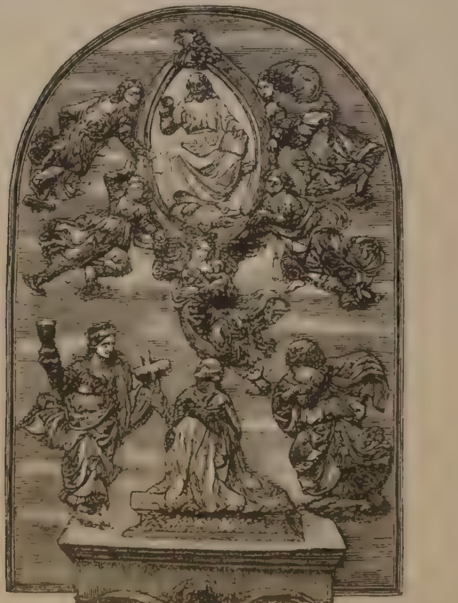
Verres may not have been quite so black as he is painted by Cicero, on whose speeches we depend entirely for our knowledge of the man, but there can hardly be a doubt that he stood pre-eminent among the worst specimens of Roman provincial governors. It is cruelly unjust to the memory of Warren Hastings to suggest a comparison between him and Verres, though between the two trials, between the charges made, and the general character and circumstances of the proceedings there are points of striking resemblance. But there is a clearly marked difference. Verres cared simply for himself; Hastings thought much of the greatness and glory of his country. For one thing indeed we have to thank Verres,—for the detailed description of Sicily and its Greek art treasures which we have in Cicero's famous Verrine orations.

VERROCCHIO, Andrea del (1435–1488), one of the most distinguished Florentine artists of the 15th century, equally famed as a goldsmith, sculptor, and painter, was born at Florence in 1435. He was the son of Michele di Francesco de' Cioni, and took his name from his master, the goldsmith Giuliano Verrocchi. Except through his works, little is known of his life. As a painter he occupies an important position from the fact that Leonardo da Vinci and Lorenzo di Credi worked for many years in his bottega as pupils and assistants. Only one existing painting can be attributed with absolute certainty to Verrochio's hand, the celebrated Baptism of Christ, originally painted for the monks of Vallombrosa, and now in the academy of Florence. The figures of Christ and the Baptist are executed with great vigor and refinement of touch, but are rather hard and angular in style. As Vasari says, Verrocchio "ebbe la maniera alquanto dura e crudetta." The two angels are of a much more graceful cast; the face of one is of especial beauty, and Vasari is probably right in saying that this head was painted by the young Leonardo. Other pictures from Verrocchio's bottega probably exist, as, for example, two in the National Gallery of London wrongly attributed to Ant. Pollaiuolo—Tobias and the Angel (No. 781) and the very lovely Madonna and Angels (No. 296), both very brilliant and jewel-like in color. One of the angel faces in the latter picture strongly recalls the expression of Leonardo's heads, while the whole scheme of pure glowing color closely resembles that employed by Di Credi in his graceful but slightly weak pictures of the Madonna and Child. This exquisite painting, one of the gems of the National Gallery, may possibly have been painted from Verrocchio's design by Lorenzo di Credi while he was under the immediate influence of his wonderful fellow-pupil Da Vinci.[1]

---

[1] [Her name has no place in the Roman *Breviary*. Borromeo removed her name from the Ambrosian *Missal*. Saint's days do not come on movable feasts.—Am. Ed.]

In examining Verrocchio's work as a sculptor we are on surer ground. One of his earliest works was the beautiful marble medallion of the Madonna, over the tomb of Leonardo Bruni of Arezzo in the church of Santa Croce at Florence, executed some years after Bruni's death (1443). In 1472 Verrocchio completed the fine tomb of Giovanni and Piero de' Medici, between the sacristy and the lady chapel of San Lorenzo at Florence. This consists of a great porphyry sarcophagus enriched with magnificent acanthus foliage in bronze. Above it is a graceful open bronze grill, made like a network of cordage. In 1474 Verrocchio began the monument to Cardinal Forteguerra at the west end of Pistoia cathedral. The kneeling figure of the cardinal was never completed, and now lies in a room of La Sapienza, but the whole design is shown in what is probably Verrocchio's original clay sketch, now in the South Kensington Museum (see Fig.). Though this work was designed by Verrochio, the actual execution of it was entrusted to his assistant, the Florentine Lorenzetto. In 1476 Verrocchio modelled and cast the fine but too realistic bronze statue of David, now in the Bargello (Florence); and in the following year he completed one of the reliefs of the magnificent silver altar-frontal of the Florentine baptistery, that representing the Beheading of St. John. Verrocchio's other works in the precious metals are now lost, but Vasari records that he made many elaborate pieces of plate and jewellery, such as morses for copes, as well as a series of silver statues of the Apostles for the pope's chapel in the Vatican. Between 1478 and 1483 he was occupied in making the bronze group of the Unbelief of St. Thomas, which still stands in one of the external niches of Or San Michele (Florence). He received 800 florins [gold $2033.45] for these two figures, which are more remarkable for the excellence of their technique than for their sculpturesque beauty. The attitudes are rather rigid, and the faces hard in expression. Verrocchio's chief masterpiece was the colossal bronze equestrian statue of the Venetian general Bartolomeo Colleoni, which stands in the piazza of SS. Giovanni e Paolo at Venice. Verrocchio received the order for this statue in 1479, but had only completed the model when he died in 1488. In spite of his request that the casting should be entrusted to his pupil Lorenzo di Credi, the work was given to Alessandro Leopardi by the Venetian senate, and the statue was gilt and unveiled in 1496.[2] There appears to be no doubt that the model was completed by Verrocchio himself, and that nothing more than its reproduction in bronze should be attributed to the much feebler hand of Leopardi, who, however, has set his own name alone on the belly-band of the horse—**ALEXANDER · LEOPARDVS V. F. OPVS.** This is perhaps the noblest equestrian statue in the world, being in some respects superior to the antique bronze of Marcus Aurelius in Rome and to that of Gattamelata at Padua by Donatello. The horse is designed with wonderful nobility and spirit, and the easy pose of the great general, combining perfect balance with absolute ease and security in the saddle, is a marvel of sculpturesque ability.[3] Most remarkable skill is shown by the way in which Verrocchio has exaggerated the strongly marked features of the general, so that nothing of its powerful effect is lost by the lofty position of the head.[4] According to Vasari, Verrocchio was one of the first sculptors who made a practical use of casts from living and dead subjects. He is said also to have produced plastic works in terra-cotta, wood, and in wax decorated with color. As a sculptor his chief pupil was Francesco di Simone, the son of that Simone whom Vasari wrongly calls a brother of Donatello. Another pupil was Agnolo di Polo (Paolo), who worked chiefly in terra-cotta.



Clay sketch for the monument of Cardinal Forteguerra, showing the kneeling portrait of the cardinal, which is not in the actual monument; a very poor modern figure occupies its place.

Verrocchio died in Venice in 1488, and was buried in the church of St. Ambrogio in Florence. (J. H. M.)

VERSAILLES, a town of France, chef-lieu of the department of Seine-et-Oise and an episcopal see, lies 11 miles west-southwest of Paris, with which it is connected by railways on both banks of the Seine and by a tramway. The town owes its existence to the palace (460 feet above the sea) built by Louis XIV. The fresh healthy air and the nearness of the town to Paris have attracted many residents, and the interest attaching to the place draws crowds of visitors. The population in 1881 was 48,012; in 1886 it was 49,514 (commune 49,852), including about 10,000 military.

Plan of Versailles.

The three avenues of St. Cloud, Paris, and Sceaux converge in the Place d'Armes. Between them stand the former stables of the palace, now occupied by the artillery and engineers. To the south lies the quarter of Satory, the oldest part of Versailles, with the cathedral of St. Louis, and to the north the new quarter, with the church of Notre Dame. To the west a gilded iron gate and a stone balustrade shut off the great court of the palace from the Place d'Armes. On either side are allegorical groups, besides statues of the statesmen Suger, Sully, Richelieu, and Colbert, the soldiers Duguesclin, Bayard, Turenne, and Condé, the sailors Duquesne, Tourville, Duguay-Trouin, and Suffren, and the marshals Jourdan, Masséna, Lannes, and Mortier. At the highest point of the court there is an equestrian statue in bronze of Louis XIV., and to the right and left of this stretch the long wings of the palace, while behind it stand the central buildings one behind the other as far as the Marble Court. Here all the lines of construction meet, and here were the rooms of Louis XIV. To the north the Chapel Court and to the south the Princes Court, with vaulted passages leading to the gardens, separate the side from the central buildings. On the latter is the inscription "A toutes les gloires de la France," which Louis Philippe justified by forming a collection of five thousand works of art (valued at £1,000,000) [$4,860,000], commemorating the great events and persons of French history. The palace chapel (1696–1710), the roof of which can be seen from afar rising above the rest of the building, was the last work of Mansard. Opposite the altar is the king's gallery, which communicates with the rooms on the first floor of the palace. The ground-floor of the north wing on the garden side contains eleven halls of historical pictures from Clovis to Louis XIV., and on the side of the interior courts a gallery of tombs, statues, busts of kings and celebrities of France for the same period. The Halls of the Crusades open off this gallery, and are decorated with the arms of crusaders, kings, princes, lords, and knights, and with those of the grand-masters and knights of the military religious orders. On the first floor of the north wing on the garden side are ten halls of pictures commemorating historical events from 1795 to 1855; on the court side is the gallery of sculpture which contains the Joan of Arc of the Princess Marie of Orleans; and there are seven halls chiefly devoted to French campaigns and generals in Africa, Italy, the Crimea, and Mexico, with some famous war pictures by Horace Vernet. The second story has a portrait gallery. In the north wing is also the theatre built under Louis XV. by Gabriel, which was first used on the 16th of May, 1770, on the marriage of the dauphin (afterwards Louis XVI.) and Marie Antoinette. Here, on 2d October, 1789, the celebrated banquet was given to the Gardes du Corps, the toasts at which provoked the riots that drove the royal family from Versailles; and here the national assembly met from 10th March, 1871, till the proclamation of the constitution in 1875, and the senate from 8th March, 1876, till the return of the two chambers to Paris in 1879. The central buildings of the palace project into the garden. On the ground floor are the halls of celebrated warriors (once the anteroom of Madame de Pompadour), marshals, constables, and admirals. The Great Dauphin (son of Louis XIV.), the duke and duchess of Berri, the dauphin (son of Louis XV.), Madame de Montespan, Madame de Pompadour, and the daughters of Louis XV. all lived in this part of the palace. The gallery of Louis XIII., decorated with historical pictures of his and Louis XIV.'s time, leads to the halls surrounding the Marble Court. One of these contains many plans of battles, and at its door Louis XV. was wounded by Damiens in 1757. The lobbies of the ground floor are full of busts, statues, and tombs of kings and celebrated men. The famous state rooms are on the first floor. On the garden side, facing the north, are a series of seven halls—among them that of Hercules, till 1710 the upper half of the old chapel, where the dukes of Chartres, Maine, and Burgundy were married, and Bossuet, Massillon, and Bourdaloue preached; the Hall of Mercury, where the coffin of Louis XIV. stood for eight days after his death; and the Hall of Apollo, or throne room. To the front of the palace, facing the west, are the Galleries of War and Peace, with allegorical pictures, and the Glass Gallery, built by Mansard in 1678 (240 feet long, 34 wide, and 43 high), having 34 arches, 17 of which are filled with windows looking on the gardens and 17 with large mirrors. The gallery is overloaded with ornament, and the pictures by Lebrun, the trophies and figures of children by Coysevox, and the inscriptions attributed to Boileau and Racine all glorify Louis XIV. This gallery was used by him as a throne room on state occasions. Here the king of Prussia was proclaimed emperor of Germany on 16th January, 1871. Connected with the Gallery of Peace is the queen's room, occupied successively by Marie Thérèse, Marie Leczinska, and Marie Antoinette, where the duchess of Angoulême was born, the duchess of Burgundy died, and Marie Antoinette was almost assassinated on 6th October, 1789. The Coronation Hall is so called from David's picture of Napoleon's coronation, which is regarded as the artist's masterpiece. This hall opens on the marble, or queen's staircase. Behind the Glass Gallery on the side of the court are the rooms of Louis XIV. The Œil de Bœuf, named from its oval window, was the anteroom where the courtiers waited till the king rose. In it is a picture representing Louis XIV. and his family as Olympian deities; and it leads to the bedroom in which Louis XIV. died, after using it from 1701, and which Louis XV. occupied from 1722 to 1738. To the north of the Marble Court are the "petits appartements" of Louis XV. and to the south those of Marie Antoinette. Among the former is the Porcelain Gallery, where every year under Louis XVI. the best work made at Sèvres was displayed. On the second floor of the building surrounding the Stags Court Madame du Barry lived, and Louis XVI. afterwards worked at lockmaking. Marie Thérèse and Marie Leczinska had previously used the "petits appartements" of Marie Antoinette, one of the rooms of which is ornamented with woodwork of her time. In this part of the palace Madame de Maintenon and the duke of Burgundy had rooms, those of the latter being afterwards occupied by Cardinal de Fleury and the duke of Penthièvre. In the south wing of the palace, on the ground floor, are the Imperial Galleries (the first rooms of which were used by the duke and duchess of Bourbon under Louis XIV.) and the rooms occupied by the president of congress when the two legislative bodies meet together at Versailles. A sculpture gallery contains busts of celebrated scholars, artists, generals, and public men from the time of Louis XVI. onwards. In the south wing is also the room where the chamber of deputies met from 1876 till 1879, and where the congress has since sat to revise the constitution of 1875 and to elect the president of the republic. The first floor is almost entirely occupied by the Battle Gallery (394 feet long and 43 wide), opened in 1836 on the site of rooms used by Monsieur the brother of Louis XIV. and the duke and duchess of Chartres. It is lighted from above, and the walls are hung with pictures of French victories. In the window openings are the names of soldiers killed while fighting for France, with the names of the battles in which they fell, and there are more than eighty busts of princes, admirals, constables, marshals, and celebrated warriors who met a similar death. Another room is given up to the events of 1830 and the accession of Louis Philippe, and a gallery contains the statues and busts of kings and celebrities from Philip VI. to Louis XVI. In the rooms of the second story are portraits (mostly modern), sea-pieces, pictures of royal residences, and some historical pictures of the time of Louis Philippe.

The gardens of Versailles were planned by Le Nôtre. The best view is obtained from a balcony of the Glass Gallery. The ground falls away on every side from a terrace adorned with ornamental basins, statues, and bronze groups. Westwards from the palace extends a broad avenue, planted with large trees, and having along its centre the grass of the "Tapis Vert"; it is continued by the Grand Canal, 200 feet wide and 1 mile long. On the south two splendid staircases of 103 steps, 66 feet wide, lead past the Orangery to the Swiss Lake, 1312 feet long and 460 wide, beyond which is the wood of Satory. On the north an avenue, with twenty-two groups of three children, each group holding a marble basin, from which a jet of water rises, slopes gently down to the Basin of Neptune, remarkable for its fine sculptures and abundant water. The Orangery (built in 1685 by Mansard) is the finest piece of architecture at Versailles; the central gallery is 508 feet long and 42 wide, and each of the side galleries is 375 feet long. There are twelve hundred orange trees, one of which is said to be 465 years old, and three hundred other kinds of trees. The alleys of the parks are ornamented with statues, vases, and regularly-cut yews, and bordered by hedges surrounding the shrubberies. Between the central terrace and the Tapis Vert is the Basin of Latona or the Frogs, with a white marble group of Latona with Apollo and Diana. Beyond the Tapis Vert is the large basin of Apollo, who is represented in his chariot drawn by four horses; there are three jets of water, one 60, the others 50 feet in height. The Grand Canal is still used for nautical displays; under Louis XIV. it was covered with Venetian gondolas and other boats, and the evening entertainments usually ended with a display of fireworks. Around the Tapis Vert are numerous groves, the most remarkable being the Ballroom or Rockery, with a waterfall; the Queen's Shrubbery, the scene of the intrigue of the diamond necklace; that of the Colonnade, with thirty-two marble columns and a group of Pluto carrying off Proserpine, by Girardon; the King's Shrubbery, laid out in the English style by Louis Philippe; the beautiful Grove of Apollo, with a group of that god and the nymphs, by Girardon; and the basin of Enceladus, with a jet of water 75 feet high. Among the chief attractions of Versailles are the fountains and waterworks made by Louis XIV. in imitation of those he had seen at Fouquet's chateau of Vaux. Owing to the scarcity of water at Versailles, the works at MARLY-LE-ROI (*q.v.*) were constructed in order to bring water from the Seine; but part of the supply thus obtained was diverted to the newly-erected château of Marly. Vast sums of money were spent and many lives lost in an attempt to bring water from the Eure, but the work was stopped by the war of 1688. At last the waters of the plateau between Versailles and Rambouillet were collected and led by channels (total length 98 miles) to the gardens, the soil of which covers innumerable pipes, vaults, and aqueducts. The total volume of water annually brought to Versailles is about 175,000,000 cubic feet, of which two-fifths supply the town and the rest the park.

Beyond the present park, but within that of Louis XIV., are the two Trianons. The Grand Trianon was originally erected as a retreat for Louis XIV. in 1670, but in 1687 Mansard built a new palace on its site. Louis XV., after establishing a botanic garden, made Gabriel build in 1766 the small pavilion of the Petit Trianon, where the machinery is still shown by which his supper-table came up through the floor. It was a favorite residence of Marie Antoinette, who had a garden laid out in the English style, and lived an imaginary peasant-life. The Grand Trianon is a one-storied building with two wings, and has been occupied by Monsieur (Louis XIV.'s brother), by the Great Dauphin, the duke of Burgundy, the duchess of Orleans, Napoleon I., and Louis Philippe and his court. The duke and duchess of Orleans lived in the Petit Trianon. The gardens of the Grand Trianon are in the same style as those of Versailles, and there is a museum with a curious collection of state carriages, old harness, etc.

Apart from the palace, there are no buildings of interest in Versailles, the church of Notre Dame, built by Mansard, the cathedral of St. Louis, built by his grandson, the Protestant church, and the English chapel being in no way remarkable. The celebrated tennis court is now used as a museum. The large and sumptuous palace of the prefecture was built during the second empire, and was a residence of the president of the republic from 1871 to 1879. The library consists of 60,000 volumes; and the military hospital formerly accommodated 2000 people in the service of the palace. There are a statue of General Hoche and one of Abbé de l' Épée in the town. A school of horticulture was founded in 1874, attached to an excellent garden, near the Swiss Lake. Versailles is the seat of a school of artillery and of a school for non-commissioned officers of the artillery and engineers.

History.—Louis XIII. often hunted in the woods of Versailles, and built a small pavilion at the corner of what is now the Rue de La Pompe and the avenue of St. Cloud. In 1627 he entrusted Lemercier with the plan of a château, and in 1632 bought the land from François de Gondi, first archbishop of Paris, for £2640 [$12,830.40]. In 1661 Levau made some additions, and in 1682 Louis XIV. took up his residence at Versailles, and gave Mansard orders to erect the great palace in which the original buildings disappeared. Fabulous sums were spent on the palace, gardens, and works of art, the accounts for which were destroyed by the king. Till his time the town was represented by a few houses to the south of the present Place d'Armes; but land was given to the lords of the court and new houses sprang up, chiefly in the north quarter. Under Louis XV. the parish of St. Louis was formed to the south for the increasing population, and new streets were built to the north on the meadows of Clagny, where in 1674 Mansard had built at Louis XIV.'s orders a château for Madame de Montespan, which was now pulled down. Under Louis XVI. the town extended to the east and received a municipality; in 1802 it gave its name to a bishopric. In 1783 the peace by which England recognized the independence of the United States was signed at Versailles. The states-general met here on 5th May, 1789, and on 20th June, took the solemn oath by which they bound themselves never to separate till they had given France a constitution, and which led to the riots of 5th and 6th October. Napoleon, Louis XVIII., and Charles X, merely kept up Versailles, but Louis Philippe restored its ancient splendor at the cost of £1,000,000, [$4,860,000]. In 1870 and 1871 the town was the headquarters of the German army besieging Paris. After the peace Versailles was the seat of the French national assembly while the commune was triumphant in Paris, and of the two chambers till 1879, being declared the official capital of France. Versailles was the birthplace of Hoche, Abbé de l'Épée, Philip V. of Spain, Louis XV., Louis XVI., Louis XVIII., Charles X., Count de Maurepas, Prince de Polignac, Marshal Berthier (Prince of Wagram), Houdon, the sculptor, Ducis, the poet, Callet, the mathematician, and Ferdinand de Lesseps.

(G. ME.)

VERSECZ, a royal free town in the county of Temes, Hungary, 40 miles south of Temesvár. It is partly fortified and is the seat of a Greek bishop. Amongst its principal institutions are a high college for girls, a gymnasium, and a real school. Versecz is one of the principal wine-producing centres in the kingdom, its yearly export amounting to an average of five and a half million gallons. There is also a good trade in rice and silk. The population numbered 22,329 in 1880.

VERTEBRATA.

Lamarck's and Cuvier's classifications.

VERTEBRATA, the name of a great branch or phylum of the Animal Kingdom which comprises those animals having bony "vertebræ", or pieces of bone jointed so as to form a spinal column. The first recognition of the group is due to Lamarck (1797), who united the four highest classes of Linnæus's system as "animaux à vertèbres," whilst distinguishing the rest of the animal world as "animaux sans vertèbres." The same union of the four Linnæan classes had been previously made by Batsch in 1788, who, however, proposed for the great division thus constituted, the name "Knochenthiere." The significance of Lamarck's classification was materially altered, and the foundation laid of our present attempts to represent by our classifications the pedigree of the animal kingdom, when Cuvier propounded his doctrine of "types," and recognized the *Vertebrata* as one of four great types or plans of structure to be distinguished in the animal world (I).[1]

Essential structures of Vertebrates.

The *Vertebrata* of Lamarck and Cuvier included beasts, birds, reptiles, and fishes, and until recently the group was considered as one of the most sharply limited in the animal kingdom. The progress of anatomical studies very soon rendered it clear that all *Vertebrata* did not possess bony vertebræ; for besides the commoner sharks and skates, with their purely cartilaginous skeletons, naturalists became acquainted with the structure of fishes, such as the sturgeons and the lampreys, which possess no vertebræ at all, but merely a continuous elastic rod (the notochord) in the place of the jointed spinal column. The muscles and their skeletal septa were seen in these fishes to be arranged in a series of segments attached to the sides of this continuous rod; and hence the structural character of bony vertebræ, as distinguishing the *Vertebrata*, gave place to the character of segmental arrangement of the muscles of the body-wall, such muscles being supported by a skeletal axis which might be itself unsegmented (notochord), or replaced by segmental cartilaginous or bony vertebræ. The studies of embryologists furnished a sound foundation for this conception by demonstrating that in the embryos of *Vertebrata* with true vertebræ these structures are preceded by an unsegmented continuous notochord. The inquiry into the structural characteristics of *Vertebrata* led further to the recognition of several additional points of structure, the combination of which was present only in the group which had been recognized by Lamarck on superficial grounds. It was found that all *Vertebrata* possess laterally-placed passages leading from the pharynx to the exterior, serving in the aquatic forms as the exits for water taken in by the mouth, and provided with vascular branchial processes, whilst in the embroyos of the higher air-breathing classes they appear only as temporary structures. It was further established that the great mass of nervous tissue lying dorsally above the spinal column, and known as the cerebro-spinal nerve-centre or brain and spinal cord, is in all cases a tube, and originates as part of the dorsal surface of the embryo, which becomes depressed in the form of a long groove and finally closed in by the adhesion of its opposite edges. thus forming a tube or canal. The three structures, —notochord, gill-slits, and tubular dorsal nerve cord, —were more than twenty years ago recognized as characterizing, together with the metameric segmentation of the musculature of the body-wall, all *Vertebrata* at some one or other period of their existence.

Question of Vertebrate ancestry.

Kowalewsky's labors.

The establishment by Darwin of the doctrine of organic evolution in 1859 led naturalists consciously to make the attempt to determine the genetic affinities and the probable ancestry of the various groups of animals, and enabled them to recognize in the classifications by "type," and other such conceptions of earlier systematists, the unconscious striving after genealogical representation of the relationships of organic beings. The question naturally arose in regard to the *Vertebrata*, as in regard to other great divisions of the animal kingdom. What were the characters of the earliest forms, the ancestors of those now living? Then came the further questions as to whether any surviving *Vertebrata* closely resemble the ancestral form, and whether any animals are still in existence which retain the general characters of those primeval forms which were the common ancestors at once of Vertebrates and of other large and equally well-marked phyla or branches of the animal kingdom, such as the Molluscs, the Annulates, etc. This fascinating subject of inquiry received its most important impulse from the embryological investigations of the Russian naturalist Kowalewsky, and has been for nearly a quarter of a century the fertile source of speculation and its indispensable accompaniments, new observation and research. Kowalewsky published in 1866 an account of the embryology of the lowest and simplest of then recognized Vertebrates, the lancelet (*Amphioxus lanceolatus*), in which he attempted to trace, cell for cell from the fertilized egg-cell, the origin of the characteristic Vertebrate organs of this animal (2). This work alone would not have acquired historic importance, although it is the starting point of what may be called strict cellular embryology, as compared with the less severely histological works of previous students. But it was accompanied by an account (3) of the development of *Ascidia mamillata*, one of the so-called Tunicate Molluscs, in which it was demonstrated by Kowalewsky, not only that this supposed Mollusc possesses when first hatched from its egg-envelope a notochord, pharyngeal gill-slits, and a tubular dorsal nerve-chord and brain, but that these three characteristically Vertebrate features of organization originate from the same cell-layers of the embryo, and in essentially the same way as in *Amphioxus*, whilst the cell-layers themselves originate from the egg-cell in the two animals by precisely similar movements of cell division and invagination (see Figs. 1 and 2). Kowalewsky's discoveries established once for all that the Ascidian tadpole is identical in three very special and distinct features of structure with the frog's tadpole. No classification which pretended to set forth the genetic affinities of animals could henceforth separate the Ascidian from the *Vertebrata*, and with it the Ascidian brought the whole series of *Tunicata*.

Admission of *Tunicata* as Vertebrates.

The admission of *Tunicata* as a group of *Vertebrata* was proposed by the present writer as long ago as 1877 (4); but it required the intermediate proposition by Balfour of a group *Chordata*, to comprise the two divisions *Tunicata* and *Vertebrata*, in order to render the final admission of *Tunicata* to their proper association with the *Vertebrata* of Cuvier palatable to systematists. As an objection to the simple inclusion of *Tunicata* in the great phylum *Vertebrata* it has been urged that *Tunicata* do not possess vertebræ,—a proposition which is equally true of *Amphioxus* and of some Fishes. Shifting the objection, some writers have maintained that the vertebration of the *Vertebrata* may be understood as having reference to the segmentation of the muscles of the body-wall, which is exhibited by all Cuvier's *Vertebrata* without exception, inclusive of *Amphioxus*, though not by *Tunicata*. To this it may be replied that the Ascidian tadpole, and more clearly

---

[1] These numerals refer to the bibliography at the end of the article.

the free-swimming Tunicate *Appendicularia* (see Fig. 9), do exhibit a segmentation of the muscles of the hinder part of the body-wall similar to and identical with that of *Amphioxus*, whilst no such strict application of a name in its original descriptive sense is desirable in systematic nomenclature. All *Gastropoda* (it has been pointed out) are not gastropodous; all *Arthropoda* are not arthropodous; and many *Echinoderma* are not echinodermous. It is, in the present writer's opinion, better to retain an historic and familiar name for the great branch of the animal pedigree to which it has become necessary to admit forms whose affinities therewith were at one time unsuspected rather than to sacrifice historical significance to a futile striving after etymological accuracy.

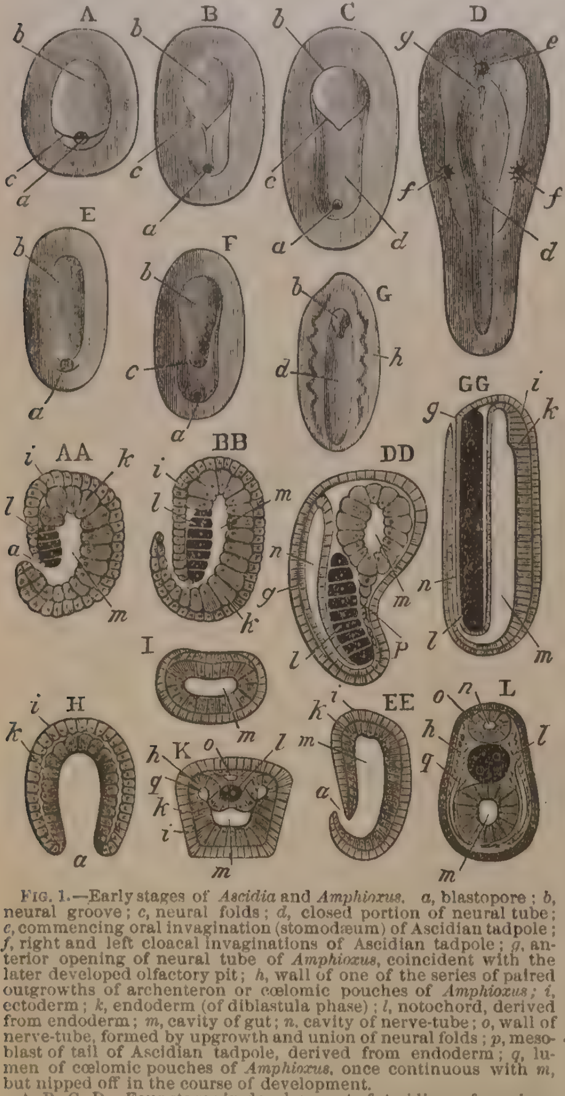

Fig. 1.—Early stages of *Ascidia* and *Amphioxus*. *a*, blastopore; *b*, neural groove; *c*, neural folds; *d*, closed portion of neural tube; *e*, commencing oral invagination (stomodæum) of Ascidian tadpole; *f*, right and left cloacal invaginations of Ascidian tadpole; *g*, anterior opening of neural tube of *Amphioxus*, coincident with the later developed olfactory pit; *h*, wall of one of the series of paired outgrowths of archenteron or cœlomic pouches of *Amphioxus*; *i*, ectoderm; *k*, endoderm (of diblastula phase); *l*, notochord, derived from endoderm; *m*, cavity of gut; *n*, cavity of nerve-tube; *o*, wall of nerve-tube, formed by upgrowth and union of neural folds; *p*, mesoblast of tail of Ascidian tadpole, derived from endoderm; *q*, lumen of cœlomic pouches of *Amphioxus*, once continuous with *m*, but nipped off in the course of development.

A, B, C, D. Four stages in development of *Ascidia*, surface views showing gradual enclosure of neural area. E, F, G. Three similar stages in development of *Amphioxus*, AA. Vertical antero-posterior median section of A. BB. Similar section of B. DD. Similar section of a stage a little earlier than D. EE. Similar section of E (*Amphioxus*). GG. Similar section of embryo represented in G. H. Transverse section of diblastula stage of *Amphioxus*, with widely open blastopore (earlier than A or E). I. Transverse (right and left) section about the middle of F, showing neural area. K. Transverse section about middle of G, showing nerve-tube, notochord, and cœlomic pouches or mesoblastic somites *q*. L. Transverse section of a much further advanced embryo of *Amphioxus*, showing nerve-tube, notochord, and gut: the walls of the cœlomic pouches are now converted into muscular tissue and the pouch cavity (*q*) compressed. (All the figures after Kowalewsky, 17, 18.)

The admission of *Tunicata* to association with Cuvier's *Vertebrata* has been followed by a further innovation. The remarkable marine worm *Balanoglossus*—originally described by Della Chiaje at the end of the 18th century—was shown in 1866 by Kowalewsky (5) to possess a series of pharyngeal gill-slits similar to those of *Tunicata* and *Amphioxus*. Later researches by Bateson (6) have demonstrated that *Balanoglossus* develops in embryonic life a short notochord, whilst its nerve-chord is, in part at least, tubular, and similar in position and relations to the median epidermal tract by the infolding of which the nerve-tube of *Tunicata* and the other *Vertebrata* is formed. Hence it seems impossible to exclude *Balanoglossus* from a place in the phylum *Vertebrata*. The possession of pharyngeal gill-slits alone might not justify the association; but, when this is combined with the presence of the notochord, though rudimentary and with a special condition and position of the main nerve-centre, it becomes impossible to ignore *Balanoglossus* in our conception of the Vertebrate phylum. The recent discoveries of Harmer (7) with regard to *Cephalodiscus* will hereafter render it necessary to associate that form, and in all probability *Rhabdopleura* also, with *Balanoglossus* in the Vertebrate phylum. The further consequences of such an association in regard especially to the affinities of *Polyzoa* and of *Gephyræa* open up a large field of speculation and of consequent embryological and anatomical research.

Inclusion of *Balanoglossus* in Vertebrate phylum.

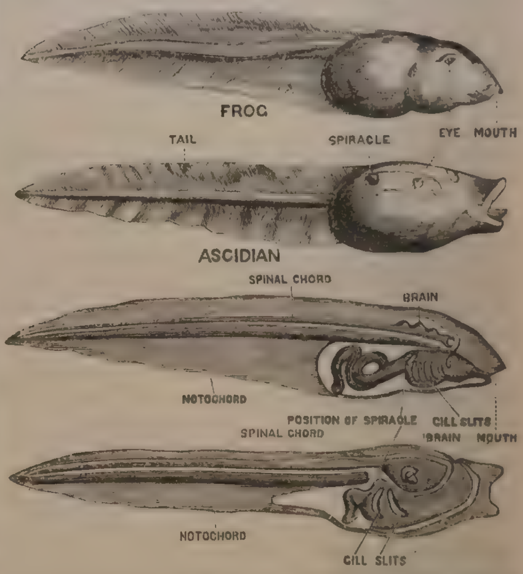

Fig. 2.—Diagram illustrating relationship of tadpoles of Frog and Ascidian. The two upper figures represent surface views of the tadpoles; the two lower ones show in place the chief Vertebrate organs, viz., notochord, gill-slits, nerve-tube, and myelonic eye. (From Lankester's *Degeneration*.)

Ancestral form of Vertebrates.

The Cuvierian *Vertebrata Amphioxus*, *Tunicata*, and *Balanoglossus* being thus indisputably connected by a remarkable combination of structural points, which admit of no explanation consistent with the principles of evolutional morphology except that of the genetic relationship of the forms thus enumerated, we are at once confronted by those questions as to the ancestral history of *Vertebrata* which have been already mentioned above as stimulated by Kowalewsky's discoveries. Undoubtedly *Amphioxus* is lower and simpler in structure than any Fish, *Tunicata* as low as or lower than *Amphioxus*, and *Balanoglossus*, in some respects, more archaic than either *Amphioxus* or the Ascidian tadpole. The first tendency arising from the discovery of the affinities of these simpler forms with the Cuvierian *Vertebrata* was to see in them the representatives of the ancestors of all *Vertebrata*. *Amphioxus* has been pointed to by authorities in morphology as the living presentation of our common Vertebrate ancestor; a similar position corresponding to an earlier stage of development has been admitted by no less an authority than Darwin for the Ascidian. It appears, nevertheless, that all such simple solutions of the problem of Vertebrate ancestry are without warrant. They arise from a very common tendency of the mind, against which the naturalist has to guard himself,—a tendency which finds expression in the very widespread notion that the existing anthropoid apes, and more especially the gorilla, must be looked upon as the ancestors of mankind, if once the doctrine of the descent of man from ape-like forefathers is admitted. A little reflection suffices to show that any given living form, such as the gorilla, cannot possibly be the ancestral form from which man was derived, since *ex hypothesi* that ancestral form underwent modification and development, and in so doing ceased to exist. The same considerations apply to the question of the ancestry of *Vertebrata*. Probably no existing low form of Vertebrate *closely* represents the ancestral form by the modification of which higher forms have been developed. We have no justification for assuming that such low forms do more than present to us a collateral branch of the family, and that collateral branch must, in all probability, have experienced its own special series of modifications of structure. Not only this, but we have no sufficient ground for assuming that, even in respect of the simplicity of their structure, any given animal forms at present existing exhibit a mere survival of a corresponding degree of simplicity in their remote ancestors. Such an assumption was almost universally made, until a more correct view was pressed on the attention of naturalists by Dr. Anton Dohrn, the founder of the zoological station of Naples (8.) So far from its being the case that simplicity of organization necessarily implies the continuous hereditary transmission of a low stage of structural development from remote ancestors, there are numerous instances in which it is certain that the existing simplicity of structure is due to a process of degeneration, and that an existing form of simple structure is thus descended from ancestors of far higher complexity of organization than itself. Such are various parasitic worms and *Crustacea*. The evidence in favor of the occurrence of progressive simplification of structure or degeneration, in place of progressive elaboration, depends (1) upon the comparison of the adult structure of the degenerate organism with that of its nearest allies, by which it is often rendered clear that the *ensemble* of the organization of the simpler organism cannot be explained on the hypothesis that it represents an ancestral or archaic condition common to it and its more elaborate congeners, and (2) on the direct evidence of individual development or life-history. The latter evidence is conclusive, when we find, as in the case of Cirrhipede Crustaceans and of Ascidian Tunicates, that the embryó on its way to the adult condition passes through stages of development presenting a higher degree of organization than that ultimately reached, so that, as in the Cirrhipede larva and the Ascidian tadpole, the young form resembles allied organisms of a higher stage of development, and subsequently degenerates from the point of progressive elaboration to which it had attained, and becomes greatly simplified in the final stage of its growth. Conclusive as such evidence is, there is no law of development which necessitates its preservation. If it be an advantage to the organism, the full force of heredity has play, and what are called the "recapitulative phases" of ancestral development are passed through by the individual in the course of development from the egg. But with remorseless thoroughness all such hereditary tendencies may be removed when such removal is an advantage to the organism, and the development from the egg *may* proceed directly to the adult degenerate form. Such is the case with many *Tunicata*, the young of which never exhibit notochord and tadpole form; indeed, were it not for the preservation of a few exceptional cases, like that of the Ascidian section of the group, we should have no direct evidence of the degeneration of *Tunicata* from tadpole-like ancestry.

Arguments from simplicity of structure.

Hypothesis of degeneration.

The general result of the considerations which have been urged with regard to degeneration is this, that it is *prima facie* as legitimate an hypothesis, that any existing animal has developed by progressive simplification from more elaborate ancestors, as it is that such an animal has developed by a continuous and unbroken progress in elaboration from simpler ancestors; and we are specially called upon to apply the hypothesis of degeneration where the animal under consideration is likely from its mode of life to have undergone that process. Such modes of life, tending to degeneration, are parasitism, sessile or adherent habit, burrowing in the sea-bottom, and diffuse feeding. The animal which pursues living prey, and contends with other organisms for the dominion of the regions of earth and water that are flooded with light and richly supplied with oxygen gas, is the animal which represents the outcome of a longer or shorter period of progressive elaboration. It is worth while noting in parenthesis that in all cases the "whirligig of time" has probably brought its revenges, and that the ancestry of a form evolved through a long period of progressive elaboration was at an antecedent period subject to simplification and degeneration, whilst in the past records of the present exemplars of the latter process there must certainly have been long stretches of continuous elaboration.

Genealogical tree.

Applying these considerations to the construction of the genealogical tree of *Vertebrata*, we find that the task is by no means simplified. We cannot with the earliest evolutionists adopt a scale or ladder-like series, placing the simplest form on the lowest step; nor can we be satisfied with a tree-like arrangement, in which the forms at the ends of the branches are always more elaborate than those nearer the trunk. Our genealogical tree will more strictly conform to that of a parvenu human family, if we take worldly prosperity in the latter case as corresponding to elaboration of structure in the former. The strict family genealogist will include in the successive ramifications of the tree the five sons of the founder of the family, one of whom remained an agricultural laborer, whilst two became brewers and two emigrated. The cousins in the next generation will be set forth in place, the sons of one brewer becoming paupers, whilst those of the other advance to the position of Government employés, and one to the peerage. Thus in successive branchings of the family history there may be alternate progress and degeneration. And so it must be in the genealogical trees constructed by the naturalist; the fact that a branch is later in origin will not imply that it is higher in elaboration than those below it, and accordingly we must not expect to draw our trees so as to be able to trace all simpler forms to lower off-sets of the tree.

Divisions of Vertebrate phylum.

The structural features of those animals which must be admitted to the Vertebrate phylum in consequence of possessing notochord, pharyngeal gill-slits, and dorsal nerve-plate, tubular or unrolled, are such as enable us very readily to group them in four great divisions, which appear to be equally distinct from one another. As to what may be the genetic relations to one another of these four groups we will inquire subsequently; for the present we term these groups "branches." They are as follows:

Phylum VERTEBRATA.

Branch *a—Craniata* (Cuvierian *Vertebrata*).
" *b—Cephalochorda* (*Amphioxus*).
" *c—Urochorda* (*Tunicata*).
" *d—Hemichorda* (*Balanoglossus*).

The *Vertebrata* thus limited may be defined as Cœlomate *Enterozoa* (*Metazoa*) with well-developed cœlom. In all, with the exception of the more degenerate members of *Urochorda*, an elastic skeletal rod—the notochord—is developed dorsally by an outgrowth of cells forming the wall of the primitive archenteron; the notochord may or may not persist in adult life. Pharyngeal gill-slits, which may or may not persist in adult life, are developed in all Vertebrates. In all, except in certain *Urochorda*, the chief nerve-centre has the form of a dorsal, median, elongate tract, derived from the epiblast, which becomes sunk below the surface and invaginated so as to form a tube. In all there is a tendency to metameric repetition of parts, which may find its expression in a strongly-marked segmentation of the musculature of the body-wall and its skeleton, or may be recognizable only in a limited degree, as exhibited by the successive gill-slits or successive gonads.

We shall now examine the distinctive features of each of these large groups, and form an estimate of their relations to one another, and of their probable ancestry, this being the task to which we must limit ourselves in the brief space here afforded.

The Craniata.

Characters of *Craniata*.

The *Craniata* are *Vertebrata* in which the tubular cerebro-spinal nerve-mass is swollen anteriorly to form a brain, consisting primarily of three successive vesicles, in connection with the anterior of which the special nerves of the olfactory organs and of the eyes originate. The notochord, whilst extending posteriorly to the extremity of the body, does not reach quite so far forward anteriorly as the termination of the nerve-tube. A cartilaginous cranium or brain-case develops round the anterior extremity of the nerve-cord, and rises up laterally so as to enclose and protect the brain (hence *Craniata*). Cartilage is developed in other parts of the body as a skeletal substance, though it may be subsequently replaced in the cranium, as elsewhere, by bone. The longitudinal muscles of the body-wall are divided by transverse fibrous septa into a series of segments, varying in the adult from ten to one hundred or more in number. Cartilaginous neural arches, corresponding in number and position to the fibrous septa, and resting on the notochord, are developed so as to protect the nerve-chord. Cartilaginous bars also pass outwards, with a direction at first horizontal and then ventral, from the sides of the notochord into the intermuscular fibrous septa. Very generally, but not always, a tubular cartilaginous sheath forms round the notochord; this sheath with rare exceptions becomes segmented to form a series of vertebral bodies, which lie in the planes of the fibrous intersegmental septa, and, increasing in thickness by encroaching upon the substance of the notochord, finally obliterate it almost entirely.

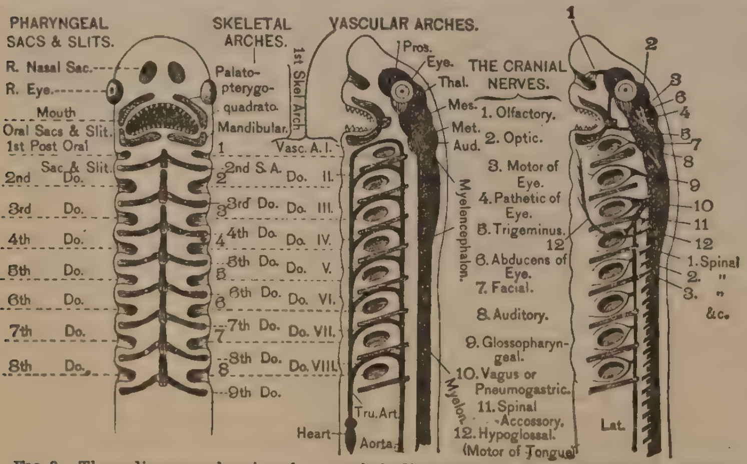

Fig. 3.—Three diagrams showing characteristic disposition of gill-slits, skeletal arches, vascular arches, and furcal nerves in a primitive ideal Craniate. The following abbreviations require explanation: *pros.*, prosencephalon; *thal.*, thalamencephalon; *mes.*, mesencephalon; *met.*, metencephalon; *aud.*, otocyst or auditory sac; *tru. art.*, truncus arteriosus. (Original.)

The pharyngeal slits follow closely upon the mouth, and in existing *Craniata* never number more than eight pairs (see Fig. 3). They are separated from one another and their apertures strengthened by a series of cartilaginous hoops, the first of which, that between the mouth and the first gill-slit, forms the primitive upper and lower jaw in all but the small and degenerate group *Cyclostoma*. The gill-slits when functional are generally protected by an opercular fold of the body-wall, which overhangs them and corresponds to the epipleural fold of *Amphioxus*, the collar of *Balanoglossus*, and doubtfully to the wall of the atrial chamber of *Urochorda*. The extension of this fold along the sides of the middle third of the body (between the pharyngeal region and the anus) acquired in ancestral *Craniata* the function of a continuous right and left lateral fin (see Fig. 4). At the same time a continuous median fin, corresponding to the dorsal, caudal, and anal fins of existing Fishes, was developed. In both lateral and median fins a cartilaginous skeleton was developed, consisting of a basal longitudinal bar, supporting a number of rods like the teeth of a comb. The primitive form of fin skeleton is retained in the median fins of some sharks; the primitive lateral fin has in all cases either entirely disappeared (*Cyclostoma*) (as has their anterior extension, the operculum, in many cases) or it has become, together with its skeletal elements, concentrated in two regions—forming the pectoral and the pelvic paired appendages or limbs, with their respective girdles.

The cerebro-spinal nerve-centre and the disposition of the nerves issuing from it present a remarkable complexity, and at the same time uniformity, of structure in all *Craniata* (see Fig. 5). The foremost of the three primary cerebral vesicles gives rise to paired anterior outgrowths, the prosencephala, to a median dorsal outgrowth, the stalk of the pineal eye (rudimentary in all existing *Craniata*), and to a median ventral outgrowth, which is met by an invagination of the epidermis of the oral cavity forming the pituitary body, further, to a pair of lateral outgrowths, which become the right and left optic nerves and retinæ respectively. The modifications of the hindmost of the three primary vesicles are also extremely definite and persistent throughout the group: its anterior dorsal surface enlarges and becomes the cerebellum (the metencephalon), whilst the cavity of its hinder part (the medulla oblongata or the epencephalon) becomes comparatively wide, and is covered dorsally by a thin membrane only, in which nervous tissue does not take a part. The intermediate primary cerebral vesicle (the mesencephalon) does not give rise to outgrowths.

In all *Craniata* nerves are given off from the cerebro-spinal cord or tube with great regularity, one right and left in each successive myomere or segment of the body-wall. Each nerve has two roots, a dorsal (sensory) and a ventral (motor). A commissure between each successive pair of deep or intestinal branches of the spinal nerves forms the so-called sympathetic nerve-cords, one on each side of the vertebral column. Nerves similar to the spinal nerves, but not identical with them, are given off from the brain, and perforate the cranial box right and left. In all *Craniata* there are ten pairs of nerves which originate thus, and in the higher forms two more pairs (elsewhere spinal) are included amongst those which thus perforate the cranium (spinal accessory and hypoglossal). The order and character of the cranial nerves are the same in all *Craniata*. The first (olfactory) and the second (optic) are unlike spinal nerves in both distribution and origin. As we pass backwards along the series, the cranial nerves are found to resemble more and more the ordinary spinal nerves. Hence it has been inferred that the cranial region consisted at one time of a number of distinct myomeres (as many as nine), which have become fused and modified to form the typical craniate "head." The oculo-motor or 3d nerve indicates the first of these segments, the trochlear or 4th nerve the second, the abducens or 6th the third, the facial and auditory (7th and 8th) the fourth, the glosso-pharyngeal or 9th the fifth, and the vagus or 10th, with certain of its branches supposed to have been originally distinct nerves, the sixth, seventh, eighth, and ninth. It is probable that in *Craniata* the metamerism of the gill-slits does not correspond to the metamerism of the body-wall. The mouth and each successive gill-slit are related to a bifurcate branch of a cranial nerve (furcal nerve) in lower *Craniata* (see Fig. 3); these furcal nerves do not correspond, so far as we can at present judge, with cranial myomeres.

The lateral pair of eyes (as opposed to the rudimentary pineal or parietal eye) present a striking uniformity of origin and structure throughout *Craniata*. Not only are they uniformly developed from three elements, viz., the retinal cup which grows out from the anterior of the primary cerebral vesicles, the epidermal lens which grows inwards from the surface of the skin, and the connective tissue between these two, but we find that the muscles attached to the eyeball are identical throughout the series: that is, the superior, inferior, and internal rectus, and the inferior oblique muscles represent the first cranial myomere, the superior oblique represent the second, and the external rectus represent the third cranial myomere.

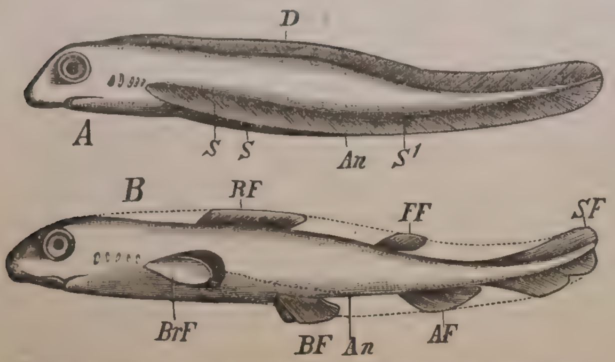

FIG. 4.—A. Hypothetical primitive Fish, with continuous lateral fins S, S (paired right and left), confluent with median azygos fin(*An*), the post-anal part of which is marked S′, whilst its dorsal part is marked D. B. Actual Fish, showing relation of isolated lateral and median fins to original hypothetical fins of the upper figure. BrF, left pectoral fin (paired); BF, left pelvic fin (paired); AF, anal (post-anal) azygos fin; SF, caudal azygos fin; RF and FF, anterior and posterior azygos dorsal fins; An, anus. (From Wiedersheim.)

The olfactory sacs are paired in all except *Cyclostoma*, in which they are represented by a single sac which may or may not be archaic in its azygos character. The auditory sacs are paired organs which develop as invaginations from the surface,—the orifice of invagination closing up,—at the hinder part of the cranial region. They present a gradually increasing complexity of form as we pass from aquatic to terrestrial forms, but are identical in essential structure throughout.

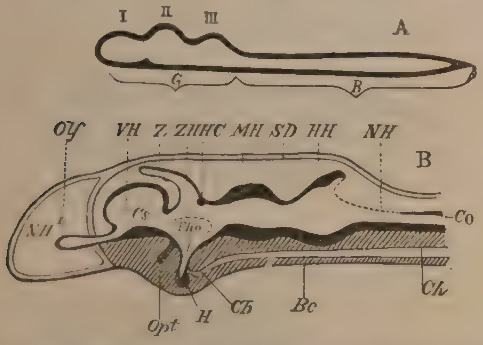

FIG. 5.—Diagrams of Craniate brain. A. Embryonic condition of neural tube. G, Cerebral portion; R, Spinal cord; I, II, III, three primary cerebral vesicles. B. Longitudinal section of adult brain, applicable to any and every Craniate Vertebrate. *Bc*, Floor of skull; *Ch*, notochord; *SD*, roof of skull; NH¹, nasal cavity; VH, fore-brain, prosencephalon, or cerebrum; *Olf*, olfactory lobe; *Cs*, corpus striatum; ZH, thalamencephalon, corresponding to primary anterior vesicle, from which the prosencephalon has grown out as well as *Z*, the epiphysis or pineal body; I, infundibulum, with attached hypophysis or pituitary body H; *Opt*, optic nerve; *Tho*, thalamus opticus; HC, posterior commissure; MH, mesencephalon (*corpora quadrigemina* or optic lobes or mid-brain); HH, cerebellum or metencephalon; NH, medulla oblongata or epencephalon (the reference line touches the membranous roof of the so-called "fourth ventricle" of the brain); *Co*, canal of the spinal cord or myelon. (From Wiedersheim.)

All *Craniata*, except some Fishes, possess a muscular process on the floor of the oral cavity which may carry teeth, or act as a licking organ, or assist in suction. This is the tongue.

All *Craniata*, with degradational exceptions, possess an outgrowth, single or paired, of the post-pharyngeal region of the alimentary canal, which is filled with gas. In many Fishes this becomes shut off from the gut; in others it remains in communication with the gut by an open duct. In Fishes it functions as a hydrostatic apparatus. In terrestrial *Craniata* it is subservient to the gas-exchange of the blood and becomes the lungs.

All *Craniata* have a large and compact liver; and a pancreas is also uniformly present, except in *Cyclostoma*, some bony Fishes, and the lower *Amphibia*.

All *Craniata* have a thick-walled muscular heart, which appears first as an "atrium," receiving the great veins, attached to a "ventricle" by which the blood received from the atrium is propelled through a number of arteries, right and left, corresponding in number to the pharyngeal gill-slits between which they pass. A præatrial chamber (the sinus) and an extra-ventricular chamber (the conus) are added to the primitive chambers; but the most important modifications arise in consequence of the development of pulmonary respiration and the gradual separation of the cavities of the heart by median septa into a double series, a right and a left. The plan of the great arteries in all *Craniata* is in origin the same, and is determined by the primitive existence of a branchial circulation in the gill-slits, which is obliterated in higher forms. Similarly the plan of the great veins is identical, the primitive posterior vertebral veins of lower *Craniata*, though persistent in higher members of the group, having their function gradually usurped by the excessive development of the renal vein, and of renal-portal and ultimately of iliac veins.

All *Craniata* have a lymphatic system or series of channels by which the exudation from the capillary bloodvessels is returned to the vascular system. It includes in its space-system the cœlom and a variety of irregular and canalicular spaces in the connective tissues. Masses of spongy tissue (adenoid tissue, lymphatic glands) exist, through which the lymph filters, and there acquires corpuscular elements as well as chemical elaboration. At various points in various *Craniata* pulsating or simple communications are established between the lymphatic system and the veins. A special and characteristic communication is established in the spleen, an organ which is found in all *Craniata*, either as a single mass or as scattered masses of spongy tissue in which bloodvessels and lymphatics unite.

The renal organs of *Craniata* are primitively a series of nephridia corresponding in number to the myotomes of the mid-region of the body in which they exist. They are connected in the simplest *Craniata* by a right and a left archinephric duct, which appear to be in origin lateral grooves of the epidermal surface. This primitive renal system has been modified in some lower forms (*Cyclostoma* and Teleostean Fishes) by the atrophy of its anterior portion. But in all other *Craniata* it acquires relations to the gonads or ovary and testes, so that an anterior portion of the archinephros and a corresponding longitudinal tract of the duct become separated to serve as oviduct, a middle portion to serve as sperm-duct, while a posterior portion retains exclusively or shares with the middle portion the function of urinary excretion. The male and female gonads are, with the rarest exceptions, developed in distinct individuals, though the rudiments of the suppressed gonad may in some cases (*Amphibia*) be traceable in either sex.

Subdivisions of *Craniata*.

The group of Craniate *Vertebrata* thus anatomically described, whilst retaining the essential unity indicated, presents an immense variety of modifications. The chief modifications are distinctly traceable to and accounted for by mechanical and physiological adaptation to a terrestrial and air-breathing life, as opposed to the earlier aquatic and branchial condition. The existing forms of *Craniata* have been arrested at several points, in the progress towards the most extreme adaptation to terrestrial conditions, which is presented by those forms that can not only breath air and live on dry ground but fly habitually in the air. The organs most obviously affected by this progressive adaptation are the skin, the skeleton, especially of the limbs, the pharyngeal gills, and the air-bladder. This fact will appear most clearly in the subjoined classification of *Craniata*; for space does not permit us to pursue further the history of these modifications.

Classification of CRANIATA.[1]

Grade A. CYCLOSTOMA.

---

[1] The classes here enumerated are described in separate articles, whilst *Cyclostoma* and *Dipnoi* are included in the article ICHTHYOLOGY.

Class I. *Myxinoidea.*
II. *Petromyzontia.*
Grade B. Gnathostoma.
Grade a. **Branchiata heterodactyla.**
Class I. *Pisces.*
II. *Dipnoi.*
Grade b. **Branchiata pentadactyla.**
Class. *Amphibia.*
Grade c. **Pentadactyla lipobranchia.**
Branch a. Monocondyla. *Branch b. Amphicondyla.*
Class I. *Reptilia.* Class. *Mammalia.*
II. *Aves.*

Ancestral form of *Craniata.*

If we now briefly consider what must have been the common ancestral form from which these *Craniata* have proceeded, making use of such internal evidence as their structure affords, we find that we get no further back than such an animal as would fit the description given above, with the exception that we should be warranted in substituting in the ancestor a pair of continuous lateral fins, with comb-like cartilaginous skeleton, in place of the two pairs of fins, or their total defect, seen in living *Craniata.* We get no clear suggestion from the study of *Craniata* themselves as to the meaning of the curious shape of the brain and its outgrowths (though the pineal outgrowth has recently been explained as an eye), nor as to the original genesis of the notochord. We should, however, be justified in representing that region which now corresponds to the hinder part of the skull and brain as more fully developed and segmented, so as to give a series of separate myotomes and perhaps separate nerves corresponding to the several furcal branches of the vagus; and we may very well suppose that the number of pharyngeal gill-slits was larger in the ancestral than in any living form, though it seems improbable that in any true Craniate did each gill-slit correspond to a distinct muscular segment.

An attempt to go further than this has been made by Dr. Anton Dohrn by the method of hypothesis and subsequent corroborative inquiry into facts of minute structure and embryological history. Making use of the principle of degeneration, Dohrn started with the legitimate hypothesis that the branches of *Vertebrata* other than *Craniata*—viz., *Cephalochorda*, *Urochorda*, and (though at the time he commenced his work their structure was not fully understood) *Hemichorda*—were not to be regarded as permanent records of steps in the evolution of *Craniata*, but rather as greatly degenerate offshoots from the ancestors of that group, which could throw but little light on the character of their non-degenerate ancestors. A second fundamental assumption which led Dohrn to his position was that the segmentation of the Craniates' body-wall is a primitive and essential feature in their structure, and becomes more and more fully expressed instead of less developed the further we go back in their ancestry. Dohrn, in fact, assumes that what is called metameric segmentation is a phenomenon of structure which has occurred once only in the history of animal form, and that all segmented animals are genetically related and descended from a common segmented ancestor. Assuming this, he pointed to the existing Chætopod Worms as most nearly representing at the present day the common ancestor of segmented animals. They have, as he pointed out, a high organization, little inferior to that of the lowest *Craniata;* they possess a well-developed cœlom, bloodvessels with red blood, a segmental series of nephridia (modified in some as gonaducts), segmental branchiæ, and lateral locomotive organs; not a few develop cartilage as a skeletal support; and many show a concentration and fusion of segments to form a complex head, which resembles, so far, that of *Craniata.* The ventral in place of the dorsal position of the nerve cord led Dohrn to accept De Blainville's conception that the dorsal and ventral surfaces are reversed in *Vertebrata*, as compared with Annelids, Crustaceans, and Insects, so that the Vertebrate is compared to an Insect walking with its ventral surface upward. This led further to the notion that the mouth of the Chætopod or Annelid, which penetrates the nerve-cord, or rather passes between its two divaricated lateral constituents in those animals, has in *Craniata* disappeared, its place being taken by a new mouth derived from the modification of a pair of gill-slits. The remnant of the old mouth, which should, if the comparison instituted holds good, lie in *Craniata* somewhere on the dorsal surface of the cranial region, was sought by Dohrn in some of the peculiar and hitherto unexplained median structures of the brain: at one time the fourth ventricle with its deficient roof was suggested as thus to be explained, whilst subsequently the curious median structures,—the pineal and pituitary bodies,—were called in as possibly thus significant.

Without pursuing further the elaboration of Dohrn's views, it must be at once noted that, whilst the legitimacy of the assumption of degeneration must be admitted, the second assumption, viz., that metameric segmentation is a character bringing all forms showing it into a special genetic continuity, cannot be accepted. The property of repeating units of structure, so as to build up a complex of many similar parts united to form one individual, is a very general one in organic forms, and is exhibited in various conditions by both animals and plants. Its simplest expression is found in cell-structure and the binary division of cells. It shows itself as affecting larger masses of structure in the arborescent colonies of *Cœlentera*, in the radial or antimeric composition of Echinoderms and of Compound Ascidians, and in the linear or metameric segmentation of Worms, Arthropods, and Vertebrates. There is abundant evidence that this property is a general one, which may assert itself at any period in the history of a group of animals, and does not imply special unity of origin in forms which exhibit it. As pointed out in the article Hydrozoa, merogenesis—the name applicable to this phenomenon generally—may take an extreme and complete character, leading to the separation and independence of the units of structure produced; in that case it may be termed eumerogenesis. Or the process may be very partial, occurring only during a period of embryonic growth, and subsequently ceasing, so that later growth obscures or obliterates it altogether (dysmerogenesis). There is no ground for assuming that either one of these extremes is fundamental or original. Any mechanical or nutritional condition may lead to merogenesis in an organism in which the tissues have a certain reproductive capacity, or have not acquired final differentiation; and it will depend upon the balance of advantage, determined by natural selection, whether the segmentation (supposing the merogenesis to take the linear form) results in the separation of segment-buds, or in the formation of an annulate body, or leaves traces of its occurrence only in certain tissues and organs. The Cestoid Worms present within the range of a single group almost every grade of eumerogenesis and dysmerogenesis (*Caryophyllæus*, *Ligula*, *Tænia*). In the otherwise amerogenetic *Mollusca*, Chiton and the pearly Nautilus show dysmerogenesis in certain organs, whilst the Planarian Worms frequently exhibit eumerogenesis in their bud-segmentation (to be compared with that of the Annelid *Ctenodrilus* described by Zeppelin, 9) and the elongated Nemertines only slight traces of dysmerogenesis.

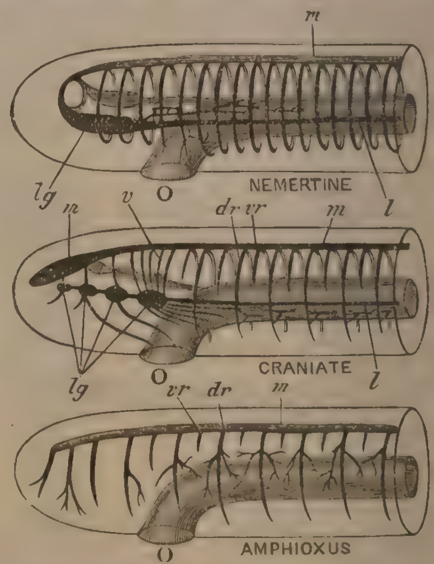

Fig. 6.—Comparison of nervous systems of a Nemertine, a primitive Craniate, and *Amphioxus.* *m*, Median dorsal nerve, which becomes the myelon in the Craniate and *Amphioxus*, acquiring an anterior enlargement in the former; *l*, lateral nerve (right and left), absent by degeneration in *Amphioxus; lg*, ganglia of lateral nerve, forming a single large lobe on each side in the Nemertine, and broken into a metameric series in the Craniate: *v*, roots of vagus nerve of the Craniate; *dr*, dorsal roots of nerves given off from myelon or median dorsal nerve; *vr*, ventral roots of these nerves, here represented as separate nerves; *O*, mouth. (After Hubrecht.)

If we deny Dohrn's assumption with reference to segmentation, we are no longer led in the direction of the Annelids (Chætopods) in our search for the ancestry of the Craniate *Vertebrata.*

The fact that the notochord is the forerunner of the segmented vertebral column, and is itself never segmental, instead of being a difficulty, acquires directive significance. The fact that the nerve tube is dorsal, and not ventral, no longer requires the large assumption that animals have reversed their habitual carriage, but suggests that the Craniates' ancestor had a dorsal median nerve, which has increased in size and importance so as to become the nerve-tube of existing forms. The explanation of the curious structure of the brain will have to be found otherwise than in the assumption of a perforating pharynx,—an assumption which the recent discovery of the true nature of the pineal body has rendered untenable in the latest form advocated by its ingenious author, whose speculations, nevertheless, deserve the fullest recognition as having stimulated inquiry and guided observation.

Balfour (10) in 1878 refused to adopt Dohrn's views, and considered it probable that the dorsal position of the nerve-cord in *Vertebrata* could be accounted for, without any assumption of a substitution of a pair of gill-slits for the original mouth, by assuming that primitively the nerve-cord consisted of two lateral cords, as seen at the present time in the Nemertine Worms, and that these cords have coalesced *dorsally* in *Vertebrata*, just as it is clearly demonstrable that two originally lateral cords have coalesced *ventrally* to form the Annelid's ventral nerve-chain.

The comparison of the Vertebrates' nervous system with that of the Nemertines had already been made by the present writer, as cited by Hubrecht (11) in connection with the latter's discovery of a complete sub-epidermal nerve-tunic in those worms. Hubrecht has more recently on two occasions (12 and 13) developed an interesting and important comparison of Nemertine and Vertebrate structure. He has in the first place suggested that the notochord of *Vertebrata* is nothing more than a modified survival of the proboscidean sheath of the Nemertines, whilst the oral invagination of the epidermis, in connection with the hypophysis cerebri of the Vertebrate, may be a last remnant of the proboscis itself. More conclusively he has drawn attention to the median dorsal nerve of Nemertines as corresponding to the Vertebrate cerebro-spinal nerve cord, whilst the great lateral nerve-cords of Nemertines, and the lateral ganglia in which they expand anteriorly, are compared to the lateral ganglia of the cephalic region of Craniate *Vertebrata* and the nerve of the lateral line (see Fig. 6). The comparison is strengthened by the existence of a metameric series of transverse nerves in the Nemertine, which correspond in respect of their metamerism and their connection with a dorsal median trunk, with the spinal nerves of *Craniata*. Hubrecht is careful to insist that he does not regard the Nemertines as representing the direct ancestry of *Vertebrata;* but he points out that from the primitive condition of an elongate animal, with a plexiform nerve-tunic, it is readily conceivable that a form was developed in which the nervous tissue was concentrated in three cords,—a median dorsal and two lateral,—and from such a form we can derive the Craniates' condition by excessive development of the median tract and relatively small development of the lateral cords, whilst the Nemertines' condition would be attained by the converse process. The tubular condition of the cerebro-spinal nerve-cord of *Vertebrata*, it may here be remarked, is now very generally regarded as being in its origin a purely developmental feature. It was primitively separated from the epidermis by delamination and in-sinking, and the mode of formation by invagination of a canal has been substituted in accordance with a general embryological law of growth, which is that bulky structures originating beneath a surface from the cells forming that surface take up their position in embryonic growth by invagination of the parent surface. The tubular form, having thus started, seems to have been utilized during one phase of Vertebrate evolution for the respiration of the nervous tissue, by the introduction through an anterior unclosed pore of a current of water, which escaped by the neuranal canal (as in larval *Amphioxus*).

There is a wide gap between any form presenting an approach to a Nemertine Worm and the most simple Craniate Vertebrate which can be imagined still provided with the organization characteristic of all *Craniata*. To pass from such a Worm-like animal to a Craniate, we have to account for and introduce, amongst other new developments, (1) a greatly increased metamerism, showing itself in the segmentation of the muscles of the body-wall and in the repetition of the nephridia; (2) the characteristic sense organs; (3) the lateral and median longitudinal folds or continuous fins; (4) the cartilaginous rods and bars of the skeleton; (5) the gill-slits, even if we admit the notochord to be represented by the proboscidean sheath.

It remains to inquire whether the structure of the other

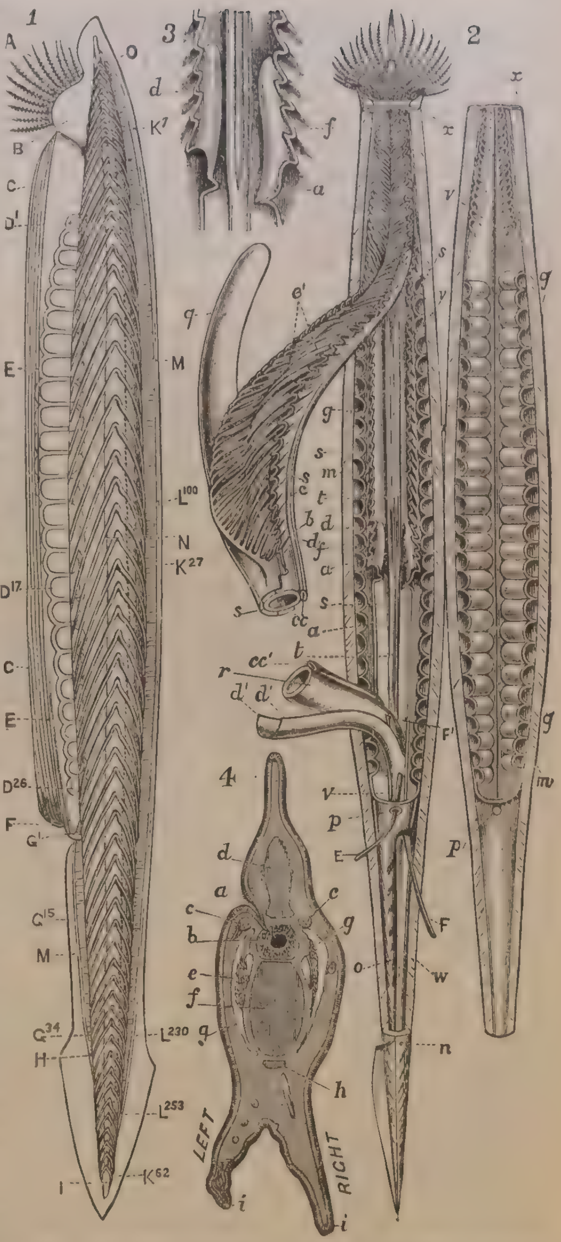

FIG. 7.—*Amphioxus lanceolatus*, Yarrell (*Branchiostoma lubricum*, Coste). (Original drawings.) (1) Lateral view of adult, to show general form, the myomeres, fin rays, and gonads. A, oral tentacles (28 to 32 in full-grown animals, 20 to 24 in half-grown specimens); B, præoral hood or præoral epipleur; C, plicated ventral surface of atrial chamber; D^{1}, D^{17}, D^{26}, gonads, twenty-six pairs, coincident with myotomes 10 to 36; E, metapleur or lateral ridge on atrial epipleur; F, atriopore, coincident with myotome 36; G^{1}, G^{15}, G^{34}, double ventral fin rays, extending from myotomes 37 to 52, but having no numerical relation to them; H, position of anus, between myotomes 51 and 52; I, notochord, projecting beyond myotomes; K^{7}, K^{27}, K^{62}, myotomes or muscular segments of body-wall, 62 in number; L^{100}, L^{230}, L^{258}, dorsal fin rays, about 250 in number, the hard substance of the ray being absent at the extreme ends of the body (these have no constant numerical relation to the myomeres); M, notochord as seen through the transparent myotomes, the thin double-lined spaces being the connective-tissue septa and the broader spaces the muscular tissue of the myotomes; N, position of brown funnel of left side (atrio-cœlomic canal); O, nerve-tube resting on notochord.

(2) Dissection of *Amphioxus*. By a horizontal incision on each side of the body a large ventral area has been separated and turned over, as it were on a hinge, to the animal's left side. The perforated pharyngeal region has then been detached from the adherent epipleura or opercular folds (wall of a trial or branchial chamber) by cutting the fluted pharyngo-pleural membrane *d*, and separated by a vertical cut from the intestinal region. *a*, Edge of groove formed by adhesion of median dorsal surface of alimentary canal to sheath of notochord; *b*, median dorsal surface of alimentary canal; *c*, left dorsal aorta; *cc*, single dorsal aorta, formed by

union of the two anterior vessels; *cc′*, same vessel resting on intestine; *d*, cut edge of pharyngo-pleural folds of atrial tunic, really the original outer body-wall before the downgrowth of epipleura; *d′*, atrial tunic (original body-wall) at non-perforate region, cut and turned back so as to expose peri-enteric cœlom and intestine *r*; *e′*, upstanding folds of body-wall (pharyngo-pleural folds) on alternate bars of perforate region of body; *f*, atrio-cœlomic canals or brown funnels (collar-pores of *Balanoglossus*); *g*, cavity of a gonad-sac; *m*, cut musculature of body-wall; *n*, anus; *o*, post-atrioporal extension of atrial chamber in form of a tubular cæcum; *p*, atriopore; *q*, hepatic cæcum; *r*, intestine; *s*, cœlom; *t*, area of adhesion between alimentary canal and sheath of notochord; *v*, atrial chamber or branchial cavity; *w*, post-atrioporal portion of intestine; *x*, canals of metapleura exposed by cutting; E, probe passing through atriopore into atrial or branchial chamber; FF′, probe passed from cœlom, where it expands behind the atriopore, into narrower perienteric cœlom of præatrioporal region.

(3) Portion of (2) enlarged to show atrio-cœlomic canals ("brown funnels" of Lankester). Lettering as in (2).

(4) Section taken transversely through præoral region near termination of nerve-tube. *a*, Olfactory ciliated pit on animal's left side, its wall confluent with substance of nerve-tube; *b*, pigment spot (rudimentary eye) on anterior termination of nerve-tube; *c*, first pair of nerves in section; *d*, fin ray; *e*, myotome; *f*, notochord; *g*, space round myotome (? artifact or cœlom); *h*, subchordal canal (? bloodvessel); *i*, a symmetrical epipleura of præoral hood.

Vertebrata throws light on this long hypothetical passage from the simple Worm phase to the elaborate Craniate or suggests any other ancestry.

THE CEPHALOCHORDA.

Characters of *Cephalochorda.*

Cephalochorda are *Vertebrata* in which there is no anterior dilatation of the nerve-tube to form a brain (see Fig. 6) and no specialized skeletal brain-case. The notochord extends from one extremity of the elongate body to the other as a tapering unconstricted rod, passing anteriorly some distance in front of the nerve-cord. The longitudinal muscles of the body-wall are divided by transverse fibrous septa into a series of segments (sixty-two in *Amphioxus lanceolatus*), the more anterior of which are in front of the mouth and not in any way fused to form a head or cranial structure. Dense connective tissue (differing but little from cartilage) forms an unsegmented sheath to the notochord and an unbroken neural canal above it, in which the nerve-cord lies. The same tissue forms a series of metamerically repeated fin rays, which support the base of a median fin extending along the entire dorsal surface. The fin is continued ventrally from the caudal extremity as far forward as the anus, but without fin rays. Two lateral out-growths of the body-wall (the epipleura) extend one on either side from the head as far back as the anus. Each of these is divided into three regions,—(1) an anterior, which forms the præoral hood; (2) a median, which forms the wall of the great branchial chamber, the two folds meeting one another and coalescing in the ventral mid-line, excepting where they leave a posterior median aperture, the atriopore; and (3) the post-atrioporal præanal ventral fin (extending between atriopore and anus), which is formed by the complete coalescence of the two folds behind the atriopore. The originally double character of this part of the ventral fin is indicated by the double series of metameric fin rays which support it. It is probable that these "epipleural" folds of *Amphioxus* correspond to the opercular folds and lateral fins of *Craniata*. No cartilaginous fin rays are developed in the atrio-pleural (opercular) region of the epipluera; but a longitudinal unsegmented bar of cartilaginous consistency strengthens its side and bounds a lymph-holding canal (*x* in Fig. 8).

The gill-slits in *Amphioxus* are very numerous (one hundred or more), and have no numerical relation to the metameres of the muscular body-wall, though the first few which appear in the embryo correspond at the time to successive myomeres,—a relation which they subsequently lose. The sides of the gill-slits are supported by chitinous (?) bars, and each slit is divided into two equal portions by a longitudinal tongue or bar, which grows out from the dorsal margin of the slit soon after its first formation. The number of gill-slits increases continually throughout the life of *Amphioxus* by the formation of new ones at the posterior border of the pharynx, whilst the myomeres do not increase in number after early embryonic life.

The nerves given off from the dorsal nerve-cord of *Amphioxus* are of two kinds,—dorsal and ventral. The dorsal nerves correspond in number and position to the myomeres, right and left, except in the most anterior region of the body, where two larger pairs of dorsal nerves are given off from near the extremity of the nerve-cord, and pass forward, supplying the region which lies in front of the termination of the musculature. The ventral nerves are minute, and are given off numerously, right and left, from the nerve-tube throughout its length. The dorsal and ventral nerves of a single myomere appear to correspond, respec-

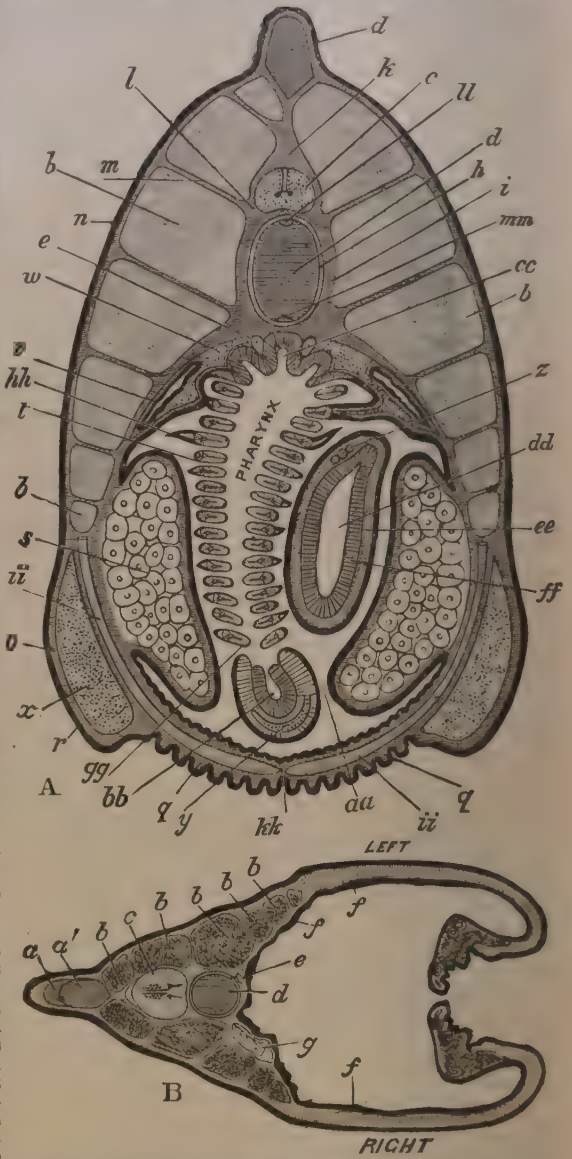

FIG. 8.—Transverse sections of *Amphioxus*. (Original.) A. Section through region of atrio-cœlomic canals. B. Section in front of mouth; the right and left sides are transposed. *a*, Cavity surrounding fin ray; *a′*, fin ray; *b*, muscular tissue of myotome; *c*, nerve-cord; *d*, notochord; *e*, left aorta; *f*, thickened ridges of epithelium of præoral chamber (Rader organ); *g*, coiled tube lying in a cœlomic space on *right* side of præoral hood, apparently an artery; *h*, cuticle of notochord; *i*, connective-tissue sheath of notochord; *k*, median ridge of skeletal canal of nerve-cord; *l*, skeletal canal protecting nerve-cord; *m*, intersegmental skeletal septum of myotome; *n*, subcutaneous skeletal connective tissue; *o*, ditto of metapleur (this should be relatively thicker than it is); *q*, subcutaneous connective tissue of ventral surface of atrial wall (not a canal as supposed by Stieda and others); *r*, epiblastic epithelium; *s*, gonad-sac containing ova; *t*, pharyngeal bar in section, one of the "tongue" bars alternating with the main bars and devoid of pharyngo-pleural fold and cœlom; *w*, so-called "dorsal" cœlom; *x*, lymphatic space or canal of metapleur; *y*, sub-pharyngeal vascular trunk; *z*, blood-vessel (portal vein) on wall of hepatic cæcum; *aa*, space of atrial or branchial chamber; *bb*, ventral groove of pharynx (anteriorly this takes the form of a ridge); *cc*, hyperbranchial groove of pharynx; *dd*, lumen or space of hepatic cæcum; *ee*, narrow cœlomic space surrounding hepatic cæcum; *ff*, lining cell-layer of hepatic cæcum; *gg*, inner face of a pharyngeal bar clothed with hypoblast, the outer face covered with epiblast (represented black); *hh*, a main pharyngeal bar with projecting pharyngeal fold (on which the reference line rests) in section, showing cœlomic space beneath the black epiblast; *ii*, transverse ventral muscle of epipleura; *kk*, raphe or plane of fusion of two down-grown epipleura; *ll*, space and nucleated cells on dorsal face of notochord; *mm* similar space and cells on its ventral face.

tively, to the dorsal and ventral roots of a spinal nerve of a Craniate.

There is a single olfactory pit in *Amphioxus*, which rests upon the left side of the anterior termination of the nerve-cord (see Fig. 7, 4). Within the cavity of the nerve-cord at the same point a patch of brown pigment is present (eye-spot). There are no representatives of the lateral eyes of *Craniata* and no otocysts.

There is no representative of the Craniates' swim-bladder in *Amphioxus*. A single wide diverticulum of the alimentary canal represents the liver of *Craniata;* the pancreas is unrepresented.

The vascular system is singularly incomplete: large trunks exist, but few branches and no heart, whilst the blood itself is colorless, and communicates (as in *Craniata* by the lymphatic "hearts") with the cœlomic fluid at various points. A contractile ventral trunk runs along the lower face of the slit pharynx, and sends vessels right and left up the successive bars; these vessels unite above, as in *Craniata*, to form a double "dorsal aorta," which posteriorly becomes a single vessel. A portal system of veins can be traced in connection with the hepatic cæcum.

No system of lymphatic vessels, nor lymphatic "glands," nor a spleen exist; but the cœlom, and certain other spaces in the connective tissue, contain coagulable lymph, and correspond to the lymph spaces of *Craniata*.

There is no series of nephridia, nor a renal organ formed by the coalescence of nephridia, nor are gonaducts present. The "brown funnels," a pair of funnel-shaped tubes discovered by Lankester (14), place the cœlomic space of the opercular (epipleural) down-growths of the body-wall in communication with the space which these folds enclose. They appear to be identical with the "collar-pores" of *Balanoglossus*, and it is doubtful whether they represent nephridia.

In the larval *Amphioxus* there is developed from the left anterior cœlomic pouch a glandular tube and a sense-organ, which are represented in the adult by the structures marked *f* in Fig. 8, B. Quite distinct from the foregoing is a nephridial tube lying on the left side behind the mouth of the larval *Amphioxus*. This tube is probably the same thing as the subneural gland of Ascidians and as the proboscidean gland and pore of *Balanoglossus*. All are probably of the nature of nephridia. In the adult *Amphioxus* the nephridial tube is in an atrophied condition, though large and active in a *late* larval stage, when the olfactory pit opens into the neural canal. Hatschek (15) describes this condition in "*ausgebildete*" but not in *adult* examples.

The gonads are distinct ovaries and testes; they are developed in distinct male and female individuals in corresponding positions, viz., in that part of the cœlom which is carried downwards in the descending right and left outgrowth (epipleura, opercula) of the body-wall, which encloses the atrial or branchial chamber. The gonads are twenty-six pairs in number, corresponding to the 10-36 myomeres. They are devoid of ducts, and discharge their products by dehiscence into the atrial chamber, whence they pass to the exterior, either by the atriopore or by entering the pharynx through its slits, when they are ejected by the mouth.

Relationship of *Cephalochorda* to *Craniata* and the Vertebrate ancestry.

In many respects *Amphioxus*, the only representative of *Cephalochorda*, bears evidence of being derived from a more highly organized ancestry. Its mode of life (burrowing in the sand in shallow water, whilst its general build is that of a swimming animal) and the nature of its food (diatoms, etc., carried into the pharynx by ciliary currents) in themselves suggest such a history. The vascular system is elaborate in plan yet incomplete in detail, suggesting an atrophy of its finer branches, which is consistent with the small size of *Amphioxus* and the general principle that a complex vascular system can only be developed in an animal which has attained to a certain bulk. The absence of well-developed sense organs and of "cephalization" in an animal which has attained to such elaboration of structure as is shown by the pharynx and atrial chamber, and which has such well-developed muscles to the body-wall, is an inconsistency best explicable by degeneration; so, too, the existence of the elaborate series of fin rays, which are out of proportion to the mechanical requirements of so small a form.

Degenerate though *Amphioxus* must be, the ancestor from which it started on its retrogressive course was probably a long way behind any living Craniate. There is no reason to suppose that this ancestor had a cranium, or that the muscular segments and segmental nerves in its cephalic region were fused and welded. *Amphioxus* has probably lost, as compared with that ancestor, lateral eyes and otocysts, nephridia, and, above all, size. The epipleural folds which now form oral hood, branchial opercula, and coalesced ventral fin were probably originally less developed lateral ridges, protecting the gill-slits anteriorly and posteriorly, serving by their undulations to assist in locomotion, whilst the median fin and its rays were large and functional.

One of the most curious features in the structure of *Amphioxus* is its asymmetry. The anus is on the animal's right side, the nasal pit upon its left; the myomeres on the two sides of the notochord do not coincide; and the right and left dorsal spinal nerves do not arise *vis-à-vis* to one another. There is no conclusive reason for regarding this as an ancestral feature, although the early larval form is as curiously asymmetrical as the adult. *Amphioxus* habitually rests upon the sand, lying upon one side of the body, and it is possible that the distortion is related to this habit, as in the case of the Pleuronectid Fishes.

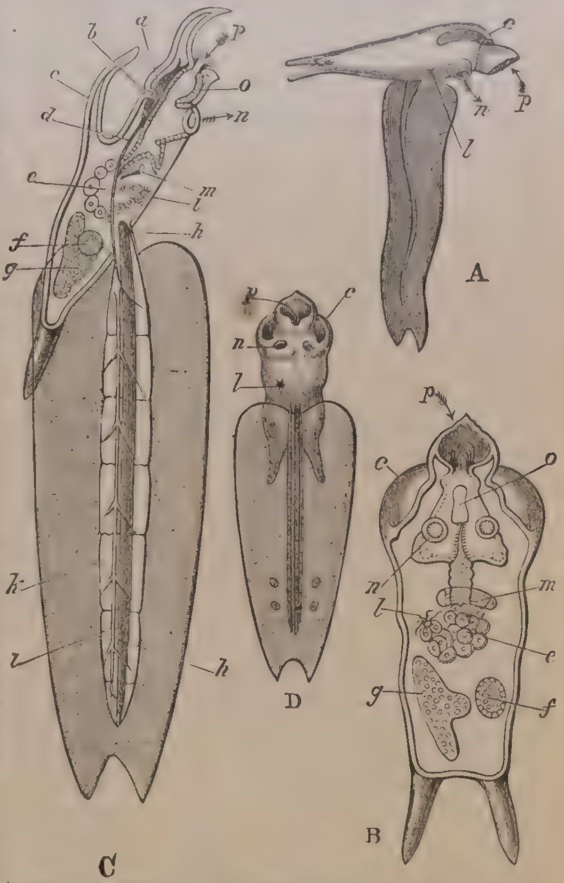

FIG. 9.—*Fritillaria (Appendicularia) furcata*, one of the *Urochorda*. (Original drawings.) A. Lateral surface view, showing habitual carriage of "body" at right angles to "tail." B. Organs of body as seen by transparency. C. Lateral view of the body with tail in morphological position, showing organs by transparency. D. Surface view of animal from below to show apertures. *a*, Otocyst in connection with brain; *b*, olfactory pit; *c*, dorsal hood; *d*, nerve-tube passing from enlarged brain to caudal region, where it forms one true ganglion and a series of minor enlargements, corresponding to the rudimentary "myotomes" or "myomeres" of the tail; *e*, stomach; *f*, ovary; *g*, testis; *h*, notochord (urochord); *i*, nerve-tube or myelon in tail; *k*, fifth myomere of tail; *l*, anus; *m*, heart; *n*, gill-slit; *o*, endostyle or hypobranchial groove; *p*, mouth.

However we may estimate *Amphioxus*, we are not led by it, though its muscular metamerism is so well marked, a single step in the direction of the Annelids, neither are we led directly, it is true, in the direction of *Nemertina* in connection with those points, as to relationship of notochord with proboscis sheath and nerve-chord with median dorsal nerve, insisted on by Hubrecht. But it will be seen below that by the agreement of *Amphioxus* with *Balanoglossus* in the structure of the perforations of the pharynx, in the possession of collar pores, and in the præoral glandular body, we do arrive at an important connection with Nemertine-like forms.

THE UROCHORDA.

Urochorda are *Vertebrata* which, with the exception of the group *Larvalia (Appendicularia, Fritillaria, Oikopleura)*, have receded very far indeed from the characteristic Vertebrate

Characters of *Urochorda.*

structure, showing neither notochord nor nerve-cord and gill-slits only of the most highly modified and aberrant form; some, however (certain Ascidians), pass through a larval condition in which these structures are present in the normal form. It is necessary for the purposes of the present article to confine our attention to *Larvalia* and to the larval forms which retain ancestral characters. (For a description of the whole group, see the article TUNICATA.) In *Urochorda* thus signalized the notochord never reaches forward into the anterior part of the body, but is confined to the tail (hence *Urochorda*). The longitudinal muscles of the region traversed by the notochord show traces of metameric segmentation, which are probably survivals of a more complete development of myomeres in ancestral forms (16). There is no trace in *Larvalia* of fin rays or other skeletal structure. Corresponding to the opercular folds and epipleura of *Craniata* and *Cephalochorda* are ridges of the body wall, which protect the pharyngeal gill-slits, and may give rise, as in *Cephalochorda*, to an enclosed atrial chamber with atriopore. The gill-slits in these larval forms are few in number (one or two pairs), but in many of the aberrant *Urochorda* (by far the majority of the group) they become excessively numerous and complicated in structure, and are supported by a chitinous (?) framework, as in *Cephalochorda*. It has been suggested that the fenestrated structure of the pharyngeal wall in *Tunicata* does not represent a series of gill-slits, but a single pair of slits subdivided. This suggestion is worthy of further consideration.

The cerebro-spinal nerve-cord is tubular and presents itself as a dilated cerebral vesicle in front of the notochord, and as a narrower part running along the whole length of the notochord.

Sense organs are present—a single eye with pigment and lens, a single otocyst, and an olfactory pit (*Larvalia*). The mouth is dorsal in position in the Ascidian tadpole, but subterminal in *Larvalia*. The pharynx is wide, and is followed by a narrow œsophagus, stomach, and intestine, which does not open ventrally but turns upwards to the anus. The *Larvalia* have a rudimentary heart and no vascular system,—a fact connected with their diminutive size. For the same reason no vascular system develops in the Ascidian tadpole until it has ceased to be locomotive and has entered upon its later development; but in the larger adult *Urochorda* a contractile heart and a well-developed vascular system are present.

No undeniable nephridia are present in *Larvalia* nor in the larval Ascidian, and no structure comparable to the collar pores of *Balanoglossus* or the atrio-cœlomic funnels of *Amphioxus* is known in them.

The subneural gland, however, a glandular tube opening anteriorly near the mouth of the pharynx, appears to be identical with the præoral larval gland of *Amphioxus* and the proboscis pore and gland of *Balanoglossus*. It is probably to be regarded as a nephridium, and has been compared by Julin and Van Beneden to the pituitary body of *Craniata*, with which it corresponds in position and development.

The gonads of *Larvalia* are developed in irregular masses on the walls of the cœlom, ovaries and testes in the same individual.

Classification of *Urochorda.*

As above indicated, there is a small section of *Urochorda* which retain in adult life the tadpole-like form and the essential Vertebrate organs which are exhibited by the larvæ only of other *Urochorda*, and by a few only of these. This necessitates a primary division of the branch into two grades.

Grade A.—LARVALIA (*Appendicularia, Fritillaria, Oikopleura*).

Grade B.—SACCATA.

Class I.—*Ascidiæ* (*Simplices, Sociales, Compositæ, Pyrosomiidea*).

Class II.—*Salpiformia* (*Salpiidea, Dolioliidea*).

Relations of *Urochorda* to Vertebrate ancestry.

Urochorda are so extremely aberrant, and show so little more than a transient developmental indication of the essential Vertebrate organs, that we cannot hope to get much positive information from them on the subject of Vertebrate ancestry. Only the minute *Appendicularia* (*Larvalia*) retain the Vertebrate structure through life, and they are obviously, on account of their minute size, extremely degenerate. It is possible to make hypotheses as to the greater or less elaboration of the ancestors of *Urochorda*, and to maintain even that their ancestry had reached as high a condition as that shown by *Craniata*; on the other hand, it does not seem likely that their point of divergence from the main ancestral line leading to *Craniata* was lower than, or even so low as, that at which *Amphioxus* branched off. The differentiation of trunk and tail by the limitation of the notochord anteriorly is a nearer approach to Craniate structure than that shown by *Amphioxus*, whilst the definite development of a brain of considerable relative size places *Urochorda* nearer to the Craniates than is *Amphioxus*. The metameric myomeres so strongly developed in this last are not absent in *Urochorda*, as is often maintained, but exist in a rudimentary form, indicating that they had once a fuller development.

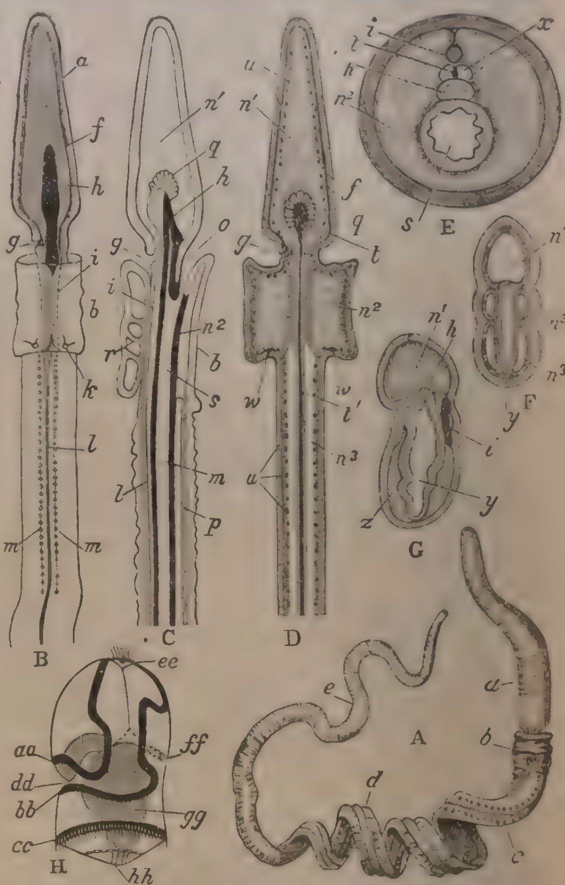

FIG. 10.—*Balanoglossus*, anatomy and development. (Modified from Bateson). A. *Balanoglossus kowalewskii*, Bateson; from the coast of Virginia, U. S.; natural size; *a*, proboscis; *b*, collar; *c*, perforate region; *d*, flattened digestive region; *e*, cylindrical hind region. B. Diagram of dorsal view, showing certain organs as though the body-wall were transparent. C. Diagram of a vertical antero-posterior section. D. Diagram of a dorsal view to show vessels and nerves by transparency. E. Diagram of a transverse section through the collar. F. Larva of *B kowalewskii*; diagram of horizontal section. G. Vertical longitudinal section of an older larva of the same. Lettering B-G: *a*, proboscis; *b*, collar; *f*, nerve-tunic of proboscis; *g*, proboscis pore (ciliated orifice); *h*, notochord (limited to a small tract of modified tissue derived from præoral extension of alimentary canal); *i*, dorsal nerve-plate; *k*, collar-pore (right and left), opening to exterior from collar cœlom just beneath the collar; *l*, continuation of dorsal nerve-plate as a nerve-cord; *m*, pharyngeal perforations (gill-slits); *n′*, cœlom of proboscis (anterior azygos primitive cœlomic pouch); *n²*, collar cœlom (right and left middle cœlomic pouches of embryo); *n³*, body cœlom (right and left posterior cœlomic pouches of embryo); *o*, mouth; *p*, ventral nerve-tunic of body-wall; *q*, proboscis gland; *r*, strands connecting dorsal nerve-plate with outer wall of collar; *s*, cavity of pharynx in front of perforate region; *t*, dilated part (heart) of dorsal vessel within proboscis-gland; *t′*, dorsal vessel; *u*, bloodvessels of body-wall in section; *w*, paired nerves of collar region in transverse section; *x*, perihæmal cœlom, surrounding dorsal vessel in collar region; *y*, digestive region of gut (in embryo); *z*, mesoblast. H. Larva of another species of *Balanoglossus*, known as the *Tornaria* larva of Johann Müller, and resembling an Echinoderm larva. *aa*, præoral ciliated band of *Tornaria*; *bb*, postoral ditto; *cc*, terminal ditto; *dd*, mouth; *ee*, apical plate and sense organ; *ff*, canal system and pore; *gg*, gut; *hh*, anus.

THE HEMICHORDA.

Characters of *Hemichorda.*

Hemichorda comprise the single genus *Balanoglossus*—formerly classified by Gegenbaur as *Enteropneusta*, an independent phylum of the animal kingdom. They are *Vertebrata* of worm-like form, elongate and somewhat flattened from above downwards. In front of the mouth is a long cylindrical proboscis, and behind it a collar, the free margin of which is turned backwards, and corresponds to the opercular epipleural folds of *Cephalochorda* and *Craniata*. This agreement is supported by the existence of a pair of collar pores opening into the cœlom of the collar, as the "brown funnels" of *Amphioxus* open into the epipleural cœlom of that animal. A proboscis pore, opening on the left side into the præoral cœlom of the proboscis (paired in *B. kupfferi*), is exactly representative of the similarly placed pore which in the young *Amphioxus* (according to Hatschek, 15) leads into the tubular organ derived from the left cœlomic chamber of the præoral lobe of that animal. The whole surface of the body is ciliated, as in Nemertines and Echinoderms, and as in no other Vertebrates. Following the collar is a perforated region of the body,—gill-slits opening from the outer surface into the pharynx. In the young form there is for a time, as in *Appendicolariæ* and the Ascidian tadpole, only one pair of gill-slits, but they subsequently increase in number as the animal grows in length. They resemble in form and structure those of *Amphioxus*. The notochord (*h* in Fig. 10) arises at the anterior end of the hypoblast in the young, and grows forward, forming a support for the base of the proboscis. It is limited to this very small region. The cerebro-spinal nerve-cord originates by a delamination of a solid cord of epiblast in the mid-dorsal line of the middle third of the body; then by invagination of its two ends it extends as a tube both anteriorly and posteriorly. A general network of nerve-fibres (and cells?) exists beneath the epidermis all over the body. The blood-system is peculiar, consisting of an anterior heart and a dorsal and ventral vessel; these are united by a plexus of subcutaneous vessels. The musculature of the body-wall is not broken into successive myomeres; but, on the other hand, the gonads (ovaries or testes) are sac-like, and, as in *Amphioxus*, are repeated in a series throughout a great length of the body. In the pharyngeal region the gonad sacs agree in number with the gill-slits. There are no nephridia (unless proboscis pore and collar pores are to be so regarded); but the connective-tissue cells of the body-cavity are active as excreting agents, as in Echinoderms and in *Urochorda*, and a large glandular organ in the proboscis attached to the end of the notochord appears to have to do with this function. Not the least remarkable fact about *Hemichordæ* is the nature of their larvæ. No other *Vertebrata* present larval forms which indicate the nature of the early ancestral history in what we may call præ-chordal times; however interesting the Ascidian larva, or the young *Amphioxus*, and the embryo dog-fish, they do not take us out of the Vertebrate area. Some species of *Balanoglossus* (? *B. minutus*), however, pass through a banded ciliate larval condition, which was known as *Tornaria*, and was considered to be an Echinoderm larva allied to *Bipinnaria*, before its relation to *Balanoglossus* was discovered. It is not possible to view the *Tornaria* larva of *Balanoglossus* as otherwise than identical with Echinoderm larvæ, and it results that *Balanoglossus* and the Echinoderms have remote genetic affinities of a special kind.

Species of *Hemichorda*.

No classification of *Hemichorda* is possible beyond an enumeration of the species:

1. *Balanoglossus clavigerus* (Della Chiaje), Naples.
2. *B. minutus* (Kowalewsky), "
3. *B. kowalewskii* (Al. Agassiz), east coast, United States.
4. *B. brooksii* (Bateson), " "
5. *B. salmoneus* (Giard), Brittany.
6. *P. robinii* (Giard).

Relations of *Hemichorda* to Vertebrate ancestry.

It seems that in *Balanoglossus* we at last find a form which, though no doubt specialized for its burrowing sand-life, and possibly to some extent degenerate, yet has not to any large extent fallen from an ancestral eminence. The ciliated epidermis, the long Worm-like form, and the complete absence of segmentation of the body-muscles lead us to forms like the Nemertines. The great proboscis of *Balanoglossus* may well be compared to the invaginable organ similarly placed in the Nemertines. The collar is the first commencement of a structure destined to assume great importance in *Cephalochorda* and *Craniata*, and perhaps protective of a single gill-slit in *Balanoglossus* before the number of those apertures had been extended. Borrowing, as we may, the nephridia from the Nemertines, and the lateral in addition to the dorsal nerve, we find that *Balanoglossus* gives the most hopeful hypothetical solution of the pedigree of Vertebrates. Space has not permitted us to go so fully into *pros* and *cons* as the speculative nature of the subject requires; but we give the final conclusion to which our consideration of the structure of the four great branches of the *Vertebrata* leads in the form of the accompanying genealogical tree.

VERTUE, GEORGE (1684–1756), engraver and antiquary, was born in St. Martin's-in-the-Fields, London, in 1684. At the age of thirteen he was apprenticed to an heraldic engraver, a Frenchman, who failed in three or four years. Vertue then studied drawing at home, and afterwards worked for seven years as an engraver under Michael Vandergucht. He was patronized by Sir Godfrey Kneller, and was one of the first members of the Academy of Painting which that artist instituted in 1711. His plate of Archbishop Tillotson, after Kneller, commissioned by Lord Somers, established his reputation as an engraver; and he was soon in an excellent practice, engraving portraits after Dahl, Richardson, Jervas and Gibson. In portraiture alone he executed over five hundred plates. In 1717 he was appointed engraver to the Society of

Antiquaries, and his burin was employed upon many interesting statues, tombs, portraits and other subjects of an antiquarian nature. He died on the 24th of July, 1756, and was buried in the cloisters of Westminster Abbey.

From the year 1713 Vertue had been indefatigable in his researches on all matters connected with the history of British art, and had accumulated about forty volumes of memoranda on the subject. These were purchased by Horace Walpole, and form the basis of that author's *Anecdotes of Painting in England*, where will be found an account of Vertue's life and a catalogue of his engravings. Vertue's own literary works include *On Holbein and Gerard's Pictures* (1740); *Medals, Coins, Great Seals, Impressions, from the Elaborate Works of Thomas Simon* (1753); *Catalogue and Description of King Charles the First's Capital Collection of Pictures, Limnings, Statues*, etc., (1757; *Catalogue of the Collection of Pictures belonging to King James II., to which is added a Catalogue of Pictures and Drawings in the Closet of Queen Caroline* (1758); *Catalogue of the Curious Collection of Pictures of George Villiers, Duke of Buckingham* (1758); *Description of the Works of that Ingenious Delineator and engraver, W. Hollar* (1745).

VERUS, M. AURELIUS. See AURELIUS, vol. iii. pp. 75–78.

VERVIERS, a town of Belgium, in the province of Liége, is situated on the Vesdre, 15½ miles by rail east by south from Liége and 19 miles southwest from Aix-la-Chapelle. It is divided into an upper and a lower town, but has no striking architectural features. The staple commodity is cloth, which is manufactured here and in the immediate environs to the value of £3,200,000 [$15,520,000] annually. Other manufactures are soap, chemicals, confectionery, and machinery; dyeing, tanning and iron and copper founding are also carried on. The town is a modern one; its manufacturing prosperity, the beginning of which dates from the 18th century, is partly attributed to the waters of the Vesdre, which are said to be peculiarly well adapted to the purposes of the dyer. The population in 1876 was 37,828.[1]

VESALIUS ANDREAS (1514–1564). See ANATOMY, vol. i. pp. 708–709; also VASCULAR SYSTEM, p. 103 above.

VESICAL DISEASES. The urinary bladder is the temporary reservoir of the renal secretion, and as such contains the urine for longer or shorter periods. In recent years diseases of the bladder have come more than formerly within the scope of operative surgery, owing especially to great advances in the methods of examining the inner walls of the bladder both by sight and touch,—by sight in virtue of the endoscope, an instrument which when introduced into the bladder enables a visual examination of the interior to be made, and by touch, as surgeons do not now hesitate to make incisions into the bladder, either from the perinæum or suprapubically, for purely diagnostic purposes. Further, more careful and improved chemical and microscopical examination of the urine enables the surgeon to judge better than formerly what the condition of the bladder is. Diseases of the bladder may be conveniently divided into two groups,—(1) those which involve recognizable organic structural change, and (2) those which do not necessarily involve obvious organic structural change (Sir H. Thompson). The more important diseases of the first class are inflammation or cystitis, calculi, and neoplastic growths; but there are also others of less importance, such as hypertrophy, dilatation and tuberculosis. The diseases of the second group in which no organic structural change can be recognized in the bladder-wall are numerous. In many cases, however, they can scarcely be considered as diseases of the bladder pure and simple, but rather as concomitants or results of other diseases. Moreover, in many cases they give rise sooner or later to diseases which are accompanied by structural changes. Thus "irritable bladder," although at first it may be independent of any such change, soon gives rise to inflammation of the bladder-wall, or cystitis; and many surgeons describe it from the beginning as simple cystitis, while cystitis as described in this article they call catarrhal cystitis. In this division, however, we may describe paralysis, atony, incontinence of urine, stammering micturition, and retention of urine.

Acute cystitis.

Cystitis.—Inflammation of the bladder may be acute or chronic. It is due in most cases to the presence of irritating matters in the urine, produced by decomposition of the urine itself or by morbid admixture. The inflammation may result also from traumatic injury, from cold, or in cases of gonorrhœa from extension of the inflammation along the urethra into the bladder (through continuity of tissue). Although frequently ushered in by rigors, the chief symptoms of acute inflammation are local: there is pain over the region of the bladder and frequent micturition. The desire to pass water is often incontrollable, even before more than one or two ounces of urine have been secreted. The urine is much changed in its character, being cloudy from the presence of epithelial scales, pus, mucus cells, and often blood. At this stage also it may be ammoniacal, though this usually comes on later, and is probably caused by septic decomposition of the urine due to the entrance or introduction of organisms into the bladder. The quantity of blood varies, but may be so large as to give the urine a distinct reddish tinge. As a rule, the mucous membrane at the neck of the bladder is the first part to become inflamed, but the whole of the mucous membrane may be affected; resolution, however, usually takes place before more than a portion has been attacked.

Chronic cystitis.

Chronic cystitis is one of the most common affections of the bladder, and its causes are very various. It sometimes remains after an acute attack has passed off, but more commonly it results from long-continued irritation, such as may be produced by a urinary calculus in or by atony of the bladder. The symptoms are not so severe as in acute cystitis: the urine contains more mucus, but less pus and blood and there is much less tendency to frequent micturition, the irritability of the bladder being greatly diminished. Frequently very large quantities of mucus are secreted, and the condition is then termed "catarrh of the bladder." Chronic inflammation is not in itself dangerous; but the patient, so long as it remains, is liable to an attack of acute cystitis, which, superadded to the pre-existing condition of the bladder, may be very serious. An increase in the fibrous elements of the coats of the bladder and hypertrophy of the muscular fibres are a common result of chronic cystitis.

Treatment of cystitis.

The treatment in both varieties of the disease consists in giving rest to the inflamed part and in alleviating the pain. Hot sitz-baths may be used two or three times daily for ten minutes or a quarter of an hour at a time; and, if the pain be very severe, hot fomentations with tincture of opium should be applied to the perinæum or hypogastrium, or a hot douche may be used per rectum. Diluent drinks are given, and tincture of hyoscyamus may be prescribed, as it has a very soothing influence. It may be necessary to give morphia, but generally the pain can be allayed without its use. In chronic cystitis the treatment depends very much on the cause, which must if possible be removed. Thus if the cystitis is due to a calculus in the bladder, the treatment is to remove the calculus (see below). Very often, however, special remedies are employed to relieve the inflammatory condition, and one of the best is washing out the bladder. This is a simple operation, based on the principle of siphon action with a head of water, and is carried out as follows. A catheter is introduced through the urethra into the bladder, and to it the stem of a T-shaped tube is fixed: to each end of the horizontal part a piece of rubber tubing is attached, one piece terminating in a vessel which contains an aseptic warm lotion and is placed at a higher level than the bladder, while the other is led into a receptacle placed lower than the bladder. Six or eight ounces of the lotion are allowed to flow into the bladder; then the flow is checked, and the fluid passes out from the bladder through the other tube. Each tube should have a stop-cock, so that the surgeon can open or close it as he desires. Occasionally bladder drainage is resorted to, and is carried out on the principle of siphon action.[2] Internal remedies have to be administered, one of the most valuable being benzoate of soda. The benzoate in its passage through the blood is changed into hippuric acid, and thus tends to render the urine less alkaline. Attention to the diet of the patient is of great importance in both acute and chronic cystitis; it should be very light, easily digested, and nutritious. Diluents are often of much value, lessening the irritability of the bladder. All wines and stimulants should be avoided.

---

[1] [But it was 46,329 in 1887.—AM. ED.]

Calculi.

Calculi.—Important information, as we have already said, is derived both by the surgeon and physician from a careful examination of the urine, whether this be done chemically or microscopically. Not infrequently on such examination crystals, varying in their chemical and physical characters, are found, and if these be in large amount distinct urinary deposits are got from the urine after it has been kept in a vessel for a time. The cause producing these crystals or their presence alone may give rise to disease, as, for instance, oxaluria, a condition in which, in addition to other symptoms, we find oxalate of lime crystals present in the urine. We have here to deal, however, with more than the mere presence of a few crystals disseminated in the urine, viz., with those conditions in which an amalgamation of crystals has occurred, giving rise to a concretion of such deposits into a mass, forming a calculus or stone. When such concretions are so small that they can be passed with the urine through the urethra they are known as *gravel;* but when they are prevented by their size from passing along the urethra they are termed *calculi*, and the patient is said to suffer from stone or calculus. Calculus of the bladder constitutes a most formidable and important disease, and its treatment, either medical or surgical, has probably attracted more attention than that of almost any other disease. Urinary calculi occur in all parts of the world and affect both sexes. They are much more common, however, in some regions than in others. Thus, in India they are very common, while in Great Britain, although many persons suffer from calculus in Norfolk and the north of Scotland, very few cases occur among people who live on the western side of the island. From the above facts many have attributed the formation of calculi to special climatic or geological influences, but it is probable that diet acts as a chief factor in their production. Calculi are much rarer in females than in males, and this may perhaps be explained by the shortness and more vertical position of the urethra, so that the contents of the bladder can be more easily evacuated, and by the fact that the habits of the female with regard to diet are more regular than those of the male. The cause of the formation of a calculus may be (*a*) a tendency in the kidneys to precipitate salts to an abnormal degree, the urine being concentrated and small in amount or (*b*) some abnormal state of the urine in the bladder, or (*c*) the presence of a foreign body in the bladder. Probably the last is the most common cause; for very frequently, when a section of a calculus is made, it is found that some form of foreign body has acted as the nucleus round which urinary deposits have become agglutinated. Such foreign bodies may exist in the bladder or may be introduced from without. Occasionally clots of blood have been found as the nucleus; but one of the commonest is a small uric acid stone, which, having been formed in the kidney, has passed down the ureter into the bladder and there been surrounded by deposits of phosphate of lime, etc. Calculi vary much in their physical characters and chemical constitution. Most frequently only a single stone is present; but very large numbers have been removed from one bladder. The shape of the stone depends on whether it be movable or fixed, and whether there be only one or more in the bladder. A single stone is usually spherical or ovoid, but may be smooth or tuberculated or spinous, this last point being determined chiefly by the composition of the stone; when there are a number of stones present they are usually faceted or many-sided. Some stones are hard; others are soft. In size and weight they vary very much; we find them as small as a pea and as large as a child's head. The largest stone found in the bladder of a human being is in the Royal College of Surgeons museum of England; and in the Edinburgh university surgical museum there is a stone of very large size. The weight depends not only on the size but also on the composition, and varies from a few grains to the heaviest on record, which weighed 6 ℔ 3 oz.

Varieties of calculi.

Seven different kinds of calculi are described, but only three are very common. Vesical calculi are classified according to their composition, and five different forms are very generally recognized; but layers of different salts may be found in the same calculus. (1) The first class embraces *uric acid* and *uratic* calculi. Pure uric acid stones are small and hard, and usually vary in color from a reddish orange to a brown tint. They are frequently rough, but may be smooth. Uratic stones are seldom pure. They frequently form the nucleus of calculi the outer layers of which are phosphatic. (2) *Phosphatic* and *calcareous* calculi consist chiefly of calcium phosphate; stones formed purely of the carbonate of calcium are rare. The stones of this group are white, soft, and friable, especially those composed of phosphate of lime. They frequently attain to a large size, and most commonly occur in persons whose general health has run down to a low ebb. (3) *Oxalate of lime* calculi are excessively hard and dense, of a dark brown color and tuberculated or spinous on their surfaces; hence they are often called mulberry calculi. This is a form which gives rise to great pain and irritation, so that they are generally removed before they become very large. (4) *Cystine* and (5) *xanthin* calculi are rare.

Diagnosing for calculi.

When a stone is present in the bladder, whatever its nature, it acts similarly to any other foreign body, and usually gives rise to a series of definite symptoms. The patient complains of pain in the end of the penis at the completion of micturition. Rough or jolting movements give rise to pain in the region of the bladder. Occasionally there is a sudden stoppage of the flow of urine, which is overcome by a change in position. He suffers from frequency of micturition, just as in any other irritable condition of the bladder. If, in addition to these symptoms, the patient states that at varying intervals he has passed "gravel," the surgeon is almost certain that a calculus is present; but even with all these symptoms there is only one certain diagnostic sign of the presence of a stone, and that is to feel it. This is done by "sounding" the bladder with a sound,—an instrument resembling a bougie but made of steel and with a shorter curve. It can be easily turned from side to side within the bladder, the whole of which must be systematically examined, and not only enables the surgeon to ascertain the presence of a stone but, when judiciously used, assists him in determining the size, mobility, situation, number, and hardness of the calculi. This additional information is of the utmost importance in guiding the surgeon to the best method of treatment. In the child the stone can be occasionally felt by passing one finger into the rectum, laying the other hand above the pubes, and pressing; the stone lies between the two hands. In other cases the size can be gauged with the lithotrite, by observing the distance to which the blades are separated when the stone is grasped.

Treatment.

The treatment of calculi by other means than operative surgery has been found to be of very little value. Attempts have been made to dissolve calculi by internal remedies or by the injection of chemical agents into the bladder; but, although many such methods have been used, and have for a time in many cases been apparently successful, they have without exception been found in the long run to be practically worthless for removing calculi once actually formed. Further, the improvements in operative means for the removal of calculi have advanced to such a degree that it is probably better for a patient, in our present state of knowledge, to be treated by some one of them rather than undergo any attempt at their removal by other means. Nevertheless much can be done towards preventing the formation of calculi in those who have a tendency to their formation, by attention to diet and by the internal administration of drugs.

Removal of calculi by operation.

Urinary calculi are removed by one of three methods,—(i.) lithotomy or cutting for stone, (ii.) lithotrity, or crushing the stone, and (iii.) litholapaxy, a modification of lithotrity and the method now most commonly adopted. In about nine cases out of evey ten the stone may be crushed; but occasionally there are some circumstances which render the operation of lithotomy preferable to lithotrity. Thus, where the urethra is constricted, as in organic stricture or enlarged prostate, or where the stone is very large or extremely hard, it is right to cut for the stone instead of making any attempt to crush it. Again, in children, lithotomy is safer than lithotrity.

Lithotomy.

Lithotomy.—Cutting for stone has been very long known and practiced by surgeons; but up to the commencement of the 19th century it was performed only by a few men, who, bolder than their contemporaries, had specially worked at it and had attained celebrity as skilful lithotomists. Patients went very long distances to be operated on by them. And certain of the older surgeons, as Cheselden, performed a large number of operations with very successful results. The operation is usually performed by an incision from the perinæum; but sometimes it is necessary to adopt the high or suprapubic incision. The former method is termed *perineal* lithotomy, and, as the incision most commonly made by the surgeon is a lateral one, it is ordinarily spoken of as *lateral* lithotomy. Lateral lithotomy consists of two distinct stages, —(i.) cutting into the bladder and (ii.) removing the stone. The patient is placed on a table and brought under the influence of an anæsthetic. A grooved staff is passed along the urethra into the bladder to act as a guide for the knife, and the patient is then "tied up in the lithotomy position." An assistant holds the staff in the middle line of the body and the surgeon makes an incision an inch and a half in length deeply into the perinæum, until the knife enters the groove of the staff, and then passes it along the groove, thus making an opening through the bladder-wall. The bladder having been thus cut into, a pair of lithotomy forceps is introduced by the perineal wound, and the stone is caught and removed by gently withdrawing the forceps by a rotatory movement. A lithotomy tube is now passed through the wound into the bladder and fixed in position; the patient is untied and carried back to bed. The operation of lithotomy is not a difficult one to perform, nor is it in itself dangerous; sometimes, however, there is a fatal termination, due commonly to one or other of the following causes—hæmorrhage (either primary or secondary), organic disease of the urinary organs, or blood poisoning. Hæmorrhage may be the result of unskilful operating, the incision having been incorrectly made; or one of the larger vessels in this neighborhood may have had an abnormal distribution, so that, lying in the line of the incision, it was divided and gave rise to the bleeding which proved fatal. If the stone be a very large one, or the perinæum very narrow, it is necessary to perform the suprapubic operation.

Litholapaxy.

Litholapaxy.—Lithotrity too can be best described if considered under two headings,—(i.) the crushing of the stone and (ii.) the removal of the detritus. The two stages are now carried out at "one sitting," instead of allowing an interval to elapse between them, as was formerly the practice, and the term *litholapaxy* is used to designate this method. The patient having been anæsthetized, the urethra is dilated by the passage of large-sized bougies. Then a few ounces of a warm neutral aseptic fluid are injected into the bladder, and the crushing instrument, the lithotrite, is passed along the urethra into the bladder. The lithotrite has two blades, —a "male" and a "female,"—the latter fenestrated, the former solid with its surface notched; these blades can be approximated both by a sliding and a screwing movement. The sliding movement is used to grasp the stone; but when the stone is fixed between the blades the screw action is used, as it enables great pressure to be applied evenly, gradually, and continuously. The lithotrite is made of very tough steel, so that even very hard stones may be crushed without any danger of the instrument breaking. It is passed into the bladder with its blades closed; they are then opened and an attempt made to grasp the stone. The stone having been fixed between the blades by the sliding movement, it is then crushed with the screw action, great care being taken not to catch the bladder-wall with the lithotrite. This danger is avoided by raising the point of the lithotrite immediately after grasping the stone and before crushing is begun. The stone breaks into two or more pieces, and these fragments must next be caught and crushed one by one, until they are all reduced to a very small size. If the stone be large and hard, half an hour or longer may be required to crush it sufficiently. When the surgeon fails to catch any more large portions of stone, the presumption is that it has been broken up into small enough pieces; the lithotrite is then withdrawn and the second stage of the operation must be begun. This consists in removing the detritus by means of an aspirator, the best form of which is that invented and used by Sir Henry Thompson. It consists of an elastic bag connected with a trap, into which fragments of stone will fall and not pass out again on the instrument being used at later periods in the operation. A large catheter, with the eye very near the distal end of the short curve, is passed into the bladder; the aspirator, full of an aseptic fluid, is attached to the catheter, and a few ounces of the fluid are expressed from the aspirator into the bladder by squeezing the india-rubber bag. When the pressure is taken off the bag, it dilates and draws by suction the fluid out of the bladder, and with it some of the detritus of the crushed stone, which falls into the trap, and is not expelled on the fluid being re-introduced into the bladder. This manœuvre is repeated again and again, until all the fragments and detritus of the stone have been removed. After the operation the patient sometimes suffers from pain and discomfort; but these are not at all severe unless some fragments have been left in the bladder. If the pain be severe, it can very generally be relieved by hot fomentations or a sitz-bath. The patient must be kept in bed for some days after the operation, and in cases where the stone has been large and the bladder irritable the surgeon should insist on him remaining in bed for at least a week. Judging by statistics, the dangers of the operation, if it be gone about with care, are not nearly so great as those of lithotomy, and certainly in those cases which go on favorably the patients are much sooner able to perform their ordinary duties. Fatal terminations, however, do now and again occur, sometimes as a result of injury to the bladder-wall setting up inflammation, which extends to the kidneys, sometimes from suppression of urine. Those cases in which there has been a fatal result most frequently have been complicated with old-standing kidney disease.

Neoplastic growths.

Neoplastic Growths.—The commonest neoplasms found in the bladder are vascular fibromata (often called villous cancers) and epitheliomata; more rarely malignant growths occur. The symptoms produced by tumors vary; but they may cause obstruction to the flow of urine and chronic cystitis, with more or less severe pain. The most important signs are the passage of blood and the presence of tumor cells in the urine. Frequently, however, microscopical examination of the urine fails to discover the presence of tumor cells. The passage of blood may be very intermittent and small in amount; but this intermittent bleeding is one of the most characteristic signs of the existence of a tumor. When the presence of a tumor is suspected, the sound is passed and an attempt made to feel it. Sometimes it can be felt, but more often doubt remains as to whether a tumor does really exist or not. In such cases the endoscope may be had recourse to; but the information derived from its use is not always satisfactory, and a diagnostic incision must then be made into the bladder to verify the diagnosis. When such a diagnostic incision is made, the surgeon must be prepared to remove the tumor, should one be present and capable of removal. Usually the diagnostic incision is perineal; but, if the bladder is capacious, or if the perinæum is deep and narrow, a more complete examination can be made by a suprapubic opening. The treatment of neoplasms is, as a rule, unsatisfactory. If the growth be pedunculated, it can be removed without great risk to the patient; more commonly, however, the tumor cannot be removed, and then only palliative measures can be adopted, such as allaying the pain and checking the hæmorrhage. Great relief is often given by washing out the bladder; but this must be done with very great care, a soft flexible catheter being used, if it can be passed into the bladder, in preference to a rigid one.

Hypertrophy and dilatation.

Hypertrophy and Dilatation.—When there is long continued obstruction to the flow of urine, as in stricture of the urethra, enlarged prostate, etc., the bladder-wall becomes much thickened, the muscular fibres increasing both in size and number; the interstitial fibrous tissue is also increased. The wall on its inner surface becomes rugose, and the condition is technically known as *hypertrophy*. Hypertrophy may be accompanied by *dilatation* of the bladder, a condition which the bladder may assume when from any cause the evacuation of its contents is interfered with for a length of time.

Paralysis of bladder.

Paralysis of the bladder is a want of contractile power in the muscular fibres of the bladder-wall. It may result from injuries whereby the spinal cord is lacerated or pressed upon at or below the micturitory centre situated in the lumbar region. The result may be either retention or incontinence of urine; sometimes there is at first retention, which later on is followed by incontinence, while in other cases incontinence results in the first place and then retention. Paralysis is also produced in certain nervous diseases, as in locomotor ataxia, and in various cerebral lesions, as in apoplexy.

Atony of bladder.

Atony of the bladder differs from paralysis in being only a paresis or partial paralysis. It is due to a want of tone in the muscular fibres, and is most frequently the result of habitual overdistension of the bladder, such as may occur in cases of enlargement of the prostate. The patient is unable to empty the bladder, and the condition of atony gets increasingly worse.

In both paralysis and atony the indication is to carefully prevent over-distension of the bladder by the urine being retained too long, and at the same time to treat by appropriate means the cause which has produced or is keeping up the condition.

Incontinence of urine.

Incontinence of urine may occur in the adult or in the child, but is due to widely different causes in the two cases. In the child it may be simply a bad habit, the child not having been properly trained; but more frequently there seems to be a want of control in the micturitory centre, so that the child passes its water unwittingly, especially during the night. In adults it is not so much a condition of incontinence in the sense of water being passed against the will, but is rather due to a difficulty in retaining the urine in consequence generally of an over-full bladder,—the water which passes being the overflow from a too full reservoir. It is usually caused by an obstruction external to the bladder, *e.g.*, enlarged prostate or stricture of the urethra. Occasionally the presence of a calculus may produce the condition. The treatment differs in the case of the child and of the adult. In the child an attempt must be made to improve the tone of the micturitory centre by the use of belladonna or strychnia internally and of a blister or faradism externally over the lumbar region, and every effort should be made to train the child to pass its water at stated times and regular intervals. In the adult the cause which produces the overdistension must be removed if possible; but as a rule the patient has to be provided with a catheter, which he can pass into his bladder and thus thoroughly empty it before it has filled to overflowing. A soft flexible catheter should be given in preference to a rigid or semi-rigid one. The best form is the red-rubber catheter.

Stammering micturition.

The condition termed by Sir James Paget *stammering micturition* is frequently seen in young men, more rarely in children and adults. This stammering of the urinary apparatus is analogous to speech stammering, and occurs chiefly in those who are nervous and easily put out. It would seem to be due to incoordination of the sphincter and detrusor of the bladder, the former not relaxing synchronously with the contraction of the detrusor, or *vice versa* and is sometimes caused by external irritation, such as preputial adhesions. Occasionally not a drop of urine can be passed, or a little passes and then a sudden stoppage of the flow occurs, and the more the patient strains the worse he becomes, until at last there is complete retention of urine. Very usually such errors in micturition can be cured by the removal of irritating causes, if they exist, and in these cases, as well as in those in which no such cause can be discovered, great care should be taken to avoid those difficulties which have given rise to the patient's worst failures. If at any time he should fail to perform the act of micturition, he ought not to strain, but should quietly wait for a little before making any further effort, after which he will often succeed. Regularity in the times of making water is also of much importance.

Retention of urine.

Retention of urine cannot be called a disease of the bladder, but may be the cause of, or result from, bladder disease. It may occur in paralysis of the bladder, or in conditions where the patient is suffering from an illness which blunts the nervous sensibility, *e.g.*, typhoid fever. It is, however, much more commonly due to obstruction in some part of the urinary passage anterior to the bladder, as in stricture of the urethra or enlargement of the prostate. The patient can usually tell when he last passed any urine; but, even when no such information can be obtained, there are signs which lead the surgeon to a correct diagnosis. Thus, the bladder if much distended can be felt as a rounded swelling above the pubes, and it may even have passed to the level of the umbilicus. Percussion of the hypogastrium gives a dull note. When retention of urine occurs and the bladder is over-distended, it is necessary to evacuate its contents as soon as possible. If there is no obstruction to the flow of urine, the retention being due merely to atony or paralysis of the bladder, a flexible soft catheter is passed into the bladder and the water drawn off. But when there is an obstruction which cannot be overcome, aspiration of the bladder has to be resorted to, the needle of the aspirator being pushed through the abdominal wall into the bladder. The point of puncture in the abdominal wall is in the middle line just above the symphysis pubis. The bladder has been aspirated in this way very many times in the same person without any evil result. But in all cases strict antiseptic precautions must be adopted. (J. C.)

VESOUL, a town of France, chef-lieu of the department of Haute-Saône, is situated 147 miles southeast of Paris by the railway to Mülhausen, at the junction of branch lines to Gray and Besançon, on the river Durgeon, which here receives two tributaries. The isolated conical hill of La Motte (1483 feet), which shelters the town on the north, affords fine views of the Jura and the Vosges Mountains. On the summit is a votive chapel (1854). The chief features of Vesoul are the palace of justice, the church of St. George with a fine altar, the promenade with a monument to the gardes mobiles of the department who fell at Belfort in 1870 and 1871, a library of 20,000 volumes, and an archæological museum. The population in 1881 was 9431 (commune 9553), the corresponding figures for 1886 being 9602 and 9733.

Vesoul, which is first mentioned in the 10th century, was originally a fief of the church of Besançon. It afterwards passed to the house of Burgundy, and was fortified. The castle was destroyed in the 17th century. The town suffered much during the Wars of Religion and the Thirty Years' War. Vesoul belonged temporarily to France after the death of Charles the Bold, was returned to the empire when Charles VIII. broke off his marriage with the daughter of the emperor Maximilian, and again became part of France under Louis XIV. after the peace of Nimeguen.

VESPASIAN. TITUS FLAVIUS VESPASIANUS, the tenth of the twelve Cæsars, was Roman emperor from 70 to 79 in succession to Vitellius. He was born in the year 9, and in the Sabine country near Reate. His father was a tax-collector and money-lender on a small scale; his mother, however, was a lady of pretty good family, with a brother a senator. She encouraged her son to look up in the world. After having served with the army in Thrace and been a quæstor in Crete and Cyrene, Vespasian rose to be ædile and prætor, having meanwhile taken to wife the daughter of a Roman knight, Flavia Domitilla, by whom he had two sons, Titus and Domitian, both of whom succeeded him. Having already served in Germany, in the years 43 and 44, in the reign of Claudius, he had the command of a legion in Britain under Aulus Plautius, and saw much hard fighting, reducing to subjection the Isle of Wight and penetrating very possibly into Devonshire and the neighborhood of Exeter. He proved himself a thoroughly able soldier, while in his habits he was simple and frugal; in short, says Tacitus (*Hist.*, ii. 5), "but for his avarice he was equal to the generals of old days." In 51 he was for a brief space consul; soon afterwards he went as governor to Africa, where according to Tacitus (ii. 97), his rule "was infamous and odious," according to Suetonius (*Vesp.*, 4), "upright and highly honorable," though he admits that there was a serious local disturbance in which the governor was pelted with turnips. On leaving Africa there was a story (Suet., *Vesp.*, 4), that he got his livelihood as a dealer of some sort,[1] which, if true, shows that he did not turn his provincial governorship to profit. He went with Nero's suite to Greece, and in 67 was appointed to conduct the war in Judæa, which was threatening general commotion throughout the East, owing to a widely spread notion in those parts that from Judæa were to come the future rulers of the world. Vespasian, who had a strong vein of superstition, was made to believe that he was himself to fulfil this expectation, and all manner of omens and oracles and portents were applied to him. He also found encouragement in Mucianus, the governor of Syria; and he had a soldiery thoroughly devoted to him, although he was at the same time a strict disciplinarian and reformer of abuses. Vespasian had, however, plenty of practical good sense, and he knew well how to strike down a foe. All eyes in the East were now upon him; Mucianus and the Syrian legions were eager to back him up; and on the 1st July, 69, while he was at Cæsarea, he was proclaimed emperor, first by the army in Egypt, and then by his troops in Judæa. The legions of the East at once swore to him the customary oath of allegiance. Nevertheless Vitellius had on his side the veteran legions of Gaul and Germany, Rome's best troops. But the feeling in Vespasian's favor quickly gathered strength, and the armies of Mœsia, Pannonia, and Illyricum soon declared for him, and made him in fact master of half of the Roman world. They entered Italy on the northeast under the leadership of Antonius Primus, defeated the army of Vitellius at Bedriacum, sacked Cremona, and advanced on Rome, which they entered after furious fighting and a frightful confusion, in which the Capitol was destroyed by fire. The new emperor received the tidings of his rival's defeat and death at Alexandria, whence he at once forwarded supplies of corn to Rome, which were urgently needed, along with an edict or a declaration of

[1] *Ad mangonicos quæstus descenderat.*

policy, in which he gave assurance of an entire reversal of the laws of Nero, especially those relating to treason. While in Egypt he became more and more imbued with superstition, consulting astrologers and allowing himself to be flattered into a belief that he possessed a divine power which could work miracles. Leaving the war in Judæa to his son Titus, he arrived at Rome in 70, where he restored the Capitol, rebuilt a great part of the city, enforced discipline in the army, which under Vitellius had become utterly demoralized, and with the co-operation of the senate put the government and the finances on a sound footing. By his own example of simplicity of life, he put to shame the luxury and extravagance of the Roman nobles and initiated in many respects a marked improvement in the general tone of society. As censor he raised the character of the senate, removing unfit and unworthy members, and promoting good and able men, among them the excellent Julius Agricola. In 70 a formidable rising in Gaul, headed by Claudius Civilis, was suppressed; the Jewish War was brought to a close by Titus's capture of Jerusalem, and in the following year, after the joint triumph of Vespasian and Titus, memorable as the first occasion on which a father and his son were thus associated together, the temple of Janus was closed, and the Roman world had rest for the remaining nine years of Vespasian's reign. The peace of Vespasian passed into a proverbial phrase. In 78 Agricola went to Britain, and both extended and consolidated the Roman dominion in that province, pushing his arms into North Wales and the Isle of Anglesey. In the following year Vespasian died, in his 70th year.

The avarice with which both Tacitus (*Hist.*, ii. 5) and Suetonius (*Vesp.*, 16) stigmatize Vespasian seems really to have been an enlightened economy, which, in the disordered state of the Roman finances, was an absolute necessity. Vespasian could be liberal to impoverished senators and knights, to cities and towns desolated by natural calamity, and especially to men of letters and of the professor class, several of whom he pensioned with salaries of as much as £800 ($3888) a year. Quintilian is said to have been the first public teacher who enjoyed this imperial favor. Vespasian may be fairly credited with doing his best to improve and elevate the tone of the age by spreading those intellectual tastes with which personally he was not much in sympathy. Pliny's great work, the *Natural History*, was written during Vespasian's reign, and dedicated to his son Titus, who almost shared the emperor's throne (see TITUS). Some of the philosophers, pedants in reality, who talked idly of the good old times of the republic, and thus indirectly encouraged conspiracy, provoked him into reviving the obsolete penal laws against this class, but only one, Helvidius Priscus, was put to death, and he had affronted the emperor by studied insults. "I will not kill a dog that barks at me" were words honestly expressing the temper of Vespasian. Much was spent on public works and the restoring and beautifying of Rome during his reign,—a new forum, the splendid temple of Peace (symbolizing the sentiment of the age), the public baths, and the vast Colosseum being begun under Vespasian.

To the last Vespasian was a plain, blunt soldier, with decided strength of character and ability, and with a steady purpose to establish good order and secure the prosperity and welfare of his subjects. In his habits he was punctual and regular, transacting his business early in the morning, and enjoying his siesta after a drive. He had not quite the distinguished bearing looked for in an emperor. He was free in his conversation, and his humor, of which he had a good deal, was apt to take the form of rather coarse jokes. He could jest, it was said, even in his last moments. "Methinks I am becoming a god," he whispered to those around him. There is something very characteristic in the exclamation he is said to have uttered in his last illness, "An emperor ought to die standing."

The *Histories* of Tacitus and the biography of Suetonius are our chief original sources about Vespasian. Dean Merivale, in his *History of the Romans under the Empire*, gives a very complete account of him (chaps. 57, 59, 60).

VESPERS (*Officium vespertinum*) in the Roman Catholic liturgy is that part of the daily office which follows none (*nona*) and precedes compline (*completorium*). In it the Pater Noster, Ave Maria, Deus in Adjutorium, etc., are followed by five psalms and five antiphons, after which come the "little chapter," the hymn and the verse, which vary according to the season, the Magnificat and its antiphon, and the appropriate collect. In its general features the use of this office can be traced back to a very early date both in the Eastern and in the Western Church. Vespers may be said or sung at any time after midday, and in some circumstances even before it.

VESPUCCI, AMERIGO (1451–1512), navigator, was born at Florence on 9th March, 1451. His father, Nastugio Vespucci, was a notary, and his uncle, to whom he owed his education, was a scholarly Dominican and a friend of Savonarola. As a student Amerigo showed a preference for natural philosophy, astronomy and geography. He was placed as a clerk in the great commercial house of the Medici, then the ruling family in Florence. About 1490 he was sent by Lorenzo de' Medici to Spain, and in January, 1492, he was at Cadiz, along with an associate, Donato Nicolini, probably as an agent of the Medici. Shortly after this he seems to have entered the service of a Florentine merchant, Juonato Berardi, established at Seville, who had fitted out the second expedition of Columbus in 1493. Berardi had also undertaken to fit out twelve ships for the king of Spain, and on his death in December, 1495, Vespucci was commissioned to complete the contract. There is no proof that Vespucci accompanied Columbus on either his first or his second voyage, though there can be no doubt that the two Italians were known to each other. As Ferdinand had recalled the monopoly conceded to Columbus, the new passion for exploring became widespread and adventurers of all kinds were constantly leaving Spain for the West. On the authority of Vespucci himself, he sailed, possibly as astronomer, with one of these adventurous expeditions from Cadiz, on 10th May, 1497. After touching at the Canaries, the four vessels are stated to have reached after twenty-seven days "a coast which we thought to be that of a continent"; from Vespucci's account this may have been Campeachy Bay. Thence they doubled Cape Sable and may even have reached Cape Hatteras. Finally, after sailing about a hundred leagues to an archipelago, the chief island of which was called Iti, they made for Spain and reached Cadiz on 15th October, 1498. Still following Vespucci's own statement, he, on 16th May, 1499, started on a second voyage in a fleet of three ships under Alonzo de Ojeda. They reached the coast of Brazil about Cape St. Roque, sailed north to the mouth of the Amazons, round to the Gulf of Maracaibo, and on to San Domingo. The expedition returned to Cadiz on 8th September, 1500. Entering the service of Dom Manual of Portugal, Vespucci took part in a new expedition to the "Land of Parrots" (Brazil), which left Lisbon on 10th May, 1501. Cape St. Roque was reached on 16th August; Rio Janeiro Bay was discovered and named on New Year's Day, 1502; and in April the expedition appears to have got as far as South Georgia. It reached Lisbon again on 7th September, 1502. Next year, on 10th June, Vespucci started from Lisbon on his fourth expedition, with six ships under Coelho, the object being to reach Malacca by sailing west. At the island of Fernando Noronha Vespucci's ship separated from the others and sailed to Bahia and then to Cape Frio, where he built a fort. He returned to Lisbon on 18th June, 1504. In 1505 he went back to Spain and re-entered the service of Ferdinand, settling in Seville. According to one account, Vespucci made two other voyages to the isthmus of Panama. In 1508 he was appointed *piloto mayor*. He died at Seville on 22d February, 1512.

If his own account is trustworthy, Vespucci reached the mainland of America eighteen days before Cabot. Yet he was attached to the expedition only in a subordinate capacity, and, had it not been that his name has become attached to the New World, it is probable he would scarcely have been heard of. It seems to be credible, however, that in a letter written soon after his return from his third voyage he referred to the newly discovered lands as the "New World." Vespucci's claim to have touched the American mainland before Cabot has been hotly disputed, and the controversial literature on the subject is voluminous. The facts, as accepted by those who admit his claims, or at least his good faith, are these: After his fourth voyage, that is after 1504, he wrote a diary called *Le Quattre Giornale.* No fragment of the original exists, and it is only known by allusion. He also wrote several letters to his former schoolfellow Soderini, the gonfalier or chief magistrate of Florence. One of these only remains, and that not in the original, but in a Latin translation printed at the monastery of St. Dié in the Vosges on 25th April, 1507. The statement is that a French translation of Vespucci's original had been given to King René, who was patronizing the college at St. Dié. Waldseemüller (Hylacomylus) made use of this letter in his *Cosmographiæ Introductio*, published at St. Dié in 1507. Here it is that we have the first suggestion of a name for the New World in the words, "A fourth part of the world, which, since Amerigo found it, we may call Amerigé or America"; and again, "now a fourth part has been found by Amerigo Vespucci, and I do not see why we should be prevented from calling it *Amerigé* or *America.*"[1] Since Humboldt discussed the subject in his *Examen Critique de l' Histoire de la Géographie du Nouveau Continent,* vol. iv. (1837), the general weight of opinion has been that Vespucci did not make the 1497 voyage, and that he had no share in the first discovery of the American continent, but that there is not sufficient evidence to convict him of deliberate falsification. Varnhagen, however, in his *Amerigo Vespucci* (Lima, 1845) and many other writers on the subject maintain Vespucci's right to be regarded as a member of the expedition.

The whole question is very thoroughly discussed in vol. ii. of the *Narrative and Critical History of America*, edited by Justin Winsor (1886), where will be found ample references to all the authorities on the subject. See also Major's *Prince Henry the Navigator* (1868), and a recent re-examination of the evidence for the first voyage in "Alcune Corsiderazioni sul Primo Viaggio," by L. Hugues, in the *Bolletino* of the Italian Geographical Society, 1885.

VESTA (Greek *ϝεστία*), the goddess of fire and the domestic hearth. The cults of the Greek Hestia and the Latin Vesta, both of which involved the guardianship of an ever-burning sacred fire, are most probably derived from a very early custom, common to a great variety of races, and practiced during many different ages. Among people in a primitive state of development the production of fire is a slow and very laborious process; thus it became the custom for each village to maintain a constant fire for the general use of the community, in order to avoid the troublesome necessity of obtaining a spark by friction in case of the accidental extinction at one time of all the village fires.[2] This fire, the central hearth or *ϝεστία* of the village (*focus publicus*), became a sacred symbol of home and family life, and by degrees grew into a religious cult of great sanctity and importance. The form of the primitive house in which the fire was preserved, probably a round hut made of wattled osiers daubed with clay, appears to have survived both in the circular prytaneum of the Greeks and in the Ædes Vestæ in Rome. To watch this fire would naturally be the duty of women, and especially of those who were not burdened with the cares of maternity, and hence may have arisen the Roman order of virgin priestesses, whose chief duty it was to tend the sacred fire. A survival of the prehistoric method of getting a spark appears to have existed in the rule which enacted that, if ever the sacred fire of Vesta did go out, the negligent vestal was to be punished by scourging (Livy, xxviii. 11), and the fire rekindled either by friction of dry sticks[3] or, in later times, by the sun's rays brought to a focus by a concave mirror (Plut., *Numa*, 9). In the prytaneum, which existed in every Greek state, a different form of cult was developed, though the essential point, the sacred fire, was kept up, just as in the Latin worship of Vesta; and in both cases the fire was extinguished annually at the beginning of the new year, and solemnly rekindled by one of the primitive and hence sacred methods.[4] In Rome this was done on the first day of March, the Latin New Year's Day (Ovid, *Fast.*, iii. 137–145). Both among Greek and early Latin races, at the founding of a new colony fire was solemnly sent from the prytaneum or Vesta temple of the mother colony to kindle a similar sacred fire in the new settlement. Thus we find that, according to tradition, the worship of Vesta in Rome was introduced from Alba Longa (Liv., i. 20, and Ov., *Fast.*, iii. 46), which appears to have been the oldest of the Latin colonies in Latium. This intimate connection between the Greek prytaneum fire, sacred to Hestia, and that of Vesta in Rome has been ably worked out by Mr. J. G. Frazer in the paper quoted above. The most generally received Latin legend attributes the founding of the Roman temple of Vesta to Numa, who transferred the centre of the cult from Alba, together with the four vestal virgins, its priestesses (Plut., *Numa*, 10). One of the later kings, either Tarquin I. or Servius Tullius, is said to have increased the number to six (Dion. Hal., iii. 67, and Plut., *Numa*, 10), and it is not till the last years of the pagan period that we hear of a seventh vestal having been added (see Ambrose, *Epis.*, ed. Pareus, p. 477; also Plut., *Rom.* and *Cam.*).

The election (*captio*) of the vestal during the early period of Rome was in the hands of the king, and in those of the pontifex maximus under the republic and empire,[5] subject, however, to the following conditions (Aul. Gell., i. 12): (1) the candidate was to be more than six and less than ten years of age; (2) she was to be *patrima* and *matrima*, *i.e.*, having both parents alive; (3) free from physical or mental defects; (4) daughter of a free-born resident in Italy. Certain details of the election were arranged subject to the provisions of the Lex Papia, now unknown. The selected child had her hair cut off, and was solemnly admitted by the pontifex maximus, who held her by the hand, and, addressing her by the name *amata*, pronounced an ancient formula of initiation, which is given by A. Gellius in his interesting chapter on the subject (i. 12). In early times there were certain rules by which girls could be excused from serving as vestals, but the honor soon became so eagerly sought that these provisions were practically useless. Vows were taken by the vestal for a limited period of thirty years, after which she was free to return to private life and even to marry —a thing very rarely done (Aul. Gell., vi. 7). This period of thirty years was divided into three decades: during the first the vestal learnt her duties; during the second she practiced them; and during the third she instructed the young vestals. The special dignity of chief of the vestals, or *virgo vestalis maxima*, was reached in order of seniority. The inscriptions on the pedestals of statues of various *vestales maximæ* show that a number of different grades of honor were passed through before reaching the *maximatus* or highest dignity.[6] The duties of the vestals, besides the chief one of tending the holy fire (Cic., *De Leg.*, ii. 8) consisted in the daily bringing of water from the sacred spring of Egeria, near the Porta Capena, to be used for the ceremonial sweeping and sprinkling of the Ædes Vestæ.[1] They also offered sacrifices of salt cakes—*muries* and *mola salsa*—and poured on the altar of sacred fire libations of wine and oil, as is represented on the reverses of several first brasses and medallions of the empire (see Fig. 1). The vestals were bound to offer daily prayers for the welfare of the Roman state, and more especially in times of danger or calamity (Cic., *Pro Font.*, 21). They were also the guardians of the seven sacred objects on which the stability of the Roman power was supposed to depend:[2] the chief of these was the Palladium, a rude archaic statue of Pallas, which was said to have been brought by Æneas from the burning Troy. This sacred object was never shown to profane eyes, but it is represented on the reverse of a coin struck by Antoninus Pius in honor of his deified wife Faustina (see Fig. 1). Strict observance of the vow of chastity was one of the chief obligations of the vestals, and its breach was horribly punished by burial alive at a place near the Porta Collina known as the Campus Sceleratus (see Livy, viii. 15 and 89; Plin., *Ep.*, iv. 11; and Suet., *Dom.*, 8). Cases of unchastity and its punishment were rare; and, as the evidence against the vestal was usually that of slaves, given under torture, it is probable that in many instances an innocent vestal suffered this cruel death. The case described by the younger Pliny (*sup. cit.*) is one of special pathos, as the vestal appears to have been condemned without any sufficient evidence, simply at the wish of the emperor Domitian. A fanciful reason for this fearful punishment is given by Ovid, *Fast.*, vi. 459–460.

---

[1] [Jules Marcou, in the *Atlantic Monthly* (March, 1875) and since, contends that the name America was derived from native geographical names in Central America, and not from Vespucci.—AM. ED.]

[2] Mr. J. G. Frazer, in an interesting paper printed in the *Journal of Philology* (vol. xiv. pp. 145–172), on "the Worship of Vesta and its Connection with the Greek Prytaneum," has given many examples of a similar custom still surviving among various savage races.

[3] An allusion to the earliest method of obtaining fire by rubbing two sticks together is probably contained in the myth of Prometheus, who brought fire to mortals hidden in a hollow wand.

[4] Fire obtained in this way, that is "pure elemental fire," was commonly thought to possess a special sancity. Even throughout the Middle Ages in Catholic countries, at Easter, when the new year began, the old pagan rite still survived. On Holy Saturday all lamps in each church were extinguished, and the Paschal candlestick was lighted by the help of flint and steel. From this sacred source the other lights in the church were kindled, and the various households in the parish took a flame to relight their fires and lamps, all of which had been carefully extinguished beforehand.

[5] From the time of Augustus the emperors themselves held the office of chief pontiff, and with it the privilege of electing the vestals.

[6] These inscriptions are printed in Middleton, *Ancient Rome in* 1885, pp. 200–6, and in *Archæologia*, vol. xlix. pp. 414–422.

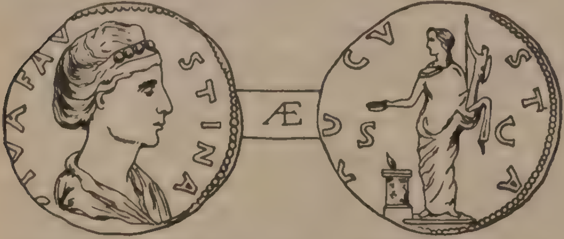

FIG. 1.—First brass struck in honor of Diva Faustina by her husband Antoninus Pius, soon after her death. On the reverse is a vestal holding the Palladium and pouring a libation on the altar of the sacred fire.

The privileges of the vestals and their influential position were very remarkable. They were exempt from any *patria potestas*, except that of the pontifex maximus, their religious father; they could dispose by will of their property, and were in most respects not subject to the Roman laws ("legibus non tenetur," Servius, on Virg., *Æn.*, xi. 204; *cf.* Gaius, i. 130, and Dion Cass., lvi. 10). This involved freedom from taxes, and the right to drive through the streets of Rome in carriages (*plostrum* and *currus arcuatus*). Some bronze plates have been found which were once attached to the carriages of vestals; the inscription on one of them runs thus, *Flaviæ Publiciæ v.v. maximæ inmunis in jugo* (see *C. I. L.*, vi. 2146–2148; *cf.* also Pruden., *Contr. Symm.*, ii. 1088). They were preceded by a lictor when appearing on state occasions, and enjoyed other semi-royal honors (Plut., *Numa*, 10, and Dion Cass., xlvii. 19). At theatres and other places of amusement they enjoyed the best seats, except at some of the nude athletic contests, from which they were excluded; they also took an important part in all the grand religious and state ceremonies, such as when the pontifex maximus offered sacrifice on the occasion of a triumph before the temple of Capitoline Jupiter. They had power to pardon any criminal they met in the street on his way to execution, provided that the meeting were accidental. The vestals alone shared with the emperors the privilege of intramural burial (Serv., *Ad Æn.*, xi. 206). During life they were richly dowered by the state (Suet., *Aug.*, 31) and had public slaves appointed to serve them (see Tac., *Hist.*, i. 43). They were also the guardians of the emperor's will, and of other important documents of state (Suet., *J. Cæs.*, 83, and *Aug.*, 101; Tac., *Ann.*, i. 8; Plut., *Anton.*, 58; and Appian, *Civ.*, v. 73). Their influence in the appointment to many offices, both religious and secular, appears to have been very great. Many of the statues to the chief vestals which were found in the Atrium Vestæ in 1883–84 have pedestals inscribed with a dedication recording that benefits had been conferred on the donor by the vestalis maxima. Lastly, they lived in a style of very great splendor: their house,[3] the Atrium Vestæ, which stood close by the Ædes Vestæ, was very large and exceptionally magnificent both in decoration and material. The discovery already mentioned of a number of statues of vestales maximæ has thrown new light on the dress of the vestals.[4] With one or two exceptions the costume of these statues is much the same: they have a long sleeveless tunic or *stola*, girdled by the *zona* immediately below the breast. One only wears the *diploidion* over the upper part of her figure. The outer garment is an ample *pallium*, wrapped round the body in a great variety of folds, and in some cases brought over the head like a hood. All seem to have long hair, showing that the process of cutting off the hair at initiation was not repeated. One figure (see Fig. 2) wears the *suffibulum*, a rectangular piece of white cloth bordered by a purple stripe, worn over the head and fastened on the breast by a *fibula*.[5] According to Festus (ed.

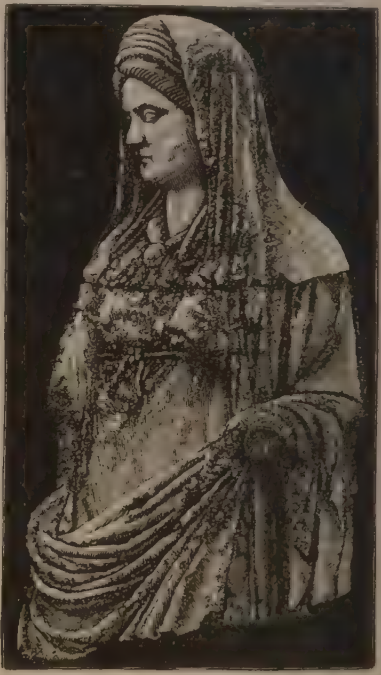

FIG. 2.—Statue of a vestalis maxima wearing the suffibulum: time of Trajan.

---

[1] The shrine of Vesta was not a *templum* in the strict Roman sense, as it was not consecrated by the augurs, its sanctity being far above the necessity of any such ceremony. Other natural springs might be used for the daily sprinkling, but it was forbidden to use water brought in a pipe or other artificial conduit (Tac., *Hist.*, iv. 5; see also Guhl and Koner, *Vit. Gr. et Rom.*, p. 654).

[2] See Cancellieri, *Le Sette Cose Fatali di Roma Antica*, Rome, 1812.

[3] For a description of this, and also of the temple of Vesta and its vicissitudes, see ROME, vol. xix. pp. 838–9; Middleton, *Ancient Rome in* 1885, pp. 181–206; and a paper by the same author in *Archæologia*, vol. xlix. p. 391 *sq.*

[4] These statues appear to have been the work of a privileged class of sculptors, who enjoyed the title of "fictores virginum vestalium,"—an honor which is recorded in some of the dedicatory inscriptions on the pedestals.

[5] The form of the *suffibulum* as shown on this statue has a curious similarity to the amice worn by the mediæval clergy.

Müller, p. 348), this sacred garment was worn by the vestals only during the act of sacrificing (see also Varro, *De Ling. Lat.*, vi. 21). This is probably the only existing statue on which this rare garment is represented. In all cases the head is closely bound by *vittæ*, rope-like twists of woollen cloth, the ends of which usually fall in loops on each shoulder (see Servius, *Ad Æn.*, x. 538).

The *Regia*, or official *fanum* of the pontifex maximus, was adjacent to the vestal's house :

> "Hic locus est Vestæ, qui Pallada servat et ignem ;
> Hic fuit antiqui Regia parva Numæ." [1]

When Augustus, after his election to the office of pontifex maximus in 12 B.C., moved his place of residence from the Regia to the Palatine, he built a new Ædes Vestæ near his palace, in the magnificent Area Apollinis. This appears to have been a copy of the older temple of Vesta. No traces of it now exist ; but Pirro Ligorio, in the latter part of the 16th century, made some sketches of what then existed of this second temple, to illustrate his great MS. on Roman antiquities, which is now preserved in the royal library at Turin (see Ovid, *Fast.*, iv. 949–954, and *Metam.*, xv. 864). The original course of the Sacra Via was supposed to have passed close to the temple of Vesta ; but excavations made in 1886 have shown that this was not the case, the supposed line of the road being really blocked by a very early structure. There is reason to believe that this formed part of the original Regia, which was rebuilt during the reign of Augustus in a more magnificent way by Domitius Calvinus, after his Spanish triumph.

The *Vestalia*, or chief festival in honor of Vesta, was held on 9th June (Ovid, *Fast.*, vi. 249), after which the temple was closed for five days for a ceremonial cleansing.[2] In private houses the feast was celebrated by a meal of fish, bread, and herbs, eaten, not on the usual triclinium, but by the domestic hearth, in front of the effigies of the Dii Penates (Ovid, *Fast.*, vi. 309–310). The feast inaugurated by Augustus in honor of Vesta Palatina was held on 28th April, the anniversary of its consecration.

With regard to statues of the goddess, though the Greek Hestia was frequently represented in plastic art, yet among the Romans Vesta appears to have been rarely so treated. The Athenian prytaneum contained a statue of Hestia. But there was no effigy in the Roman temple of Vesta, although one is commonly shown on reverses of coins which have a representation of the temple, and it appears to have been commonly thought in Rome that a statue of Vesta did exist inside her shrine,—a mistake which Ovid corrects (*Fast.*, vi. 297–300). No Roman statue now known can be certainly considered to represent Vesta, though a very beautiful standing figure of a female with veiled head (in the Torlonia collection) has, with some probability, had this name given to it.

The worship of Vesta appears to have died out slowly in the 4th century, after the adoption of Christianity as the state religion by Constantine. Zosimus (*Hist. Nov.*, v. 38) tells an interesting story of a visit made to the Atrium Vestæ at the end of the 4th century by Serena, the wife of the Vandal Stilicho, who took a valuable necklace from one of the statues, in spite of the remonstrances of an aged woman, the last survivor of the vestal virgins. Soon after that time the building appears to have fallen into decay, its valuable marble linings and other ornaments having been stripped from its walls.

Literature.—For further information the reader is referred, in addition to the works quoted above, to Lipsius, *De Vesta et Vestalibus Syntagma*, printed in Grævius, *Thes. Ant. I. L.*, vi. p. 594, No. 2131 *sq.* (J. H. M.)

VESTMENTS, in ecclesiastical law, are the garments worn during the church service by the officiating clergy. In England and Scotland before the Reformation the Vestments in use were similar to those still worn by the Roman Catholic clergy,—probably modifications of the dress of Roman citizens in their origin (see COSTUME)—and were either sacrificial, as the chasuble, or non-sacrificial, as the surplice. After the Reformation the question of vestments became of comparatively small importance in the Church of Scotland ; but in the Church of England it has in recent years been the cause of much controversy and litigation.

The "ornaments rubric" at the beginning of the Book of Common Prayer, dating from 1662, provides "that such ornaments of the church and of the ministers thereof at all times of their ministration shall be retained and be in use as were in this Church of England by the authority of parliament in the second year of the reign of King Edward VI." The reference in this rubric is to the vestments enjoined by the first prayer-book of Edward VI. (1549.) The surplice (with the addition of the hood in cathedrals and colleges, and for preaching) was the priest's dress for the service other than the communion. In the communion the bishop was to wear, besides a rochet, a surplice or alb, with a cope or vestment (also called a chasuble), and to have a pastoral staff borne by himself or his chaplain. The officiating priest was to wear a white alb, plain, with a vestment or cope, the assisting ministers albs with tunicles. The second prayer book of Edward VI. (1552) enjoined the use of the surplice only. The act of Uniformity of Elizabeth (1 Eliz. c. 2) provided for the use of the 1549 vestments, "until other order shall be therein taken by the authority of the queen's Majesty, etc." In 1564 the Advertisements of Elizabeth were issued, under which the legal vestments were fixed to be the cope worn by the principal minister, with gospeller and epistoler agreeably, in the ministration of the communion, but at ordinary services and at prayers (other than those during the ministration of the communion) said at the communion table the surplice only. Deans and prebendaries were to wear hoods. The point which the judicial committee of the privy council has been called upon more than once to decide is whether the Advertisements of Elizabeth—coupled with the Injunctions of 1559 and subsequent visitations—were such taking of "other order" as to supersede the ornaments rubric. It has been held that they were, and the effect of the decisions has been to reduce the legal vestments to the surplice and hood for all ordinary purposes, with the addition of the cope for the administration of the communion on high feast days in cathedral and collegiate churches. The cope was also allowed by the canons of 1603–4. A bishop wears in addition a rochet. The chasuble, alb, and tunicle had, as has been said, post-Reformation authority, but the girdle, amice, stole, maniple, dalmatic, and biretta were never legally recognized since that time. The stole, however, is frequently worn, by deacons generally arranged as a scarf over the left shoulder. Much information on the subject will be found in the first *Report* of the Royal Commission on Ritual, issued in 1867.

VESTRY. See PARISH, vol. xviii. p. 301.

VESUVIUS, the most celebrated volcano in the world, rises from the eastern margin of the Bay of Naples in Italy, in the midst of a region which has been densely populated by a civilized community for more than twenty centuries. Hence it has served as a type for the general popular conception of a volcano, and its history has supplied a large part of the information on which geological theories of volcanic action have been based. The height of the mountain varies from time to time within limits of several hundred feet, according to the effects of successive eruptions, but averages somewhere about 4000 feet above the sea. Vesuvius consists of two distinct portions. On the northern side a lofty semicircular cliff, reaching a height of 3747 feet, half encircles the present active cone, and descends in long slopes towards the plains below. This precipice, known as Monte Somma, forms the wall of an ancient prehistoric crater of vastly greater size than that of the present volcano. The continuation of the same wall round its southern half has been in great measure obliterated by the operations of the modern vent, which has built a younger cone upon it, and is gradually filling up the hollow of the prehistoric crater. At the time of its greatest dimensions the volcano was perhaps twice as high as it is now. By a colossal eruption, of which no historical record remains, the upper half of the cone was blown away. It was around this truncated cone that the early Greek settlers founded their little colonies.

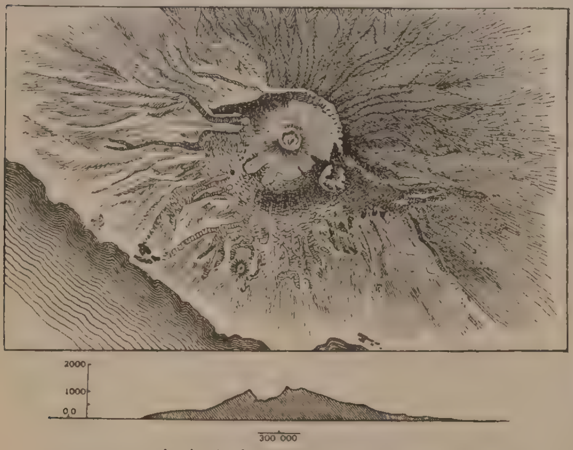
[2] The solemn decade of the *Vestalia* began on 5th June and ended on the 15th, when the temple was closed.



Plan of Vesuvius, together with north-and-south profile.

At the beginning of the Christian era, and for many previous centuries, no eruption had been known to take place from the mountain, and the volcanic nature of the locality was perhaps not even suspected by the inhabitants who planted their vineyards along its fertile slopes, and built their numerous villages and towns around its base. The sagacious and observant geographer Strabo, however, detected the probable volcanic origin of the cone and drew attention to its cindery and evidently fire-eaten rocks. From his account and other references in classical authors we gather that in the first century of the Christian era, and probably for hundreds of years before that time, the sides of the mountain were richly cultivated, but towards the top the upward growth of vegetation had not concealed the loose ashes which still remained as evidence of the volcanic nature of the place. On this barren summit lay a wide flat depression, surrounded with rugged walls of rock, which were festooned with wild vines. The present crater-wall of Somma is doubtless a relic of that time. It was in this lofty rock-girt hollow that the gladiator Spartacus was besieged by the prætor Claudius Pulcher, and from which he escaped by twisting ropes of vine-branches and descending through an unguarded notch in the crater-rim.

After centuries of quiescence the volcanic energy began again to manifest itself in a succession of earthquakes, which spread alarm far and wide through Campania. For some sixteen years after 63 these convulsions continued, doing much damage to the surrounding towns. At Pompeii, for example, among other devastation, the temple of Isis was shaken into ruins, and, as an inscription records, it was rebuilt from the foundations by the munificence of a private citizen. This preliminary earthquake phase of volcanic excitement was succeeded by a catastrophe which stands out prominently as one of the great calamities of human history. On 24th August, 79, the earthquakes, which had been growing more violent, culminated in a tremendous explosion of Vesuvius. A contemporary account of this event has been preserved in two letters of the younger Pliny to the historian Tacitus. From this narrative we can gather a tolerably clear conception of the general characteristics of the eruption: abundant and increasingly violent earthquakes, followed by an extraordinary commotion that accompanied the outburst of the volcano, when chariots would not remain still even on level ground, when houses were shaken so as to threaten destruction to their inhabitants, and when the unsteadiness of the land gave rise to great disturbance of the sea, which in its agitation retreated from the shores and left numerous marine animals uncovered; the well-known pine-tree-shaped cloud of steam, dust, and stones towering above Vesuvius and spreading out far and wide over the surrounding country; the constant flashes of lightning marking the highly electrical condition of the column of erupted material; the showers of light cinders and ashes that fell at a distance from the mountain and the rain of hot pumice and pieces of black or glowing lava around the centre of eruption; the total darkness for three days produced by the diffusion of the finer volcanic dust through the atmosphere; the fiery glare that overspread the cloud-canopy as each explosion uncovered the glowing surface of the lava column in the chimney of the volcano; and the wide covering of ashes, which like a mantle of snow was found to have been spread over the surrounding country when the darkness cleared away and the catastrophe came to an end. This eruption was attended with great destruction of life and property. Three towns are known to have been destroyed—Herculaneum at the western base of the volcano, Pompeii on the southeast side, and Stabiæ, still farther south on the site of the modern Castellamare. The exhumation of Herculaneum and Pompeii in modern times has thrown much light upon the life of Roman citizens in the first century. There is no evidence that any lava was emitted during this eruption. But the abundant steam given off by the volcano seems to have condensed into copious rain, which, mixing with the light volcanic dust, gave rise to torrents of pasty mud, that flowed down the slopes and overwhelmed houses and villages. Herculaneum is believed to have been destroyed by these "water lavas," and there is reason to suppose that similar materials filled the cellars and lower parts of Pompeii. Comparing the statements of Pliny with the facts still observable in the district, we perceive that this first recorded eruption of Vesuvius belongs to that phase of volcanic action known as the *paroxysmal*, when, after a longer or shorter period of comparative tranquillity, a volcano rapidly resumes its energy and the partially filled-up crater is cleared out by a succession of tremendous explosions. The great eruption of Krakatoa in the Sunda Strait in 1883 is a recent example of the same stage in the history of a volcano.

For nearly fifteen hundred years after the catastrophe of 79 Vesuvius remained in a condition of feeble activity. Occasional eruptions are mentioned, but none that was of importance, and their details are given with great vagueness by the authors who allude to them. By the end of the 17th century the mountain had resumed much the same general aspect as it presented before the eruption described by Pliny. Its crater-walls, some 5 miles in circumference, were hung with trees and brushwood, and at their base stretched a wide grassy plain, on which cattle grazed and where the wild boar lurked in the thickets. The central tract was a lower plain, covered with loose ashes and marked by a few pools of hot and saline water. At length, after a series of earthquakes lasting for six months and gradually increasing in violence, the volcano burst into renewed paroxysmal activity on 16th December, 1631. Vast clouds of dust and stones, blown out of the crater and funnel of the volcano, were hurled into the air and carried for hundreds of miles, the finer particles falling to the earth even in the Adriatic and at Constantinople. The clouds of steam condensed into copious torrents, which, mingling with the fine ashes, produced muddy streams that swept far and wide over the plains, reaching even to the foot of the Apennines. Issuing from the flanks of the mountain, several streams of lava flowed down towards the west and south, and reached the sea at twelve or thirteen different points. Though the inhabitants had been warned by the earlier convulsions of the mountain, so swiftly did destruction come upon them that 18,000 are said to have lost their lives.

Since this great convulsion, which emptied the crater, Vesuvius has never again relapsed into a condition of total quiescence. At intervals, varying from a few weeks or months to a few years, it has broken out into eruption, sometimes emitting only steam, dust, and scoriæ, but frequently also streams of lava. The years 1766–67, 1779, 1794, and 1822 were marked by special activity, and the phenomena observed on each of these occasions have been fully described.

The modern cone of the mountain has been built up by successive discharges of lava and fragmentary materials round a vent of eruption, which lies a little south of the centre of the prehistoric crater. The southern segment of the ancient cone, answering to the semicircular wall of Somma on the north side, has been almost concealed, but is still traceable among the younger accumulations. The numerous deep ravines that indented the sides of the prehistoric volcano, and which still form so marked a feature on the outer slopes of Somma, have on the south side served as channels to guide the currents of lava from the younger cone. But they are gradually being filled up there and will before long disappear under the sheets of molten rock that from time to time rush into them from above. On one of the ridges between these radiating valleys an observatory for watching the progress of the volcano was established many years ago by the Neapolitan Government, and is still supported as a national institution. A continuous record of each phase in the volcanic changes has been taken, and some progress has been made in the study of the phenomena of Vesuvius, and in prognosticating the occurrence and probable intensity of eruptions. A wire-rope railway (opened in the year 1880) carries visitors from the foot of the cone up to within 150 yards of the mouth of the crater.

VESZPRÉM, the chief town of a county of the same name in Hungary, lies between Lake Balaton and the forest of Bakony, about 65 miles southwest of Buda Pesth. Veszprém is the seat of a Roman Catholic bishop, whose cathedral and palace, with the county hall and the gymnasium, form the chief features of the town. Veszprém is a station on the Western Railway system. Its four annual fairs are much frequented from all parts of the trans-Danubian district, and the trade in grain, wine, and home industries generally is considerable. The town is of very ancient origin, and was known to the Romans by the name of Cimbria. The queens of the Árpád dynasty used occasionally to reside here, and even now the queens of Hungary are crowned by the bishop of Veszprém. The place suffered much during the contentions between the Turks and the Hungarians and Austrians in the 16th and 17th centuries. The population numbered 14,800 in 1886.

VETERINARY SCIENCE.

THIS science comprises a knowledge of the conformation and structure of all the domesticated animals, especially the horse; their physiology and special racial and individual characteristics; their humane management and utilization; their protection from, and medical and surgical treatment in, the diseases and injuries to which they are exposed; their amelioration and improvement; their relation to the human family with regard to communicable disorders; and the supply of food and other products, more particularly those derived from them for the use of mankind.

HISTORY.

Amongst the Greeks.

There is evidence that the Egyptians practiced veterinary medicine and surgery in very remote times; but it is not until we turn to the Greeks that we obtain any very definite information with regard to the state of veterinary as well as human medicine in antiquity. The writings of Hippocrates (460–356 B.C.) afford evidence of excellent investigations in comparative pathology. Diocles of Caristus, who was nearly a contemporary, was one of the first to occupy himself with anatomy, which he studied in animals. Aristotle, too, wrote on physiology and comparative anatomy and on the maladies of animals, while many other Greek writers on veterinary medicine are cited or copied from by Varro, Columella, and Galen. And we must not overlook Mago of Carthage (200 B.C.), whose work in twenty-eight books was translated into Greek and was largely used by Varro and Columella.

Amongst the Romans.

Until after the conquest of Greece the Romans do not appear to have known much of veterinary medicine. Varro (116–28 B.C.) may be considered the first Roman writer who deals with animal medicine in a scientific spirit, in his *De Re Rustica*, in three books, which is largely derived from the Greek writers. Celsus is supposed to have written on animal medicine; and Columella (1st century) is credited with having utilized those relating to veterinary science in the sixth and seventh parts of his *De Re Rustica*, one of the best works of its class of ancient times: it treats, not only of medicine and surgery, but also of sanitary measures for the suppression of contagious diseases. From the 3d century onwards veterinary science had a literature of its own and regular practitioners, especially in the service of the Roman armies (*mulomedici*, *veterinarii*). Perhaps the most renowned veterinarian of the Roman empire was Apsyrtus of Bithynia, who in 322 accompanied the expedition of Constantine against the Sarmatians in his professional capacity, and seems to have enjoyed a high and well-deserved reputation in his time. He was a keen observer; he distinguished and described a number of diseases which were badly defined by his predecessors, recognized the contagious nature of several maladies, and prescribed isolation for their suppression; he also made interesting observations on accidents and diseases of horses' limbs, and waged war against certain absurd empirical practices then prevailing in the treatment of disease, indicating rational methods, some of which are still successfully employed in veterinary therapeutics, such as splints for fractures, sutures for wounds, cold water for the reduction of prolapsed vagina, hot baths for tetanus, etc. Not less eminent was Hierocles, the successor of Apsyrtus, whose writings he largely copied, but with improvements and valuable additions, especially in the hygiene and training of horses. Pelagonius again was a writer of empirical tendency, and his treatment of disease in general was most irrational. Publius Vegetius (not to be confounded with Flavius Vegetius Renatus, who wrote on the military art) was a popular author of the end of the 5th century, though less distinguished than Apsyrtus, to whom and to Pelagonius he was to a great extent indebted in the preparation of his *Mulomedicina sive Ars Veterinaria.* He appears to have been more of a horse-dealer than a veterinary practitioner, and knew next to nothing of anatomy, which seems to have been but little cultivated at that period. He was very superstitious and a believer in the influence of demons and sorcerers; nevertheless he gives some interesting observations derived from his travels. He had also a good idea of aerial infection, recognized the utility of disinfectants, and describes some operations not referred to by previous writers, such as removal of calculi from the bladder through the rectum, couching for cataract, the extirpation of certain glands, and several serious operations on the horse's foot. Though inferior to several works written by his predecessors, the *Mulomedicina* of Vegetius maintained its popularity through many centuries. Of most of the ancient veterinary writers we know little beyond what can be gathered from the citations and extracts in the two great collections of *Hippiatrica* and *Geoponica* compiled by order of Constantine Porphyrogenitus in the 10th century.

In Middle Ages.

It is unnecessary to dwell here on the progress of the veterinary art during the Middle Ages. Towards the close of the mediæval period the subject was much cultivated in the cavalry schools of Italy; and Spain also had an organized system of good practitioners in the 15th century, who have left many books still extant. Germany was far behind, and literature on the subject did not exist until the end of the 15th century, when in 1492 there was published anonymously at Augsburg a *Pferdearzneibüchlein.* In the following century the influence of the Italian writers was becoming manifest, and the works of Fugger and Fayser mark the commencement of a new era. Fayser's treatises, *Von der Gestüterei* and *Von der Zucht der Kriegs- und Bürger-Pferde* (1529–1597), are remarkable for originality and good sense. In Great Britain animal medicine was perhaps in a more advanced condition than in Germany, if we accept the evidence of the *Ancient Laws and Institutes of Wales* (London, 1841); yet it was largely made up of the grossest superstitions.[1] Among the Celts the healer of horse diseases and the shoer were held in high esteem, as among the more civilized nations of Europe, and the court farrier enjoyed special privileges.[2] The earliest known works in English appeared anonymously towards the commencement of the 16th century, namely, *Propertees and Medcynes for a Horse* and *Mascal of Oxen, Horses, Sheepes, Hogges, Dogges.* The word "mascal" shows that the latter work was in its origin Italian. There is no doubt that in the 15th century the increasing taste for horses and horsemanship brought Italian riding-masters and farriers into England; and it is recorded that Henry VIII. brought over two of these men who had been trained by Grisone in the famous Neapolitan school. The knowledge so introduced became popularized, and assumed a concrete form in Blundeville's *Foure Chiefest Offices belonging to Horsemanship* (1566), which contains many references to horse diseases, and though mainly a compilation, is yet enriched with original observations. In the 15th century the anatomy of the domesticated animals, formerly almost entirely neglected, began to receive attention. A work on comparative anatomy by Volcher Koyter was issued at Nuremberg in 1573; about the same time a writer in Germany named Copho or Cophon published a book on the anatomy of the pig, in which were many original remarks on the lymphatic vessels; and Jehan Hervard in France produced in 1594 his rather incomplete *Hippo-Ostéologie.* But by far the most notable work, and one which maintained its popularity for a century and a half, was that of Carl Ruini, a senator of Bologna, published in 1598 in that city, and entitled *Dell' Anatomia e dell' Infirmità del Cavallo, e suoi Remedii.* Passing through many editions, and translated into French and German, this book was for the most part original, and a remarkable one for the time in which it was composed, the anatomical portion being especially praiseworthy. English books of the 17th century exhibit a strong tendency towards the improvement of veterinary medicine and surgery, especially as regards the horse. This is even more notable in the writings of the 18th century, among which may be particularized Gibson's *Farrier's New Guide* (1719), *Method of Dieting Horses* (1721), and (best of all) his *New Treatise on the Diseases of Horses*, besides Braken's, Burdon's, Bridge's, and Bartlett's treatises. Veterinary anatomy was greatly advanced by the *Anatomy of an Horse* (1683) of Snape, farrier to Charles II., illustrated with copperplates, and by the still more complete and original work of Stubbs, the *Anatomy of the Horse* (1766), which decidedly marked a new era in this line of study. Of foreign works it may suffice to mention that of Solleysel, *Veritable Parfait Maréschal* (1664), which passed through many editions, was translated into several languages, and was borrowed from for more than a century by different writers. Sir W. Hope's *Compleat Horseman* (1696) is a translation from Solleysel by a pupil.

Modern Schools and Colleges.

Veterinary schools

The most important era in the history of modern veterinary science commenced with the institution of veterinary schools. France was the first to take the great initiative step in this direction. Buffon had recommended the formation of veterinary schools, but his recommendations were not attended to.

In France.

Bourgelat, an advocate at Lyons and a talented hippologist, through his influence with Bertin, prime minister under Louis XV., was the first to induce the Government to establish a veterinary school and school of equitation at Lyons, in 1761. This school he himself directed for only a few years, during which the great benefits that had resulted from it justified an extension of its teaching to other parts of France. Bourgelat, therefore, founded (1766) at Alfort, near Paris, a second veterinary school, which soon became, and has remained to this day, one of the finest and most advanced veterinary schools in the world. At Lyons he was replaced by the Abbé Rozier, a learned agriculturist, who was killed at the siege of Lyons after a very successful period of school management, during which he had added largely to agricultural and physical knowledge by the publication of his *Journal de Physique* and *Cours d'Agriculture.* Twenty years later the Alfort school added to its teaching staff several distinguished professors whose names still adorn the annals of science, such as Daubenton, who taught rural economy; Vic d'Azyr, who lectured on comparative anatomy; Fourcroy, who undertook instructions in chemistry; and Gilbert, one of its most brilliant pupils, who had veterinary medicine and surgery for his department. The last-named was also a distinguished agriculturist and published many important treatises on agricultural as well as veterinary subjects. The position he had acquired, added to his profound and varied knowledge, made him most useful to France during the period of the Revolution. It is chiefly to him that it is indebted for the celebrated Rambouillet flock of Merino sheep, for the conservation of the Tuileries and Versailles parks, and for the creation of the fine experimental agricultural establishment organized in the ancient domain of Sceaux. The Alfort school speedily became the nursery of veterinary science, and the source whence all similar institutions obtained their first teachers and their guidance. A third Government school was at a later period founded at Toulouse; and these three schools have produced thousands of thoroughly educated veterinary surgeons and many professors of high scientific repute,. among whom may be named Bouley, Chauveau, Colin, Toussaint, St. Cyr, Goubaux, Arloing, and Galtier.

---

[1] See *Leechdoms, Wortcunning, and Starcraft of Early England*, 3 vols. 8vo. London, 1864.

[2] See Fleming. *Horse-Shoes and Horse-Shoeing*, London, 1869.

In Germany, etc.

Soon after the Alfort school was commenced a national school for Austria was established at Vienna by order of Maria Theresa; and this, remodelled and reorganized by Joseph II., is now the largest in the country. Prussia quickly followed suit; and soon Government veterinary schools were founded in almost every other European country, except Great Britain, mostly on a munificent scale. Probably all, but especially those of France and Germany, were established as much with a view to training veterinary surgeons for the army as for the requirements of civil life.

In the United Kingdom.

In 1790 St. Bel (whose real name was Vial, St. Bel being a village near Lyons, where was his paternal estate), after studying at the Lyons school and teaching both at Alfort and Lyons, came to England and published proposals for founding a school in which to instruct pupils in veterinary medicine and surgery. The Agricultural Society of Odiham, which had been meditating sending two young men to the Alfort school, elected him an honorary member, and delegated a committee to consult with him respecting his scheme. Some time afterwards this committee detached themselves from the Odiham Society and formed an institution styled the Veterinary College of London, of which St. Bel was appointed professor. The school was to be commenced and maintained by private subscription. In March, 1792, arrangements were made for building temporary stabling for fifty horses and a forge for shoeing at St. Pancras. The college made rapid progress in public estimation, notwithstanding considerable pecuniary embarrassments. As soon as the building was ready for the reception of animal patients, pupils began to be enrolled; and among the earliest were some who afterwards gained celebrity as veterinarians, as Bloxam, Blaine, R. Lawrence, Field, and Bracy Clark. On the death of St. Bel, in August, 1793, there appears to have been some difficulty in procuring a suitable successor; but at length, on the recommendation of John Hunter and Cline, two medical men were appointed, Coleman and Moorcroft, the latter then practicing as a veterinary surgeon in London. The first taught anatomy and physiology, and Moorcroft, after visiting the French schools, directed the practical portion of the teaching. Unfortunately, neither of these teachers had much experience among animals, nor were they well acquainted with their diseases; but Coleman had as a student, in conjunction with a fellow-student (afterward Sir Astley Cooper), performed many experiments on animals under the direction of Cline. Moorcroft, who remained only a short time at the college, afterwards went to India and during a journey in 1819 was murdered in Tibet.[1] Coleman, by his scientific researches and energetic management, in a few years raised the college to a high standard of usefulness; under his care the progress of the veterinary art was such as to qualify its practitioners to hold commissions in the army; and he himself was appointed veterinary surgeon-general to the British cavalry. Owing to the lack of funds, the teaching at the college must have been very meagre, and, had it not been for the liberality of several medical men in throwing open the doors of their theatres to its pupils for instruction without fee or reward, their professional knowledge would have been sadly deficient. The board of examiners was for many years chiefly composed of eminent members of the medical profession. Coleman died in 1839, and with him disappeared much of the interest the medical profession of London took in the progress of veterinary medicine. Yet the Royal Veterinary College (first styled "Royal" during the presidentship of the duke of Kent) continued to do good work in a purely veterinary direction, and received such public financial support that it was soon able to dispense with the small annual grant given to it by the Government. In the early years of the institution the horse was the only animal to which much attention was given. But at the instigation of the Royal Agricultural Society of England, which gave £200 per annum for the purpose, an additional professor was appointed to investigate and teach the treatment of the diseases of cattle, sheep, and other animals; outbreaks of disease among these were also to be inquired into by the officers of the college. This help to the institution was withdrawn in 1875, but renewed in 1886.

This veterinary school has been the parent of other schools in Great Britain, one of which, the first in Scotland, was founded by Prof. Dick, a student of Coleman's and a man of great perseverance and ability. Commencing at Edinburgh in 1819–20 with only one student, in three years he gained the patronage of the Highland and Agricultural Society of Scotland, which placed a small sum of money at the disposal of a committee appointed by itself to take charge of a department of veterinary surgery it had formed. This patronage, and very much in the way of material assistance and encouragement, were continued to the time of Dick's death in 1866. During the long period in which he presided over the school, considerable progress was made in diffusing a sound knowledge of veterinary medicine in Scotland and beyond it. For many years his examining board, which gave certificates of proficiency under the auspices of the Highland and Agricultural Society, was composed of the most distinguished medical men in Scotland, such as Goodsir, Syme, Lizars, Ballingall, Simpson, and Knox. By his will Dick vested the college in the lord provost and town council of Edinburgh as trustees; and left a large portion of the fortune he had made to maintain it for the purposes for which it was founded. In recent years another veterinary school has been established in Edinburgh, and one in Glasgow, both of which are doing good service.

In 1844 the Royal College of Veterinary Surgeons (to be carefully distinguished from the Royal Veterinary College) obtained its charter of incorporation. The functions of this body were, until a recent date, limited almost entirely to examining students taught in the veterinary schools, and bestowing diplomas of membership on those who successfully passed the examinations conducted by the boards which sat in London and Edinburgh. Soon after the Royal College of Veterinary Surgeons obtained its charter of incorporation a difference arose between it and Dick, which resulted in the latter seceding altogether from the union that had been established and forming an independent examining board, the Highland and Agricultural Society granting certificates of proficiency to those students who were deemed competent. This schism operated very injuriously on the progress of veterinary education and on professional advancement, as the competition engendered was of a rather deteriorating nature. After the death of Dick the dualism in veterinary licensing was suppressed: the Highland Society ceased to give certificates and the only mode of admission to the profession was through the Royal College. Since then the subjects taught have been increased in number; conformably with the requirements of ever-extending science, the period of study has been enlarged so as to be nearly as long as that imposed upon medical students; the teaching is more thorough and practical; and the examinations are more frequent and searching. Candidates for admission to the schools must also give evidence of having received a good general education. Also since the suppression of the dual system an Act of Parliament has been obtained protecting the title of the graduates of the Royal College of Veterinary Surgeons, and conferring other advantages, not the least of which is the power granted to the college to remove the names of unworthy members from its register. In some respects the Veterinary Surgeons' Act is superior to the Medical Act, while it places the profession on the same level as other learned bodies, and prevents the public being imposed upon by empirics and impostors. The college has instituted a higher degree, that of fellow, which can only be obtained after the graduate has been five years in practice and by passing a severe examination. Fellows only can be members of council or members of the examining boards. The graduates of the Royal College of Veterinary Surgeons who have been registered since its foundation in 1844 probably number 4000. In the British army there is a smaller mortality among the animals employed, and less loss from contagious diseases than in any other in Europe; this result, as well as the high efficiency of the horses, is largely due to the zeal, intelligence, and natural aptitude of the veterinary officers for their special duties. In no other army are they so severely tested, physically and professionally,—more than one-half of their service being foreign; and, in India their skill has to be exercised on elephants, camels, bullocks, cattle, and sheep, in addition to horses. During war the strain on army veterinary surgeons is very heavy; and, while surgeons are protected in the field by the Geneva Red Cross, being considered as non-belligerents, veterinary officers are regarded as combatants, and therefore run the risk of capture, imprisonment, or death at the hands of the enemy.

In India.

In India there are one or more veterinary schools in each presidency, in which natives are trained as veterinary surgeons. The need for this will be perceived when it is stated that the loss in India from preventable animal diseases alone amounts to at least £6,000,000 ($29,160,000) annually.

In the United States.

In the United States of America veterinary science has been an exotic of very slow growth. There are veterinary schools in New York, Minneapolis, and elsewhere, but these, like those in Great Britain are private institutions. To the Cornell, Pennsylvania, and Harvard universities veterinary schools or chairs have been attached with competent teachers.

---

[1] See Moorcroft and Trebeck's *Travels in Cashmere and Thibet.*

Events are at present rapidly compelling the people of the United States to realize the true value and importance of veterinary science. For many years the "lung plague" has been gradually extending itself westward, and it is now causing heavy losses. Long exempted from the more serious of the contagious diseases of animals which have scourged Europe, the United States are now invaded by all of them except two—cattle plague and the foot-and-mouth disease; and an exotic disorder of pigs, the swine plague or fever, is threatening to exterminate these animals.

The veterinary literature of this period affords striking evidence of the progress made by the science: excellent text-books, manuals, and treatises on every subject belonging to it are very numerous, and are published in every European language, while there is an abundance of periodical literature. The education—general and technical—of practitioners of veterinary medicine has, of course, been improving to a corresponding extent. The matriculation test for admission to the best veterinary schools and the fixed period for instruction in them vary but little from those of the medical schools. In Germany the veterinary schools at Berlin and Hanover have been raised to the position of universities.

Objects of the Science.

Treatment of disease.

One of the chief objects of the science is the treatment of disease in animals. Veterinary medicine has been far less exposed to the vagaries of theoretical doctrines and systems than human medicine. The explanation may perhaps be that the successful practice of this branch of medicine more clearly than in any other depends upon the careful observation of facts and the rational deductions to be made therefrom. No special doctrines seem, in later times at least, to have been adopted, and the dominating sentiment in regard to disease and its treatment has been a medical eclecticism, based on practical experience and anatomico-pathological investigation, rarely indeed on philosophical or abstract theories. In this way veterinary science has become pre-eminently a science of observation. At times indeed it has to some extent been influenced by the doctrines which have controlled the practice of human medicine—such as those of Broussais, Hahnemann, Brown, Rasori, Rademacher, and others—yet this has not been for long: experience of them when tested upon dumb unimaginative animals soon exposed their fallacies and compelled their discontinuance.

Prevention of disease.

Of more moment than the cure of disease is its prevention, and this is now considered the most important object in connection with veterinary science. More especially is this the case with those serious disorders which depend for their existence and extension upon the presence of an infecting agent, and whose ravages for so many centuries are written largely in the history of civilization. Every advance made in medicine affects the progress of veterinary science, and the recent remarkable discoveries, some of which have been initiated by members of the veterinary profession, or developed by them, must in the end create as great a revolution in veterinary practice as in the medicine of man. In "preventive medicine" the benefits to be derived from the application of the germ theory will be immense; the sanitary police measures based on this knowledge are easily framed, and, if carried rigorously into operation, must eventually lead to the extinction of these disastrous disorders.[1] The medicine of the lower animals differs from that of man in no particular so much, perhaps, as in the application it makes of utilitarian principles. The life of man is sacred; but in the case of animals, when there are doubts as to complete restoration to health and soundness, monetary considerations generally decide against the adoption of remedial measures. This feature in the medicine of the domesticated animals brings very prominently before us the value of the old adage that "prevention is better than cure." In Great Britain the value of comparative pathology in the relations it bears to human medicine, to the public health and wealth, as well as to agriculture, has been strangely overlooked or ignored; and in consequence but little allowance has been made for the difficulties the practitioner of animal medicine has to contend with. The rare instances in which animals can be seen by the veterinary surgeon in the earliest stages of disease, and when this would prove most amenable to medical treatment; delay, generally due to the inability of those who have the care of animals to perceive these early stages; the fact that animals cannot, except in a negative manner, tell their woes, describe their sensations, or indicate what and where they suffer; the absence of those comforts and conveniences of the sick room which cannot be called in to ameliorate their condition; the violence or stupor, as well as the structural arrangement and attitude of the sick creatures, which only too frequently render favorable positions for cure impossible; the slender means generally afforded for carrying out recommendations, together with the oftentimes intractable nature of these diseases; and the utilitarian influences alluded to above,—all these considerations, in the great majority of instances, militate against the adoption of curative treatment, or at least greatly increase its difficulties.

For more than forty years most destructive plagues of animals have prevailed almost continuously in the British islands without any attempt, worthy of the name, having been made to check or extirpate them until within a very recent period. Two exotic bovine diseases alone (contagious pleuro-pneumonia or lung plague and foot-and-mouth disease) are estimated to have caused the death, during the first thirty years of their prevalence in the United Kingdom, of 5,549,780 cattle, roughly valued at £83,616,854 [$406,377,910.44] while the invasion of cattle plague in 1865–1866 was calculated to have caused a money loss of from £5,000,000 [$24,300,000] to £8,000,000 [$38,880,000]. The depredations made in South Africa and Australia by the lung plague alone are quite appalling; and in India the loss brought about by contagious diseases among animals has been stated at not less than £6,000,000 [$29,160,000] annually. The damage done by tuberculosis—a contagious disease of cattle, transmissible to several kinds of animals, and possibly also to man, by means of the flesh and milk of diseased beasts—cannot be even guessed at; but it must be enormous, when we learn how widely the malady is diffused. But that terrible pest of all ages, the cattle plague, has in its two recent invasions of England been promptly suppressed with comparatively trifling loss. The foot-and mouth disease, which proved such a heavy infliction to British agriculture from its introduction in 1838, has been completely extirpated. Glanders, which annually caused the destruction of large numbers of cavalry horses, is now unknown in the army, and is rapidly disappearing from civilian stables. Rabies would soon be included in the category of extinct diseases if the indications of veterinary science were followed; and so with the other contagious maladies of animals. As for such diseases as depend for their development upon germs derived from the soil or herbage upon which animals live, and which cannot be directly controlled by veterinary sanitary measures, the system of protective inoculation with cultivated virus introduced by Pasteur will probably bring about their extinction, or at any rate greatly mitigate their effects.

Relations of veterinary to human medicine.

Veterinary science can also offer much assistance in the study and prevention of the diseases to which mankind are liable. Some grave maladies of the human species are certainly derived from animals, and others may yet be added to the list. In the training of the physician great benefit would be derived from the study of disease in animals,—a fact which has been strangely overlooked in England, as those can testify who understand how closely the health of man may depend upon the health of the creatures he has domesticated and derives subsistence from, and how much more advantageously morbid processes can be studied in animals than in our own species. Although as yet no chair of comparative pathology has been established in any British university, on the Continent such chairs are now looked upon as an almost indispensable item of every university. Bourgelat, towards the middle of the 18th century, in speaking of the veterinary schools he had been instrumental in forming, urged that "leurs portes soient sans cesse ouvertes à ceux qui, chargés par l'état de la conservation des hommes, auront acquis par le nom qu'ils se seront fait le droit d'interroger la nature, chercher des analogies, et vérifier des idées dont la conformation ne peut être qu'utile à l'espèce humaine." And the benefits to be mutually derived from this association of the two branches of medicine inspired Vicq d'Azyr to elaborate his *Nouveau Plan de la Constitution de la Médecine en France*, which he presented to the National Assembly in 1790. His fundamental idea was to make veterinary teaching a preliminary (*le premier degré*) and, as it were, the principle of instruction in human medicine. His proposal went so far as to insist upon a veterinary school being annexed to every medical college established in France. This idea was reproduced in the *Rapport sur l'Instruction Publique* which Talleyrand read before the National Assembly in 1790. In this project veterinary teaching was to form part of the National Institution at Paris. The idea was to initiate students of medicine into a knowledge of diseases by observing those of animals. The suffering animal always appears exactly as it is and feels, without the intervention of mind obscuring the symptomatology, the symptoms being really and truly the rigorous expression of its diseased condition. From this point of view, the dumb animal, when it is ill, offers the same difficulties in diagnosis as does the ailing infant or the comatose adult.

---

[1] Comp. Fleming, *Veterinary Sanitary Science and Police*, London, 1875.

Of the other objects of veterinary science there is only one to which allusion need here be made: that is the perfectioning of the domestic animals in everything that is likely to make them more valuable to man. This is in an especial manner the province of this science, the knowledge of the anatomy, physiology, and other matters connected with these animals by its students being essential for such improvement.

DISEASES OF DOMESTIC ANIMALS.

Considerations of space forbid a complete or detailed description of all the diseases, medical and surgical, to which the domesticated animals are liable. This is to be found in the current veterinary text-books. Reference will be made here only to the more important disorders of animals which are of a communicable nature, and which were not included in the article MURRAIN (*q.v.*).

Diseases of the Horse.

Nursing.

Every horseman should know something of the injuries, lamenesses, and diseases to which the horse is liable. Unfortunately not very much can be done in this direction by book instruction; indeed, there is generally too much doctoring and too little nursing of sick animals. Even in slight and favorable cases of illness recovery is often retarded by too zealous and injudicious medication; the object to be always kept in view in the treatment of animal patients is to place them in those conditions which allow nature to operate most freely in restoring health. This can best be rendered in the form of nursing, which sick animals greatly appreciate. However indifferent a horse may be to caressing or kind attention during health, when ill he certainly appreciates both, and when in pain will often apparently endeavor to attract notice and seek relief from those with whom he is familiar. Fresh air and cleanliness, quiet and comfort, should always be secured, if possible. The stable or loose box should be warm, without being close, and free from draughts. If the weather is cold, and especially if the horse is suffering from inflammation of the air-passages, it may be necessary to keep up the temperature by artificial means; but great care should be taken that this does not render the air too dry to breathe. The surface of the body can be kept warm by rugs, and the legs by woollen bandages. Yet a sick horse is easily fatigued and annoyed by too much clothing, and therefore it is better to resort to artificial heating of the stable than to overload the body or impede movement by heavy wrappings. If blankets are used, it is well to place a cotton or linen sheet under them, should the horse have an irritable skin. For bedding, long straw should be employed as little as possible, since it hampers movement. Clean old litter, sawdust, or peat-moss litter is the best. If the hoofs are strong, and the horse likely to be confined for some weeks, it affords relief to take off the shoes. Tying up should be avoided, if possible, unless it is urgently required, the horse being allowed to move about or lie down as he may prefer.

Food for a sick horse.

When a sick horse has lost his appetite, he should be tempted to eat by offering him such food as will be enticing to him. It should be given frequently and in small quantities, but should not be forced on him; food will often be taken if offered from the hand, when it will not be eaten out of the manger. Whether the animal be fed from a bucket or from a manger, any food that is left should be thrown away, and the receptacle well cleaned out after each meal. As a rule during sickness a horse requires laxative food, in order to allay fever or inflammatory symptoms, while supporting the strength. The following list comprises the usual laxative food employed: green grass, green wheat, oats, and barley, lucerne, carrots, parsnips, gruel, bran mash, linseed and bran mash, boiled barley, linseed tea, hay tea, and linseed oil. Green grass, lucerne, and similar articles of food, if cut when in a wet state, should be dried before being given. Boiled grain should be cooked with very little water, so that it may be floury and comparatively dry when ready; a little salt should be mixed with it. One gallon of good gruel may be made with a pound of meal and cold water, which should be stirred till it boils, and afterwards permitted to simmer over a gentle fire till the fluid is quite thick. To make a bran mash, scald a stable bucket, throw out the water, put in three pounds of bran and one ounce of salt, add two and a half pints of boiling water, stir up well, cover over, and allow the mash to stand for fifteen or twenty minutes until it is well cooked. For a bran and linseed mash, boil slowly for two or three hours one pound of linseed, so as to have about a couple of quarts of thick fluid, to which two pounds of bran and one ounce of salt may be added. The whole should be stirred up, covered over, and allowed to steam as before described. The thicker the mash the more readily will the horse eat it. Linseed tea is made by boiling one pound of linseed in a couple of gallons of water until the grains are quite soft. It may be economically made by using less water to cook the linseed, and afterwards making up the quantity of water to about a gallon and a half. Hay tea may be prepared by filling a bucket, after scalding it, with good sweet hay, pouring in as much boiling water as the bucket will hold, covering it over, and allowing it to stand until cold, when the fluid may be strained off and given to the horse. This forms a refreshing drink. Linseed oil, in quantities of from one-quarter to half a pint daily, may be mixed with the food; it keeps the bowels in a lax condition, has a good effect on the skin and air-passages, and is useful as an article of diet. When debility has to be combated, as in low fever or other weakening diseases, strengthening and other easily digested food must be administered, though some of the foods already mentioned, such as boiled grain, answer this purpose to a certain extent. Milk, eggs, bread and biscuits, malt liquor, corn, etc., are often prescribed with this object. Milk may be given skimmed or unskimmed; a little sugar may be mixed with it; and one or two gallons may be given daily, according to circumstances. One or two eggs may be given beaten up with a little sugar and mixed with milk, three or four times a day, or more frequently; or they may be boiled hard and powdered, and mixed in the milk. A quart of stout, ale, or porter may be given two or three times a day, or a half to one bottle of port wine daily. Scalded oats, with a little salt added, are very useful when convalescence is nearly completed. As a rule, a sick horse should have as much water as he likes to drink, though it may be necessary in certain cases to restrict the quantity, and to have the chill taken off; but it should never be warmer than 75° to 80°.

As little grooming as possible should be allowed when a horse is very weak; it should be limited to sponging about the mouth, nostrils, eyes, and forehead with clean water, to which a little vinegar may be added. Rub the legs and ears with the hand, take off the clothing, and shake or change it once a day, and if agreeable rub over the body with a soft cloth. Exercise is of course not required during sickness or injury, and the period at which it is allowed will depend upon circumstances. Care must be taken that it is not ordered too early, or carried too far at first.

How to give a ball.

Administration of Medicine.—Much care is required in administering medicines in the form of ball or bolus: and practice, as well as courage and tact, is needed in order to give it without danger to the administrator or the animal. The ball should be held between the fingers of the right hand, the tips of the first and fourth being brought together below the second and third, which are placed on the upper side of the ball; the right hand is thus made as small as possible, so as to admit of ready insertion into the mouth. The left hand grasps the horse's tongue, gently pulls it out, and places it on that part of the right side of the lower jaw which is bare of teeth. With the right hand the ball is placed at the root of the tongue. The moment the right hand is withdrawn, the tongue should be released. This causes the ball to be carried still farther back. The operator then closes the mouth and watches the left side of the neck, to note the passage of the ball down the gullet. Many horses keep a ball in the mouth a considerable time before they will allow it to go down. A mouthful of water or a handfull of food will generally make them swallow it readily. If this does not succeed, the nostrils should be grasped by the hand and held a few moments. A running halter should be used, so that the mouth may be quickly and securely closed. If the operator has not had much experience in giving balls, he should station an assistant on the near side, to aid in opening and steadying the mouth, by placing the fingers of his left hand on the lower jaw and the thumb of the right on the upper jaw. Holding the mouth in this manner facilitates the giving of the ball, and saves the operator's right hand, to a great extent, from being scratched by the horse's back teeth. It is most essential to have the ball moderately soft; nothing can be more dangerous than a hard one.

How to give a drink or drench.

To administer a drink or drench requires as much care as giving a ball, in order to avoid choking the horse, though it is unattended with risk to the administrator. An ordinary glass or stone bottle may be used, provided there are no sharp points around the mouth; but either the usual drenching horn or a tin vessel with a narrow mouth or spout is safer. It is necessary to raise the horse's head, so that the nose may be a little higher than the horizontal line. If the horse is restless, his head must be elevated by a loop of cord inserted into the mouth over the upper jaw, the prong of a stable fork being passed through it, and the handle held steady by an assistant. The drink must be given by a person standing on the right side (the assistant being in front or on the left side of the horse), the side of the mouth being pulled out a little, to form a sack or funnel, into which the medicine is poured, a little at a time, allowing an interval now and again for the horse to swallow. If any of the fluid gets into the windpipe (which it is liable to do if the head is held too high), it will cause coughing, whereupon the head should be instantly lowered. Neither the tongue nor the nostrils should be interfered with. Powders may be given in a little mash or gruel, well stirred up.

Fomentations or bathing.

If a wide surface is to be fomented (as the chest, abdomen, or loins), a blanket or other large woollen cloth should be dipped in water as hot as the hand can comfortably bear it, moderately wrung out, and applied to the part, the heat and moisture being retained by covering it with a waterproof sheet or dry rug. When it has lost some of its heat, it should be removed, dipped in warm water, and again applied. In cases of acute inflammation, it may be necessary to have the water a little hotter; and to avoid the inconvenience of removing the blanket, or the danger of chill when it is removed, it may be secured around the body by skewers or twine, the hot water being poured on the outside of the top part of the blanket by any convenient vessel. To foment the feet, they should be placed in a bucket or tub (the latter with the bottom resting wholly on the ground) containing warm water; a quantity of moss litter put in the tub or bucket prevents splashing and retains the heat longer.

Poultices.

Poultices are used for allaying pain, promoting suppuration, softening horn or other tissues, and bringing on a healthy action in wounds. To be beneficial, they should be large and always kept moist. For applying poultices to the feet, a poultice-shoe, constructed as follows, may be used with advantage: Take a circular piece of hard wood, a little longer and broader than a horse-shoe, and about one and a half inches thick. Get one surface of it rounded in a lathe, so that there may be a rise of about three-quarters of an inch in the centre, while the other surface remains flat. Round the circumference of the board nail leather, so as to form a convenient boot for retaining the poultice, similar to the one in ordinary use, except that the part which comes on the ground is rounded. The fact of its being round will enable the horse to whose foot it is applied to ease the affected spot by throwing his weight on the toe, the heel, or on either quarter, as he chooses. Poultices are usually made with bran, though this has the disadvantage of drying very quickly, to remedy which it may be mixed with linseed meal or a little linseed oil. Boiled carrots or turnips mashed make a good poultice, as does linseed meal, when mixed with boiling water (with a little olive oil added) by stirring. A charcoal poultice is sometimes used when there is a bad smell to be got rid of. It is made by mixing linseed meal with boiling water and stirring until a soft mass is produced; with this some wood charcoal in powder is mixed, and when ready to be applied some more powder is sprinkled on the surface. It may be noted that, in lieu of these materials for poultices, what is known as spongiopiline can be usefully employed. A piece of sufficient size is steeped in hot water, applied to the part, covered with a large piece of oiled silk or waterproof stuff, and secured there. Even an ordinary sponge, steeped in hot water and covered with any waterproof material, makes a good poulticing medium; it is well adapted for the throat, near the head, as well as for the space between the branches of the lower jaw.

Enemata or clysters.

Enemata or clysters are given in fevers, inflammation, constipation etc., to empty the posterior part of the bowels. They are administered by a large syringe capable of containing a quart or more of water, with a nozzle about twelve inches in length, with an ox's bladder tied to a pipe, or a large funnel with a long nozzle at a right angle; but the syringe is best. Water alone is usually applied for enemata; it should be about the temperature of the body, not less, but perhaps a degree or two more. To administer an enema, one of the horse's fore-feet should be held up, while the operator pushes the end of the nozzle, smeared with a little lard or oil, very gently and steadily for a few inches into the intestine, and then presses out the water. The amount injected will depend upon the size of the animal; two or three quarts would suffice for an ordinary-sized horse.

Epizootic and Contagious Diseases.—The epizootic diseases affecting the horse are not numerous, and may generally be considered as specific, or infectious and contagious, in their nature, circumstances of a favorable kind leading to their extension by propagation of the agent upon which their existence depends. This agent, in some of the maladies, has been proved to be a micro-organism, and there can be little doubt that it is so for all of them.

Glanders.

Glanders is one of the most serious diseases affecting horses, not only because it is incurable, but because it is very contagious. It is known in nearly every part of the world, except in Australasia. The virulent principle of glanders establishes itself most easily among horses kept in foul, badly-ventilated stables, or among such as are overworked, badly-fed, or debilitated in any way. Glanders, however, has this in common with other contagious diseases, that it is never spontaneously developed, in the absence of the virulent agent. Carnivorous animals—as lions, tigers, dogs, and cats—have become infected through eating the flesh of glandered horses; and goats, sheep, swine, and rabbits have been successfully inoculated with the virus. Men who attend on diseased horses are liable to be infected, especially if they have any sores on the exposed parts of their bodies (see GLANDERS). Though infection through wounds is the readiest way of receiving the disease, the germ or bacillus may also obtain access through the lungs, stomach, and thin mucous membranes, such as that of the eyes, nose, and lips. Glanders is presented in two forms,—one affecting the mucous membranes of the body, more particularly those of the air-passages (glanders proper), and the other attacking the skin and the superficial lymphatic vessels (farcy). Both forms are due to the same virus, and both may be acute or chronic. The acute form is the more contagious and virulent, and either destroys life quickly or becomes chronic.

Acute form.

The symptoms of acute glanders are marked by fever and its accompaniments—loss of appetite, hurried pulse and respiration, languor, and disinclination to move. Sometimes the legs or joints are swollen; but the characteristic symptoms, the classical signs, are a yellow, adhesive discharge from one or both nostrils; there is also a peculiar enlarged nodulated condition of one or both lymphatic glands between the branches of the lower jaw, which, though they may be painful, very rarely suppurate; and on the mucous membrane covering the septum of the nose are little yellow pimples or pustules, running into deep ragged-edged ulcers. The discharge from the nostril adheres to its margin, because of its glutinous nature, and straw and other matters also stick to it, while the obstruction to the respiration causes the animal to snort frequently—a cause of danger to men and animals, as this nasal discharge is virulent. In addition, the lymphatic vessels of the face are often involved and appear as corded lines passing up the cheeks; they are painful on pressure. In some cases there is a cough. As the disease progresses, the ulcers in the nostrils extend in size and depth and increase in number, often completely perforating the septum, and being sometimes covered with black crusts; the nasal discharge becomes more abundant and tenacious, streaked with blood, and foul smelling, and causes the animal the greatest difficulty in breathing, so that it appears to be on the point of suffocation. Death is due either to this cause or to exhaustion.

Chronic form.

Chronic glanders generally presents the same symptoms; but the animal is not so seriously ill, and may indeed appear to be in good health and be able to perform a certain amount of work. In some cases the ulceration may not be perceptible, and only the peculiar knotty enlarged gland and slight discharge from one nostril be evident. There may be uncertainty in such cases as to whether the disease is glanders, owing to the absence of ulceration; and, to prove whether it is that disease, recourse has to be had to inoculation of another animal, generally a worthless horse or ass, the latter being the best, as it develops the characteristic symptoms more rapidly and certainly.

Farcy.

In farcy, instead of the symptoms being manifested in the interior of the body or head, they show themselves on the skin, where the lymphatic vessels become inflamed and ulcerate. These vessels appear as prominent lines or "cords," hard and painful on manipulation, and along their course arise little tumors (the so-called "farcy buds"). These tumors ulcerate, forming sores, from which is discharged a thin glutinous pus. When the skin of the limbs is affected, these are much swollen and the animal moves with pain and difficulty. Rarely large abscesses containing thin pus form on the body. Farcy may appear during glanders or precede it, but it generally terminates in it, though the limbs and body may be covered with ulcers before this occurs.

Treatment, etc.

Medical treatment of glanders, chronic and acute, and of acute farcy should not be attempted, as the malady is incurable, while the danger of infection being transmitted to other animals or men is always real and imminent. Horses which present suspicious symptoms, or those which have been in contact or have stood in the same stable with diseased horses, should be kept apart from others, and their harness, clothing, etc., left with them. Animals which are found to be affected should be immediately destroyed and buried with proper precautions, their harness, clothing, and the utensils employed with them being either destroyed also or thoroughly cleansed, while stables and places which they have frequented should be completely disinfected. Forage and litter used by glandered horses ought to be burned or buried.

Coitus disease.

The venereal or coitus disease is a malady which occurs in Arabia and continental Europe, and has recently been carried from France to the United States of America (Montana and Illinois). In some of its features it resembles human syphilis, and it is propagated in the same manner. From one to ten days after coitus, or in the stallion not unfrequently after some weeks, there is irritation, swelling, and a livid redness of the external organs of generation (in stallions the penis may shrink) followed by unhealthy ulcers which appear in successive crops, often at considerable intervals. In mares these are near the clitoris, which is frequently erected, and the animals rub and switch the tail about, betraying uneasiness. In horses the eruption is on the penis and sheath. In the milder forms there is little constitutional disturbance, and the patients may recover in a period varying from two weeks to two months. In the severe forms the local swelling increases by intermittent steps. In the mare the vulva is the seat of a deep violet congestion and extensive ulceration; pustules appear on the perinæum, tail, and between the thighs; the lips of the vulva are parted, exposing the irregular, nodular, puckered, ulcerated, and lardaceous-looking mucous membrane. If the mare happens to be pregnant, abortion occurs. In all cases emaciation sets in; lameness of one or more limbs occurs; great debility is manifested, and this runs on to paralysis, when death ensues after a miserable existence of from four or five months to two years. In horses swelling of the sheath may be the only symptom for a long time, even for a year. Then there may follow dark patches of extravasated blood on, or swellings of, the penis; the testicles may become tumefied; a dropsical engorgement extends forward beneath the abdomen and chest; the lymphatic glands in different parts of the body may be enlarged; pustules and ulcers appear on the skin; there is a discharge from the eyes and nose; emaciation becomes extreme; a weak and vascillating movement of the posterior limbs gradually increases, as in the mare, to paralysis; and after from three months to three years death puts an end to loathsomeness and great suffering. This malady appears to be spread only by the act of coition. It is a purely contagious disorder, and cannot be generated by any known agency or cause. The indications for its suppression and extinction are therefore obvious. They are (1) to prevent diseased animals coming into actual contact, especially *per coitum*, with healthy ones, (2) to destroy the infected, and (3), as an additional precautionary measure, to thoroughly cleanse and disinfect the stables, clothing, utensils, and implements used for the sick horse.

Influenza.

Under influenza several diseases are sometimes included, and in different invasions it may (and doubtless does) assume varying forms. It may be said to be a specific fever of a low or asthenic type, associated with inflammation of the mucous membrane lining the air-passages, and also sometimes with that of other organs. At various times it has prevailed extensively over different parts of the world, more especially during the 18th and 19th centuries. Perhaps one of the most widespread outbreaks recorded was that of 1872, on the American continent. It usually radiates from the district in which it first appears. The symptoms have been enumerated as follows: sudden attack, marked by extreme debility and stupor, with increased body-temperature, quick weak pulse, rigors, and cold extremities. The head is pendent, the eyelids swollen and half closed, eyes lustreless, and tears often flowing down the face. There is great disinclination to move; the body sways on the animal attempting to walk; and the limb-joints crack. The appetite is lost and the mouth is hot and dry; the bowels are constipated and the urine scanty and high-colored; there is nearly always a deep, painful, and harassing cough; on auscultation of the chest crepitation or harsh blowing sounds are audible; and the membrane lining the eyelids and nose assumes either a bright pink color or a dull leaden hue. A white, yellowish, or greenish-colored discharge flows from the nostrils. In a few days the fever and other symptoms subside, and convalescence rapidly sets in. In unfavorable cases the fever increases, as well as the prostration, the breathing becomes labored, the cough more painful and deep, and auscultation and percussion indicate that the lungs are seriously involved, with perhaps the pleura or the heart. Clots sometimes form in the latter organ, and quickly bring about a fatal termination. When the lungs do not suffer, the bowels may, and with this complication there are, in addition to the stupor and torpor, tension and tenderness of the abdominal walls when pressed upon, manifestations of colic, great thirst, a coated tongue, yellowness of the membranes of nose and eyes, high-colored urine, constipation, and dry fæces covered with mucus. Sometimes rheumatic swelling and tenderness take place in the muscles and joints of the limbs, which may persist for a long time, often shifting from leg to leg, and involving the sheaths of tendons. At other times acute inflammation of the eyes supervenes, or even paralysis.

In this disease good nursing is the chief factor in the treatment. Comfortable, clean, and airy stables or loose-boxes should be provided, and the warmth of the body and limbs maintained. Cold and damp, foul air and uncleanliness, are as inimical to health and as antagonistic to recovery as in the case of mankind. In influenza it has been generally found that the less medicine the sick animal receives the more likely it is to recover. Nevertheless it may be necessary to adopt such medical measures as the following: For constipation administer enemata of warm water or give a dose of linseed oil or aloes. For fever give mild febrifuge diuretics (as liquor of acetate of ammonia or spirit of nitrous ether), and, if there is cough or nervous excitement, anodynes (such as extract of belladonna). When the fever subsides and the prostration is great, it may be necessary to give stimulants (carbonate of ammonia, nitrous ether, aromatic ammonia) and tonics, both vegetable (gentian, quassia, calumba) and mineral (iron, copper, arsenic). Some veterinary surgeons administer large and frequent doses of quinine from the onset of the disease, and, it is asserted, with excellent effect. If the abdominal organs are chiefly involved, demulcents may supplement the above (linseed boiled to a jelly, to which salt is added, is the most convenient and best), and drugs to allay pain (as opium and hydrocyanic acid). Olive oil is a safe laxative in such cases. When nervous symptoms are manifested, it may be necessary to apply wet cloths and vinegar to the head and neck; even blisters to the neck have been recommended. Bromide of potassium has been beneficially employed. To combat inflammation of the throat, chest, or abdomen, counter-irritants may be resorted to, such as mustard, soap liniment, or the ordinary white liniment composed of equal parts of oil of turpentine, liquor ammoniæ, and olive oil. The food should be soft mashes and gruel of oatmeal, with carrots and green food, and small and frequent quantities of scalded oats in addition when convalescence is established.

Typhoid, gastric, or bilious fever.

Typhoid, gastric, or bilious fever is often confounded with influenza, and sometimes occurs at the same time in a locality. It also appears independently in horses when shedding their coat in the autumn, in those kept in a hot, close, and impure atmosphere, and in those fed insufficiently or on badly-preserved, musty, or otherwise improper food, or supplied with water containing an excess of decomposing organic matter. Overwork or hardship predisposes to an attack. This fever seems to become contagious under certain conditions, especially in badly-ventilated insalubrious stables. Wholesome and well-aired stables are not indeed always exempt; but in them the disease is less serious and does not spread so rapidly. It is presumed that this fever is caused by some virulent principle. As "premonitory" indications of the malady, the horse appears dull and listless, and careless of food. Then signs of fever appear, in the form of staring coat, shivering, alternate heat and coldness of the surface, restlessness, a hot dry mouth, and elevation of the internal temperature of the body. The visible mucous membranes have a yellow tinge; constipation is present, and with it indications of colicky pain; the abdomen is distended, tense, and sensitive on pressure; fæces are passed in the shape of a few hard, dark-colored pellets covered with mucus; the urine is scanty, red in color, and after standing a short time deposits a heavy sediment. Sometimes there is sore throat, with increased respiration and a nasal discharge. In mild attacks convalescence may occur in from a week to ten days. In serious cases the pulse is small, feeble, and quick; the mouth is very hot and dry, and exhibits yellow, brown, or greenish patches; the abdomen is more tender and the bowels very irritable, diarrhœa of a fetid character often ensuing. Prostration to an extreme degree is a very marked feature in these cases. The head is maintained in a pendent position; the eyes become sunken; the expression is haggard and listless; while the stupor may be so advanced that pinching or pricking the skin will elicit no indication of sensibility. A fatal termination usually occurs in from ten to twenty days.

The diet must be carefully attended to, and should be soft and easily digested, such as mashes of bran, sliced carrots or turnips, boiled oats or barley, freshly cut grass, and oatmeal gruel. The stable should be kept clean and sweet, fresh air being an important factor in treatment; the body of the patient must also be made comfortable by clothing. Quiet is necessary. Quinine has been found useful in large and repeated doses; and calomel has been recommended. A daily dose of Glauber's salt may be given if there is constipation; and, if this is obstinate, enemata of warm water should be administered in addition. A drachm each of chlorate or nitrate of potash and muriate of ammonia may be given three or four times daily with the water drunk; or in cases of great prostration an ounce of oil of turpentine, sulphuric ether, sweet spirits of nitre, or carbonate of ammonia may be given as well. If there is much tenderness of the abdomen, hot fomentations continued for a long time, or mustard poultices, or the application of extract of mustard should be resorted to. When convalescence sets in, three or four ounces of tincture of gentian or cinchona may be given twice daily, with muriate of iron and stimulants.

Strangles.

Strangles is a specific contagious and infectious fever peculiar to ungulates, and is more especially incidental to young animals. It is particularly characterized by the formation of abscesses in the lymphatic glands, chiefly those between the branches of the lower jaw (submaxillary). Various causes are ascribed for its production, such as change of young horses from field to stable, from grass to dry feeding, from idleness to hard work, irritation of teething, and change of locality and climate. It is asserted that repeated attacks will occur in the same horse under the influence of the last-named cause. But the chief, if not the sole, cause is infection,—the malady, in some of its features, closely resembling the "mumps" of the human species. Langour and feverishness, diminution of appetite, cough, redness of the nasal membrane, with discharge from the eyes and nose, and thirst are among the earliest symptoms. Then there is difficulty in swallowing, coincident with the development of swelling between the branches of the lower jaw, which often causes the water in drinking to be returned through the nose and the masticated food to be dropped from the mouth. The swelling is hot and tender, diffused, and uniformly rounded and smooth; at first it is hard, with soft, doughy margins; but later it becomes soft in the centre, where an abscess is forming, and soon "points" and bursts, giving exit to a quantity of pus. Relief is now experienced by the animal; the symptoms subside; and recovery takes place. In some cases the swelling is so great or occurs so close to the larynx that the breathing is interfered with, and even rendered so difficult that suffocation is threatened. In other cases the disease assumes an irregular form, and the swelling, instead of softening in the centre, remains hard for an indefinite time, or it may subside and abscesses form in various parts of the body, sometimes in vital organs, as the brain, lungs, liver, kidneys, etc., or in the bronchial or mesenteric glands, where they generally produce serious consequences. Not unfrequently a pustular eruption accompanies the other symptoms. The malady may terminate in ten days or be protracted for months, often terminating fatally, especially when the animal is not well nursed and is kept in an unhealthy stable.

Good nursing is the chief part of the treatment. The strength should be maintained by soft nutritious food, and the body kept warm and comfortable; the stable or loose-box must have plenty of fresh air and be kept clean. The swelling may be fomented with warm water and poulticed. The poultice may be a little bag containing bran and linseed meal mixed with hot water, and applied warm to the tumefaction, being retained there by a square piece of calico, with holes for the ears and eyes, tied down the middle of the face and behind the ears. If the breathing is disturbed and noisy, the animal may be made to inhale steam from hot water in a bucket or from bran mash. If the breathing becomes very difficult, the windpipe must be opened and a tube inserted. Instead of the swelling being poulticed, a little blistering ointment is sometimes rubbed over it, which promotes suppuration. When the abscess points, it may be lanced, though it is generally better to allow it to open spontaneously.

It is very important to distinguish strangles from glanders; the character of the nasal discharge, the absence of ulcers from the nostrils, and the diffused soft swelling between the branches of the lower jaw establish the distinction between them.

Horsepox.

Horsepox, which is somewhat rare, is almost, if not quite, identical with cowpox, being undistinguishable when inoculated on men and cattle. It most frequently attacks the limbs, though it may appear on the face and other parts of the body. There is usually slight fever; then swelling, heat, and tenderness are manifested in the part which is to be the seat of eruption, usually the heels; firm nodules form, increasing to one-third or one-half an inch in diameter; the hair becomes erect; and the skin, if light-colored, changes to an intense red. On the ninth to the twelfth day a limpid fluid oozes from the surface and mats the hairs together in yellowish scabs; when one of these is removed, there is seen a red, raw depression, whereon the scab was fixed. In three or four days the crusts fall off, and the sores heal spontaneously. No medical treatment is needed, cleanliness being requisite to prevent the pocks becoming sloughs. If the inflammation runs high, a weak solution of carbolic acid may be employed.

Bibliography.—Among the numerous modern popular works in English which treat of diseases of the horse, the following may be mentioned. Robertson, *Equine Medicine* (London, 1883); Williams, *Principles and Practice of Veterinary Medicine* (2d. ed., London, 1874-79), and *Principles and Practice of Veterinary Surgery* (2d. ed., London, 1872-76); Courtenay, *Manual of Veterinary Medicine and Surgery* (London, 1886); Fleming, *Practical Horse-Keeper* (London, 1886); Gresswell, *Diseases and Disorders of the Horse* (Leeds, 1886); Fitzwygram, *Horses and Stables* (London, 1869); and Law, *The Farmer's Veterinary Adviser* (London, 1879).

Diseases of Cattle.

The diseases of the bovine species are not so numerous as those of the horse, and some of the more serious have been already alluded to (see MURRAIN). We will notice a few which have not been included among these.

Tuberculosis.

Tuberculosis is a most formidable and widespread disorder of cattle; it is assuming greater proportions every year in those countries in which it is prevalent, in consequence of no steps being taken to check or suppress it. It is infectious and contagious, can be conveyed to other species of animals by ingestion of the flesh and milk, as well as of the tuberculous material, and by inoculation of these, or inhalation of dried discharges from the lungs; it can also be transmitted from the affected animals to the fœtus in utero. Its infectious properties and ready communicability to other species render it a serious danger to mankind, through consumption as food of the flesh and milk of tuberculous cows. The disease owes its origin to a bacillus. The structures chiefly involved are the lymphatic glands and tissues,—the characteristic tubercles or "grapes" varying in size from that of a millet seed to immense masses weighing many pounds; they are found in all parts of the body, but generally in the chest and on its lining membrane, as well as in the abdominal cavity. The symptoms resemble somewhat the contagious pleuro-pneumonia of cattle in its chronic form (see MURRAIN), though tubercles, sometimes in large numbers, are often found after death in the bodies of cattle which exhibited no sign of illness during life, and which when killed were in excellent condition. When the lungs are involved, there are a peculiar phthisical cough, low fever. wasting and debility, and often enlarged throat glands, less frequently enlarged joints. If the animal is not killed, it perishes in a state of marasmus, from the difficulty experienced in breathing, or the profuse fœtid diarrhœa which ensues. Medical treatment is of little if any avail. Preventive measures are of the utmost importance. Animals free from the turberculous taint should alone be bred from, and those discovered to be affected should be at once completely segregated, and if convenient destroyed. The milk of tuberculous cows should not be given to any animal as food, not at least unless well boiled. Neither should the flesh be eaten unless well cooked throughout.

Milk or parturient fever.

Milk or parturient fever is a specific malady which appears after parturition, due to the absorption of septic matter from the interior of the uterus or vagina producing what is known as "blood-poisoning" or septicæmia. The symptoms may be briefly summarized as follows: high fever, restlessness, intense injection of the visible mucous membranes, tympanites, fœtid breath, stupor, swollen limbs, sanguinolent and perhaps purulent discharges from the vagina, foul smelling diarrhœa, coma, and death. In the early stage treatment is generally successful. The uterine cavity should be throughly cleaned out by injections of warm water, and any adherent portions of placenta removed by hand. Then a weak solution of Condy's fluid (permanganate of potash) must be injected. Cleanliness is all-important. Diffusible stimulants in large quantity should be given, with doses of solution of sulphate of quinine, perchloride of iron, oil of turpentine, or carbolic acid.

Abortion.

There is now strong evidence that one form of abortion in cows is due to infection. Whenever a case of abortion occurs in a shed, either the cow should be at once removed from the others, if they are pregnant, and cleaning and disinfection immediately resorted to; or, better still, the pregnant cows should be quickly moved out of the shed, and every care taken to keep them away from the sick cow and the discharges from it—these and the aborted fœtus being burned or otherwise completely destroyed.

Cowpox.

Cowpox is a contagious disease of much less frequent occurrence now than formerly, probably owing to improved hygienic management. In many localities the disease appears in all heifers which have recently calved on certain farms. There is usually a slight premonitory fever, which is generally overlooked; this is succeeded by some diminution in the quantity of the milk, with some increased coagulability, and by the appearance of the erruption or "pox" on the udder and teats. In well-observed cases the udder is hot and tender on manipulation for a day or two previous to the development of small pale-red nodules about the size of peas; these increase in dimensions to from three-fourths to one inch in diameter by the eighth or tenth day, when their contents have become fluid and they present a depressed centre. This fluid, at first clear and limpid, becomes yellowish-white as it changes to pus, and soon dries up, leaving a hard, button-shaped black crust, which gradually becomes detached. On the teats, owing to the handling of the milker or to the cow lying on the hard ground or on straw, the vesicles are early ruptured and sores are formed, which often prove troublesome and may cause inflammation of the udder.

Actinomycosis.

Actinomycosis, though affecting man (*cf.* vol. xviii. p. 274), horses, pigs, and other creatures, is far more common in the bovine species. The fungus (*Actinomyces*) may be found in characteristic nodules in various parts of the body, but it usually invades the bones of the jaws, upper and lower, or the soft parts in the neighborhood of these, as the tongue, cheeks, face, throat, and glands in its vicinity. About the head the disease appears to commence with slight sores on the gums or mucous membrane of the mouth or with ulcers alongside decaying teeth, and these extend slowly into the tissues. If the jaw is affected, a large rounded tumor grows from it, the dense outer bone becoming absorbed before the increasing soft growth within. Soon the whole becomes ulcerated and purulent discharges take place, in which are found the minute, hard, yellow granules which contain the fungus. When the tongue is affected, it becomes enlarged and rigid; hence the designation of "wooden tongue" given to it by the Germans. In the course of time the surface of the organ becomes ulcerated, and yellowish masses or nodules may be seen on the surface. Sometimes the entire face is involved, the lips and nostrils becoming swollen, hard, and immovable, often rendering respiration difficult. Around the throat there are rounded dense swellings, implicating the glands. When the disease is well-defined and of slight extent, the parts involved may be removed by the knife, wholly or partially. If the latter only, then the remaining affected tissues should be dressed with tincture of iodine or iodized carbolic acid. Chromic acid has also been found useful.

Diseases of Sheep.

The contagious diseases of the sheep are comparatively few, and two of the more serious have been described under MURRAIN.

Sheeppox.

The formidable disorder of sheeppox is confined chiefly to the continent of Europe. It is extremely contagious and fatal, and in these and some other characteristics resembles human smallpox. From three to twelve days after being exposed to infection the sheep appears dull and listless, and eats little if anything; the temperature rises; there are frequent tremblings; tears flow from the eyes; and there is a nasal discharge. Red patches appear inside the limbs and under the abdomen; and on them, as well as on other parts where the skin is thin, dark red spots show themselves, which soon become papules, with a deep hard base. These are generally conical, and the apex quickly becomes white from the formation of pus. This eruption is characteristic and unmistakable; and the vesicles or pustules may remain isolated (discrete pox) or coalesce into large patches (confluent pox). The latter form of the disease is serious. In bad cases the erruption may develop on the eyes and in the respiratory and digestive passages. The course of the disease lasts about three weeks or a month, and the eruption passes through the same stages as that of cowpox. The mortality may extend from 10 per cent. in mild outbreaks to 90 or 95 per cent. in very virulent ones. Diseased animals should be sheltered and fed on nourishing food, especially gruels of oatmeal, flour, linseed; acidulated water may be allowed. If there is sloughing of the skin or extensive sores, oxide of zinc ointment should be applied. But treatment should not be adopted unless there is general infection over a wide extent of country. All diseased animals should be destroyed, as well as those which have been in contact with them, and thorough disinfection resorted to.

Diseases of the Pig.

Swine plague or fever.

The pig may become affected with foot-and-mouth disease (see MURRAIN), and it also has its own particular variola. But the disease special to it, and which causes enormous losses, is swine plague. This scourge, known in America as hog cholera, is a specific contagious fever, or fevers, for it is extremely probable that two diseases are included under this designation. It is generally very rapid in its course, death ensuing in a very few days; and when the animal survives recovery is protracted. After a period of three or four days to a fortnight from exposure to infection, the animal exhibits signs of illness by dulness, weakness, shiverings, burying itself under the litter, disinclination to move, staggering gait, great thirst, hot dry snout, sunken eyes, loss of appetite, and greatly increased pulse, respiration, and temperature. Red and brown patches appear on the skin; there is a hacking cough; nausea is followed by vomiting; pressure on the abdomen causes extreme pain; diarrhœa ensues; the hind limbs become paralyzed; stupor sets in; and the animal perishes. Treatment should not be attempted when there is danger of the infection extending to other pigs. If treatment be used, nursing ought to be the chief element; sloppy food, in which small doses of carbolic acid and oil of turpentine have been mixed, should be given, and these should be followed by tonics when convalescence sets in. To suppress the disease, kill all affected pigs, and, if necessary, those which have been in contact with them; burn or bury deeply the carcases and litter; and disinfect everything likely to have been contaminated by the virus.

Diseases of the Dog.

Distemper.

The contagious diseases of the dog are likewise very few, but the one which attracts most attention is common and generally serious. This is what is popularly known as distemper. It is peculiar to the canine species, for there is no evidence that it can be conveyed to other animals, though the different families of *Carnivora* appear each to be liable to a similar disease. Distemper is a specific fever which most frequently attacks young dogs, its effects being primarily developed in the respiratory passages, though the brain, spinal cord, and abdominal organs may subsequently be involved. Highly bred and pet dogs suffer more severely than the commoner and hardier kinds. It is a most infectious disease, and there is much evidence to prove that it owes its existence and prevalence solely to its virulence. One attack confers immunity from another. The symptoms are rigors, sneezing, dulness, loss of appetite, desire for warmth, and increased temperature, respiration, and pulse. The eyes are red, and the nose, at first dry and harsh, becomes smeared with the discharge which soon begins to flow from the nostrils. Suppuration also begins at the eyes; vision is more or less impaired by the mucus and pus, and often the cornea becomes ulcerated, and even perforated. There is a cough, which in some cases is so violent as to induce vomiting. Debility rapidly ensues, and emaciation is soon apparent; diarrhœa in the majority of cases sets in; the body emits an unpleasant odor; ulceration of the mouth is noticed; the nostrils become obstructed by the discharge from them; convulsions generally come on; signs of bronchitis, pneumonia, jaundice, or other complications manifest themselves; and in some instances there is a pustular or vesicular eruption on the skin. In fatal cases the animal dies in a state of marasmus. Many which recover are affected with chorea for a long time afterwards. Here, again, good nursing is all-important. Comfort and cleanliness, with plenty of fresh air, must be ensured. Debility being the most serious feature of the disease, the strength should be maintained or restored until the fever has run its course. Light broth, beef tea, or bread and milk, or these alternately, may be allowed as diet. Preparations of quinine, given from the commencement of the attack in a little wine, such as sherry, have proved very beneficial. Often a mild laxative is required. Complications should be treated as they arise. The disease being extremely infectious, precautions should be adopted with regard to other dogs.

The formidable affliction known as RABIES (*q.v.*) has been treated of under that name.[1]

Bibliography.—J. H. Steel, *Treatise on the Diseases of the Dog;* J. W. Hill, *Management and Diseases of the Dog* (London, 1878); W. Youatt, *The Dog* (London, 1851); D. Blaine, *Canine Pathology* (London, 1851); W. Mayhew, *Diseases of the Dog* (London, 1865).

PRINCIPAL PARASITES OF DOMESTIC ANIMALS.

In horse.

Perhaps the commonest worm infesting the horse is *Ascaris megalocephala* or common lumbricoid. The males are from 6 to 8 inches long, females 7 to 17 inches. It is found in almost every part of the intestinal canal, but generally in the small intestines. The symptoms produced in the horse by this worm are colicky pains, which occur intermittently, an unhealthy condition of the skin, and staring coat. Although the animal feeds well, it does not improve in condition, but is very "tucked up," and the visible mucous membranes are very pale. In some instances pouches are formed in the coats of the intestines. There are many recipes for the expulsion of lumbricoid; among the principal remedies is a mixture of emetic tartar, oil of turpentine, and linseed oil; others are santonine, sulphate of iron, male fern, etc. *Strongylus armatus* or palisade worm was at first supposed to consist of two varieties, but it has been proved that these are simply different stages of growth of one parasite. It is a moderate-sized Nematoid worm, having a straight body, with a globular and somewhat flattened head,—males 1 to 1½ inch long, females 1½ to 2 inches. It is found in the intestines, especially the double colon and cæcum. The embryo is developed in the interior of the egg after its expulsion from the host, and is lodged in moist mud, where, according to Cobbold, it changes its first skin in about three weeks, after which it probably enters the body of an intermediate bearer, whence it is conveyed to the alimentary canal of the horse, its ultimate host, in food or water. From the stomach it bores its way into the bloodvessels, where it again changes its skin and gives rise to aneurisms. After a time it recommences its wanderings, and passes into the large intestines, where it rapidly acquires sexual maturity. It is a dung-feeder. Sometimes it passes into other tissues of the body (kidney, liver, etc.), and occasionally produces fatal results. This parasite is most dangerous to its equine host when it is migrating from one organ to another. It is principally found at the root of the anterior mesenteric artery, but it also gives rise to aneurism in the cœliac axis, the post-mesenteric and splenic arteries, and even the aorta. The common lumbricoid, the palisade worm, and the four-spined strongyle (*S. tetracanthus*) are principally productive of colic. The last-mentioned worm, of which the male and female are about the same size, ½ to ¾ inch long, is found in the cæcum, colon, and duodenum. It is a true blood-sucker, and its development is very similar to that of *S. armatus*, except that, when in the intestines in the trichonemous stage, it pierces the inner coats, encapsules itself and forms little pill-like masses, and then again enters the tissues of the intestines before becoming mature. The symptoms of its presence are loss of condition, more or less constant colicky pains, unhealthy coat, flabby muscles abdominal distension, diarrhœa, fetid and watery fæces, pale mucous membranes, great weakness, more or less frequent cough, and sometimes partial or complete paralysis, due to the formation of a clot of blood causing thrombosis of one of the principal vessels of the posterior extremities, thus interfering with the circulation of blood in the part supplied by the particular vessel. The treatment by which the common lumbricoid is expelled will suffice to expel these strongyles, but care must be exercised in administering oil of turpentine, as it very often irritates the wounds caused by *S. tetracanthus* in the coats of the intestines. Of course this treatment applies to the mature stage of these worms.

Oxyuris curvula or pin worm is fusiform in shape, with smooth gently curved body (males 1½ to 1¾ inches, females 3½ to 4¾ inches long). It is seated in the cæcum and colon; and, although not found in the rectum, it causes great irritation at the anus by the clusters of eggs which are deposited around that part in the form of yellowish crusts. This parasite is best treated by means of a cathartic, followed by sulphate of iron, also carbolic acid in 2½ per cent. solution.

The Cestodes of the horse are very insignificant, both as regards their size and the symptoms they create, the two principal being *Tænia perfoliata* and *T. plicata*. The former is the more common, but is only from 1 to 5 inches in length; it is found in the cæcum and colon, and is distinguished from *T. plicata*, not only by its length, but also by its rounder head. This last, which has a nearly square head, and is from 6 inches to 3 feet in length, occurs in the small intestines and stomach. Generally a horse may be proved to be infested with tape-worm by finding some of the proglottides in the fæces. The best remedy for the removal of *Tænia* is extract of male fern, with oil of turpentine and linseed oil, given three days in succession.

Gastrus equi or the common bot, though not a true helminth (see INSECTS, vol. xiii. p. 149), is classed with the parasites on account of its larval form living as a parasite. The bot-fly deposits its eggs on the hair of horses in such a position as to enable that animal, when licking itself, to take them into its mouth; there the warmth and moisture of the tongue, combined with the pressure of licking, cause them to burst, and from each egg a small grub escapes, which sticks to the tongue, and then passes down into the stomach, where it fixes itself to the cuticular lining of the organ by a hook which it has on each side of its mouth. There it undergoes no change (except that of growth, being at this time about 1 inch long) for about nine months, when it detaches itself, passes into the food, and is discharged with the fæces.

In cattle and sheep.

Of the parasites which infest cattle and sheep mention will only be made of *Fasciola hepatica* or common fluke, which gives rise to the disease called rot, and is more frequently met with in sheep than in cattle. For a full description of its anatomy and development, see TREMATODA, vol. xxiii. p. 573.

Strongylus micrurus is the husk-producing worm of cattle. The common earthworm is the intermediate bearer. *S. filaria*, or the common lung strongyle of sheep, is distinguished from *S. micrurus* by having no papillæ on its head. The males are 1 inch to 1 inch 2 lines long and the females nearly 3 inches. The development is unknown; but Cobbold thought that in its larval form the creature infested snails, etc. The symptoms of its presence in the sheep are a dull expression, quickened breathing, fetid breath, foaming at the mouth and nostrils, violent and spasmodic cough, loss of appetite, and emaciation. Of various specific remedies the most successful is a mixture of oil of turpentine, linseed oil, and sulphuric ether, administered two mornings in succession, followed by a third dose on the fourth morning. This causes coughing, and consequent freeing of the tubes of the larvæ and mucus. Good results have been derived from inhalation of chlorine gas, etc., which acts in the same way. The intratracheal injection of oil of turpentine is said to be followed by favorable results. The system should be supported with as much good nourishing food as possible. *S. rufescens*, or gordian strongyle (males 5 to 6 inches long, females 6 to 7 inches), is very often associated with *S. filaria*.

---

[1] [Rabies is unknown on the Pacific coast of the United States. —AM. ED.]

The principal Cestode of ruminants is *Tænia expansa*, which, when fully mature, is more frequently found in sheep than in cattle. Its body consists of about one thousand segments, each more broad than long. It is the longest of all tape-worms, being (according to Cobbold) in sheep from 8 to 30 feet and in oxen from 40 to 100 feet in length. Its maximum width is ¾ inch; it is found in the large and small intestines. Cobbold thought its larval form was developed in the louse of the ox. The symptoms are emaciation, with dysentery, and loss of appetite. Male fern ought to be given in doses according to the size of the animal. For a full account of the development of *Cysticercus bovis*, the beef measle, see TAPE-WORMS, vol. xxiii. pp. 57–8. *C. ovis* is supposed by Cobbold to be the larval form of his so-called *T. tenella* of the human subject. Another bladder worm, found only in the mesentery of the sheep, is *C. tenuicollis*, the larval form of *T. marginata* of the dog. Another important hydatid of ruminants is *Cœnurus cerebralis*, which gives rise to gid; it is generally found in the brain of sheep, cattle, goats, deer, etc., and also in the soft structures of rabbits. It is the larval form of *T. cœnurus* of the dog. The symptoms of gid are these. The animal has a rotatory motion; it does not graze freely; there is paralysis on the opposite side to the vesicle; the head is elevated or depressed if the hydatid is situated in the centre; and the animal is easily frightened. Medical treatment is of no avail; but the hydatid may be removed by a surgical operation.

Trichocephalus affinis, the common whip-worm, sometimes gives rise to severe symptoms in ruminants, particularly in sheep. The males and females are each about 2 inches long.

In the pig.

The helminths of the pig, although not very detrimental to the animal itself, are nevertheless of great importance in respect to the *Entozoa* of the human subject, being the intermediary bearers of some dangerous human parasites in their immature state. Allusion must be made to *Trichina spiralis* (see PARASITISM, vol. xviii. p. 266). The development of this parasite requires about three weeks after being taken into the stomach, where the capsule is digested; it then passes into the intestines of the pig, principally the duodenum, where it takes two days to become mature; then after about a week the embryos leave the body of the female worm, and immediately commence penetrating the walls of the intestines in order to pass into some voluntary muscles. About fourteen days elapse from the time they begin their wandering. Each is generally enveloped in a capsule, but two or even four have been found in one capsule. The male is $\frac{1}{16}$th, the female $\frac{1}{8}$th inch long, and the larvæ $\frac{1}{27}$th to $\frac{1}{30}$th inch. They have been known to live in their capsules from eighteen months to two years.

Cysticercus cellulosæ is the larval form of *Tænia solium* of man (see TAPE-WORMS, vol. xxiii. p. 55). "Measly pork" is caused by the presence in the tissues of the pig of this entozoon, which is bladder-like in form. It has also been discovered in the dog, ape, bear, rat, and deer. Other important parasites of the pig are *Stephanurus dentatus*, or crown-tailed strongyle, and *Echinorhynchus gigas*. This latter is the only thorn-headed or acanthocephalous worm infesting the domesticated animals (Cobbold).

In the dog.

The commonest of all parasites infesting the dog is *Ascaris mystax* (males 2 to 3½ inches, females 3 to 8 inches long). It is also found in the cat and larger canines. The symptoms are wasting, voracity, irregularity of bowels, short cough, and irritation at anus; in the cat, more particularly, large quantities of mucus, with numerous parasites, are vomited. The treatment consists of the administration of castor oil, with santonine, according to the size of the animal. *Filaria immitis*, another Nematode, infests the heart of the dog, and its larvæ circulate in the blood, giving rise to fits, which often end in death.

Tænia serrata is a moderate-sized Cestode, from 2 to 3 feet in length; it is found in about 10 per cent. of all English dogs, most frequently in sporting dogs, especially grayhounds and harriers, owing to their eating the intestines of rabbits, etc., in which the larval form (*Cysticercus pisiformis*) of this parasite dwells. It takes two months to pass through the first stage and one month to pass through the second when it is artificially produced, but much longer when produced naturally (Cobbold). *T. cœnurus* gives rise to gid in sheep, as previously stated. It is 18 to 24 inches long, and is principally seen in the small intestines. *T. marginata* is the largest Cestode infesting the dog. It varies in length from 5 to 8 feet, and is found in the small intestines of about 30 per cent. of dogs in Great Britain; its larval form, *C. tenuicollis*, is found in the mesentery, etc., of sheep. In the treatment of Cestodes extract of male fern has been found the most effectual remedy; areca nut and a pill consisting of colocynth and jalap, varying according to the size, age, and condition of the dog, have also proved efficacious. Comparatively small doses of any vermifuge have often been found to give rise to violent symptoms, and all vermifuges if taken in large doses produce death; too much care cannot, therefore, be exercised in administering vermifuges to young animals.

Dermatozoa.

Another order of parasites which cause numerous diseases of the skin in the domesticated animals may be classed under two heads, viz., animal parasites or *Dermatozoa* and vegetable parasites or *Dermatophyta*. The animal parasites are those which produce scab, itch, mange, etc., in all animals. This class may be again divided into three varieties, viz., *Sarcoptes*, which burrow in the skin; *Dermatodectes*, which bite the skin; and *Symbiotes*, which simply pierce the epidermis (Gerlach). All these parasites live on serous fluids, produced by the irritation which they excite. Either one or more of these varieties infest all our domesticated animals; all three varieties have been found on the horse and sheep, the last two on the ox, and one in the pig, dog, and cat respectively. The sarcoptic variety of the horse and dog is easily transmitted to man. To distinguish between the different varieties, it is only necessary to place a few fresh scales in the sun; if *Sarcoptes* are present, they will soon be found on the under surface, whereas *Dermatodectes* are on the upper surface. Again, the *Sarcoptes* are isolated, whereas the *Symbiotes* and *Dermatodectes* live in clusters or colonies. Thirdly, the *Symbiotes* do not burrow, but merely bite the skin, and principally invade the limbs. An effectual cure for those which infest the horse is a mixture of sulphur, hellebore, oil of turpentine, whale oil, and carbolic acid, applied for three successive days, then washed off and applied again. For the dog a very useful remedy is made from creosote, olive oil, solution of potassium, and sulphur, also train oil and spirits of tar. The first is an almost sure cure for cats. A good remedy for destroying lice may be compounded from *staphisagria* powder, soft soap, and hot water, applied warm to the skin.

Dermatophyta.

Vegetable parasites are of two kinds, namely, *Tinea tonsurans*, or the common ringworm, seen in most of our domesticated animals, and *Favus*, or honeycomb ringworm. The latter is seldom seen. *T. tonsurans* is due to a cryptogamic parasite, *Tricophyton*, and is lodged in the interior of the roots of the hairs, which after a time lose their elasticity and break off, leaving the fungi in the form of a grayish white bran-like incrustation. In this they differ from *Favus*, which is yellow and covers the epidermis. It may affect any part of the body, but occurs principally on the head, face, neck, and hindquarters; it is very prevalent amongst young cattle. Ringworm is very contagious, and may be communicated from one animal to another, and from animals to man. It mostly attacks badly-fed and ill-cared-for animals. The affected parts should be well washed with soft soap and warm water, removing as much as possible of the bran-like scales, and then with Stockholm tar ointment, and finally with either iodine (in tincture or ointment) or carbolic acid (in solution or ointment).

(G. FL.)

VETO. By this expression (Lat. *veto*, "I forbid") is understood in public law the constitutional right of the competent authority, or in republics of the whole people in their primary assembly, to protest against a legislative or administrative act, and to prevent wholly, or for the time being, the validation or execution of the same.

It is generally stated that this right was called into existence in the Roman republic by the *tribunicia potestas*, because by this authority decisions of the senate, and of the consuls and other magistrates, could be declared inoperative. Such a statement must, however, be qualified by reference to the facts that *interdico*, *interdicimus* were the expressions used, and, in general, that in ancient Rome every holder of a magistracy could check a negotiation set on foot by a colleague, his equal in rank, by his opposition and intervention. This was a consequence of the position that each of the colleagues possessed the whole power of the magistracy, and this right of intervention must have come into existence with the introduction of colleagued authorities, *i.e.*, with the commencement of the republic. In the Roman magistracy a twofold power must be distinguished,—the positive management of the affairs of the state entrusted to each individual and the power of restraining the acts of magistrates of equal or inferior rank by his protest. As the *tribuni plebis* possessed this latter negative competence to a great extent, it is customary to attribute to them the origin of the veto.

In the former kingdom of Poland the precedent first set in 1652 was established by law as a constant right, that in the imperial diet a single deputy by his protest "Nie pozwalam," *i.e.*, "I do not permit it," could invalidate the decision sanctioned by the other members. The king of France received the right of a suspensory veto at the commencement of the French Revolution, from the national assembly sitting at Versailles in 1789, with regard to the decrees of the latter, which was only to be valid for the time being against the decisions come to and during the following national assembly, but during the period of the third session it was to lose its power if the assembly persisted in its resolution. By this means it was endeavored to diminish the odium of the measure; but, as is well known, the monarchy was soon afterwards entirely abolished. Similarly the Spanish constitution of 1812 prescribed that the king might twice refuse his sanction to bills laid twice before him by two sessions of the cortes, but if the third session repeated the same he could no longer exercise the power of veto. The same is the case in the Norwegian constitution of 1814.

In the present French republic the president has no veto, except against decisions of the general councillors (*conseils générals du departments*), just as the prefect possesses the same power against decisions of the communal councillors. The king or queen of England has the right to withhold sanction from a bill passed by both houses of parliament. This royal prerogative has not been exercised since 1692 and may now be considered obsolete. The governor of an English colony has the power of veto against a bill passed by the legislative body of a colony, *e.g.*, Canada. In this case the bill is finally lost, just as a bill would be which had been rejected by the colonial council, or as a bill passed by the English houses of parliament would be if the crown were to exert the prerogative of refusing the royal assent. The governor may, however, without refusing his assent, reserve the bill for the consideration of the crown. In that case the bill does not come into force until it has either actually or constructively received the royal assent, which is in effect the assent of the English ministry, and therefore indirectly of the imperial parliament. Thus the colonial liberty of legislation is made legally reconcilable with imperial sovereignty, and conflicts between colonial and imperial laws are prevented.[1]

The constitution of the United States of North America contains in art. i., sect. 7, § 2, the following order:

> "Every bill which shall have passed the House of Representatives and the Senate shall, before it becomes a law, be presented to the president of the United States; if he approve, he shall sign it; if not, he shall return it with his objections to that house in which it shall have originated, who shall enter the objections at large on their journal and proceed to reconsider it. If, after such reconsideration, two-thirds of that house shall agree to pass the bill, it shall be sent, together with the objections, to the other house, by which it shall likewise be reconsidered, and, if approved by two-thirds of that house, it shall become a law. Every order, resolution, or vote to which the concurrence of the Senate and House of Representatives may be necessary (except on a question of adjournment) shall be presented to the president of the United States, and, before the same shall take effect, shall be approved by him, or, being disapproved by him, shall be repassed by two-thirds of the Senate and House of Representatives, according to the rules and limitations prescribed in the case of a bill."

In most States of the Union the governors, in the same manner or to a modified extent, possess the right of protesting against the laws and decisions of the legislature. Here, therefore, we have again a suspensory veto which is frequently exercised. According to the official report for 1886, the president of the United States exercised his right of veto in that year 115 times against bills, resolutions, and orders of the most different kinds. Between 1840 and 1850 the Whigs agitated for the total abolition of the power of veto. Of late an agitation has begun in the opposite direction.[2]

According to the constitution of the German empire of 1871, the imperial legislation is executed by the federal council and imperial diet; the emperor is not mentioned. In the federal council the simple majority of votes decides. But in the case of bills concerning the army, the navy, and certain specially noted taxes, as well as in the case of decisions concerning the alteration of orders for the administration, and arrangements for the execution of the laws of customs and taxes, the proposal of the federal council is only accepted if the Prussian votes are on the side of the majority in favor of the same (art. 7, sect. 3). Prussia presides in the federal council. The state of things is therefore in fact as follows: it is not the German emperor, but the same monarch as king of Prussia, who has the right of veto against bills and decisions of the federal council, and therefore can prevent the passing of an imperial law. The superior power of the presidential vote obtains, it is true, its due influence only in one legislative body, but in reality it has the same effect as the veto of the head of the empire.

The Swiss federal constitution grants the president of the Confederation no superior position at all; neither he nor the federal council possesses the power of veto against laws or decisions of the federal assembly. But in some cantons, viz., St. Gall (1831), Basel (1832), and Lucerne (1841), the veto was introduced as a right of the people. The citizens had the power to submit to a plebiscite laws which had been debated and accepted by the cantonal council (the legislative authority), and to reject the same. If this plebiscite was not demanded within a certain short specified time, the law came into force. But, if the voting took place, and if the number of persons voting against the law exceeded by one vote half the number of persons entitled to vote in the canton, the law was rejected. The absent voters were considered as having voted in favor of the law. An attempt to introduce the veto in Zurich in 1847 failed. Thurgau and Schaffhausen accepted it later. Meanwhile another arrangement has quite driven it out of the field. For of late years the so-called "referendum,"—properly speaking, direct legislation by the people,—has been introduced into most of the Swiss cantons. Formerly in all cantons—with the exception of the small mountainous districts of Uri, Schwyz, Unterwalden, Zug, Glarus, and Appenzell—it was not a pure democracy, but a representative constitution that prevailed: the great councillors or cantonal councillors periodically chosen by the people were the possessors of the sovereign power, and after deliberating twice passed the bills definitely. Now they have only to discuss the bills, which are printed and sent to all voters with an explanatory message; then the people on a certain day vote for the acceptance or rejection of the law by writing "yes" or "no" on a printed voting-paper which is placed in an urn under official control. In some cantons important financial resolutions involving large state expenses are also submitted to the decision of the people. In the revised federal constitution of 1874, under certain suppositions which have no further interest for us at present, a facultative referendum (*i.e.*, the possibility of demanding a plebiscite under exceptional circumstances) has been introduced for federal laws. Since that period it has often been employed and has operated like a veto. It is evident that by the compulsory referendum in the cantons the mere veto is rendered superfluous.[1]

In examining the question as to what position the veto occupies in jurisprudence, we must separate quite different conceptions which are comprised under the same name.

1. The veto may be a mere *right of intervention* on the part of a magistrate against the order of another official, or against that of an authority of equal or inferior rank. This was the case in ancient Rome. To this class belong also those cases in which, in the present French republic, the president makes his "no" valid against decisions of the general councillors, and the prefect does the same against decisions of the communal councillors. The use of the expression here is quite justifiable, and this veto is not confined to bills, but refers particularly to administrative measures. It affords a guarantee against the abuse of an official position.

2. The veto may be a safety-valve against precipitate decisions, and so a *preventive measure.* This task is fulfilled by the suspensory veto of the president of the North American Union. Similarly, to this class belong the above-mentioned prescriptions of the Spanish and Norwegian constitutions, and also the veto of the governor of an English colony against decisions of the legislature; for this protest is only intended to prevent a certain want of harmony between the general and the colonial legislation, by calling forth a renewed investigation. This veto is neither an interference with the competence of an authority, nor a division of the legislative power among different factors, but simply a guarantee against precipitancy in the case of a purely legislative measure. The wisdom of establishing this veto power by the constitution is thus manifest.

3. It is wrong to apply the term veto to what is merely the *negative side of the sanctioning of the laws,* in other words an act of sovereignty. It would not be in accordance with the nature of a constitutional monarchy to declare the monarch's consent to a law unnecessary, or make it a compulsory duty; the legislative power is divided between him and the chambers. The sovereign must therefore be perfectly at liberty to say "yes" or "no" in each single case according to his opinion. If he says the latter, we speak of it as his veto, but this—if he possesses an absolute and not merely a suspensory veto—is not an intervention and not a preventive measure, but the negative side of the exercise of the legislative power, and therefore an act of sovereignty. That this right belongs fully and entirely to the holder of sovereign power—however he may be called—is self-evident.

One chamber can also by protest prevent a bill of the other from coming into force. The "placet of the temporal power for church affairs—when it occurs—also involves in this manner in itself the veto or non placet." Where in pure democracies the people in their assembly have the right of veto or referendum, the exercise of it is also a result of the sovereign rights of legislature.

The peculiar power of veto possessed by the (Prussian) president of the federal council of Germany lies on the boundary between (2) and (3). (A. V. O.)

VIAREGGIO, a coast town of Italy, in the province of Lucca, 13 miles by rail north-northwest from Pisa, had in 1881 a population of 10,190 (commune 12,735). The principal industry is fishing, and the place is also a favorite sea-bathing resort.

VIATICUM. This word, which in classical Latinity means "provision for a journey" (Gr. *τὰ ἐφόδια*), is often used by early Christian writers to denote the sacrament of the Eucharist, and sometimes even is applied to baptism. Ultimately it came to be employed in a restricted sense to denote the last communion given to the dying. The 13th canon of the council of Nice is to the effect that "none even of the lapsed, shall be deprived of the last and most necessary viaticum (*ἐφοδίου*)," and that the bishop, on examination, is to give the oblation to all who desire to partake of the Eucharist on the point of death. The same principle still rules the canon law, it being of course understood that penitential discipline, which in ordinary circumstances would have been due for their offence, is to be undergone by lapsed persons who have thus received the viaticum, in the event of recovery.

In extreme cases it is lawful to administer the viaticum to persons not fasting. The ritual to be observed in its administration does not differ from that laid down in the office for the communion of the sick, except in the words of the formula, which is "accipe, carissime frater (carissima soror), viaticum corporis nostri Jesu Christi, quod te custodiat ab hoste maligno, protegat te, et perducat te ad vitam æternam. Amen."

VIATKA. See VYATKA.

VIAU, or VIAUD, THÉOPHILE DE (1590–1626), more commonly called both in his own time and since simply THÉOPHILE, a poet of unfortunate life and of great but misused powers, was born at Clairac near Agen in 1590. He went to the capital in his twentieth year and ingratiated himself with at least one patron, the ill-fated duke of Montmorency, who was always constant to him. He also became acquainted with most of the literary men of the time, and in 1617 composed and produced with success the tragedy of *Pyrame et Thisbé*. This piece, written in the extravagant Spanish-Italian manner which was fashionable in the interval between the Pléiade model and the innovations of Corneille, was later the subject of much ridicule, especially directed to the passage in which a sword, reddened with the blood of its master, is said to "blush for its treason," no very unpardonable conceit in eyes less pedantic than Boileau's. Théophile's prosperity was not lasting. Only two years after the success of *Pyrame* he was accused of blasphemous and indecent writings, and was exiled to England. Returning in 1621 and joining the Roman Church (he had been a Huguenot), he served in two campaigns. But he was, rightly or wrongly, associated with the publication of the *Parnasse Satirique,* a collection of poems of the same character as those which had formerly got him into trouble, and in 1623 was tried, condemned in his absence to death, arrested, and imprisoned in the conciergerie. At length the sentence of death which hung over him was reduced to banishment, and the influence of Montmorency enabled him to hide himself in Paris till his death on 25th September, 1626.

For his singular persecution, which, even if the charges had been much better established than they are, would have been surprising enough in an age of unusually loose conduct and writing, the machinations of the Jesuits are sometimes held responsible. But if Théophile had bitter enemies he had warm friends. Six years after his death Georges de Scudéry edited his work with a *Tombeau* (copy of obituary verses), and a challenge in the preface to any one who might be offended by the editor's eulogy of the poet. This was in 1632; the year before had appeared a tragedy entitled *Pasiphaë*, where the awkwardness of the subject is not redeemed by any merit of treatment; but it is by no means certainly or even probably Théophile's, and is not included in his works, the standard modern edition of which is that of Alleaume in the Bibliothèque Elzévirienne (Paris, 2 vols., 1856). These works may surprise the reader who only knows Théophile's mishaps and ill-fame; for, though varied enough, they contain in the certainly authentic part of them nothing discreditable. Besides *Pyrame et Thisbé*, the chief in point of bulk is a paraphrase, half verse half prose, after the odd fashion of the time, of the *Phædo*. There are numerous French and Latin letters, a vigorous *Apologie* rebutting the accusations against him, a promising fragment of comic prose narrative, and a large collection of occasional verses, odes, elegies, stanzas, etc. These latter, besides being very unequal, are distinguished by the faults of taste and the inelegance of language which marked the first quarter of the century. But there are occasionally bursts of real poetry; and on the whole Théophile is the superior of all his contemporaries between Regnier and Corneille. In addition to Alleaume's edition, a delightful article in Gautier's *Grotesques* should be consulted respecting him.

[1] A. v. Orelli, *Das Staatsrecht der schweizerischen Eidgenossenschaft*, pp. 101 and 105, and Marquardsen, *Handbuch des öffentlichen Rechts der Gegenwart in Monographien*, vol. iv. Freiburg (in Breisgau), 1885.

VIBORG, or **WIBORG** (Finnish, *Viipuri*), capital of a province or län of the same name in Finland, is situated at the head of the Bay of Viborg in the Gulf of Finland, at the mouth of the Saima Canal and on the railway which connects St. Petersburg with Helsingfors. The Saima Canal (37 miles long), a fine engineering work, connects with the sea Lake Saima—the principal lake of Finland, 249 feet above sea-level—and a series of others, including Puruvesi, Orivesi, Höytiänen, and Kallavesi, all of which are navigated by steamers, as far north as Idensalmi in 63° 30′ N. lat. Viborg is thus the seaport of Karelia and eastern Savolaks, with the towns of Vilmanstrand (1289 inhabitants in 1880), St. Michel (1432), Nyslott (1424), Kuopio (1834), and Idensalmi, with their numerous saw-mills and iron-works. Viborg stands most picturesquely on the glaciated and dome-shaped granite hills surrounding the bay, which is protected at its entrance by the naval station of Björkö, and at its head by several forts. The castle of Viborg built in 1293 by Marshal Torkel Knutson, was the first centre for the spread of Christianity in Karelia, and for establishing the power of Sweden; it is now used as a prison. Its lofty and elegant tower has fallen into decay. The court-house (1839), the town-house, the gymnasium (1641; with an excellent library), and the museum are among the principal buildings of the city. There are also a school of navigation and several primary schools, both public and private, a literary and an agricultural society, and several benevolent institutions. The population, 14,668 in 1880 and 15,800 in 1884, consists of three elements,—Finnish, Swedish, and Russian (see FINLAND). There is a strong Russian garrison. Several industrial establishments, including a foundry for the construction of steam-engines, an iron-work, and several candle-works, match-factories, and saw-mills, have risen of late at Viborg and in its neighborhood; but the place owes its chief importance to its export trade, in which timber is the chief item. The coasting trade is also considerable.

The environs are most picturesque and are visited by many tourists in the summer. The park of Monrepos (Old Viborg), in a bay dotted with dome-shaped islands, is specially attractive. The scenery of the Saima Canal and of the Finnish lakes with the grand *ås* of Pungaharju; the Imatra rapids, by which the Vuoksen discharges the water of Lake Saima into Lake Ladoga, with the castle of Kexholm at its mouth; Serdobol and Valamo monastery on Lake Ladoga—all visited from Viborg—attract many tourists from St. Petersburg and from other parts of Finland.

VICAR, in ecclesiastical law, is, in the words of Blackstone, "a curate, deputy, or vicegerent of the appropriator, and therefore called *vicarius* or vicar." When a benefice had become appropriated before the dissolution of the religious houses to a spiritual corporation, usually with the authority of a license from the Chancery, the vicar was the person appointed by the appropriators for the cure of souls in the parish. He was at first generally a member of the corporation. After the dissolution in the reign of Henry VIII. these appropriated benefices became—as indeed they had been in the church in general up to the Lateran council of 1179—vested in lay impropriators,[1] but the legal position of the vicar remained the same. He was not a parson in the proper sense of the word (in fact parson and vicar are often distinguished in old statutes), and his stipend was at the discretion of the impropriator. Where he had the enjoyment of tithes, they were in most cases, apart from prescription, the small as distinguished from the great tithes, that is, such as the impropriator found it most difficult to collect. There was, however, no consistent rule in the matter: what were rectorial tithes in some parishes might be vicarial in others. The position of the vicar, at first so insecure and uncertain, was gradually ameliorated by legislation. 15 Ric. II. c. 6 provided for the sufficient endowment of the vicarage. 4 Hen. IV. c. 12 repeated this provision, and in addition enacted that the vicar should be a secular priest, not removable at the caprice of the appropriators, and canonically instituted and inducted. Among numerous other Acts may be noticed 29 Car. II. c. 8, making perpetual temporary augmentations of vicarages, and 3 Geo. IV. c. 72, enabling them to be in certain cases converted into rectories. In Scotland vicarage teinds were the subject of many Acts of the Scottish parliament. Until they became a fixed burden on the land they were payable out of minor and accidental products, were established by usage, and lost by negative prescription. 27 and 28 Vic. c. 33 provided for the commutation of those vicarage teinds of fish which had not up to then been commuted.

Perpetual Curate.—Where a benefice was appropriated *ad mensam monachorum* or was from any other cause without the services of a regular vicar, it did not fall within the statutes relating to vicars, and was served by a temporary curate, generally a regular ecclesiastic belonging to the appropriating corporation. After the dissolution the curate in charge became perpetual, inasmuch as he could not be removed except by the bishop. By 2 and 3 Vict. c. 49 every church or chapel augmented by the governors of Queen Anne's Bounty and having a district is a perpetual curacy; so, as a rule, are new churches built under the Church Building Acts. By 31 and 32 Vict. c. 117 the incumbent of every parish or new parish for ecclesiastical purposes, not being a rector, is to be styled the vicar, and his benefice is to be designated a vicarage. This Act only confers a more honorable name upon the perpetual curate; it does not in any way alter his legal position.

Vicar-general is the deputy of the archbishop of Canterbury or York. In his court the bishops of the province are confirmed. How far he has any contentious jurisdiction appears uncertain. In the confirmation of Dr. Hampden as bishop of Hereford in 1848 the vicar-general of Canterbury refused to hear objections to the confirmation by the dean and chapter of Hereford, and the Court of Queen's Bench was equally divided as to whether such refusal was good in law. *Vicar-choral* is a clerk in orders who assists at cathedral services. See further ADVOWSON, BENEFICE, PARISH, PARSON, QUEEN ANNE'S BOUNTY, TITHES.

VICENTE, GIL (*c.* 1470 – *c.* 1536), Portuguese dramatist, with an honorable position also in the history of Spanish literature, was born, most probably in Lisbon, about the year 1470. He was of good family, and, after studying law, at the then university of Lisbon, became attached to the royal court, in what capacity is unknown. In June, 1502, he produced and took the leading part in the performance of his first piece, a kind of dramatic pastoral, after the manner of Juan de la Encina, on occasion of the birth of an heir to the throne (John III.). So successful was this appearance that he soon became the recognized provider of such entertainments at court, during the reign both of Emmanuel and of John. Of his domestic history nothing is known, except that he married a lady named Branca Bezerra, by whom he had a son and a daughter. His outward circumstances, especially in his later years, if some apparently personal allusions in his works are to be literally interpreted, do not seem to have been prosperous. Almost the only personal incident that has come down to us is his successful remonstrance with the clergy of Santarem in 1531, for having taken the earthquakes of that year as a text from which to rouse orthodox fanaticism against the Jews or "Neo-Christians;" the circumstances are related by Vicente in a letter to the king. The time and place of his death are alike uncertain; most probably it occurred at Evora not much later than 1536.

---

[1] *Appropriation* is the term for the possession of a benefice by a spiritual corporation, *impropriation* for its possession by a layman.

Vicente published various of his pieces during his lifetime, but the first collected edition of his works, edited by his son Luis, did not appear till 1562. It is in black letter folio, and only one copy, that in the Göttingen university library, is now known to exist. A second edition, "emended by the Holy Office," appeared in 1585, of which also only a single copy is now extant (in Lisbon). The disfavor with which they were viewed by the Inquisition caused them to fall into unmerited neglect, and they do not appear to have been again reprinted till 1834, when they were carefully edited by Feio and Monteiro (Hamburg, 3 vols.). They number forty-two in all, of which seventeen are written wholly in Portuguese and ten wholly in Spanish, while in the remainder both languages are employed. The principles determining his choice of language are not easy to discover, and indeed he seems to have used either indifferently, perhaps in this accomodating himself to the aptitudes of particular actors. It may be observed, however, that, while in the 14th century it had been fashionable for all court poets in the western half of the peninsula to use Galician or Old Portuguese, the practice had changed in the days of John II. of Castile, when Castilian became the favorite speech. In writing chiefly in Portuguese Vicente thus reverted to the older practice; but, on the other hand, it is not surprising that he should have freely used Spanish at a court which stood in such intimate personal relations with that of Castile (of Emmanuel's three wives two were Castilian princesses and the third was a sister of Charles V.), and where he had taken Encina as his avowed model. According to their form the works of Vicente are conveniently divided into—(1) *obras de devoçao* or *autos*, (2) comedies and tragi-comedies, and (3) farces. The first class includes twelve autos or sacred pieces, intended for performance at Christmas, Epiphany, and other religious festivals. The plots are quaint and conceived entirely in the mediæval spirit; in their working out many touches of poetical feeling and also of sarcastic humor are introduced. There is a vein of pleasing romance in such compositions as his *Dom Duardos* and *Amadis de Gaula*, while the genuine mirthfulness of his farces *Inez Pereira* and others), as well as their originality, well entitle him to be spoken of by his compatriots as their "father of comedy" and the national Plautus.

Some typical examples of Vicente's works may be read in Böhl von Faber's *Teatro Español anterior á Lope de Vega* (Hamburg, 1832) and in Ochoa's *Tesoro del Teatro Español* (Paris, 1838). An interesting essay, with analyses of many of the plays, occurs in vol. lxxix. of the *Quarterly Review* (1846–47). see also Ferdinand Wolf's article "Gil-Vicente" in Ersch and Gruber's *Encykl.* (sec. i. vol. lxvii.)

VICENZA, a town of Italy, capital of the province of Vicenza, lies at the northern base of the Monti Berici, on both sides of the Bacchiglione, immediately below its confluence with the Retrone, and 42 miles by rail to the west of Venice. It is surrounded by somewhat dilapidated walls, about 3 miles in circumference, and entered by six gates. Though many of the streets are narrow and irregular, the town has a number of fine public buildings, many of them the work of PALLADIO (*q.v.*). Among these are the town-hall, otherwise known as the Basilica, one of the finest works of the Renaissance period, of which Palladio himself said that it might stand comparison with the similar work of antiquity. The prefecture and the Barbarano and Chieregati Palaces are also his work; in the last-named the civic museum is housed. The Olympic theatre is also noteworthy. The cathedral, which is Gothic, dating mainly from the 13th century, consists of a nave with eight chapels on each side; it contains examples of the Montagnas and of Lorenzo da Venezia. Several of the other churches contain noteworthy paintings; thus the Romano-Gothic church of San Lorenzo has Montagnas, S. Corona Montagnas and a G. Bellini, and S. Stephano one of the most important works of Palma Vecchio. The principal square contains two columns, dating from the Venetian period, and a tall Gothic campanile. Of the Palladian villas in the neighborhood La Rotonda or Villa Palladiana, 1½ miles to the southeast, deserves special mention. Vicenza is the see of a bishop, and contains two gymnasia, a seminary, an academy, a public library, a botanic garden, and various hospitals. Some remains of antiquity, including ruins of a theatre and an aqueduct, have been preserved. The most important manufacture is that of silk, which employs a large proportion of the inhabitants. Great numbers of mulberry trees are grown in the neighborhood. Woollen and linen cloth, leather, earthenware, paper, and articles in gold and silver are also made in Vicenza, and a considerable trade in these articles, as well as in corn and wine, is carried on. The population of the town in 1881 was 24,331, or, including the suburbs, 27,694.

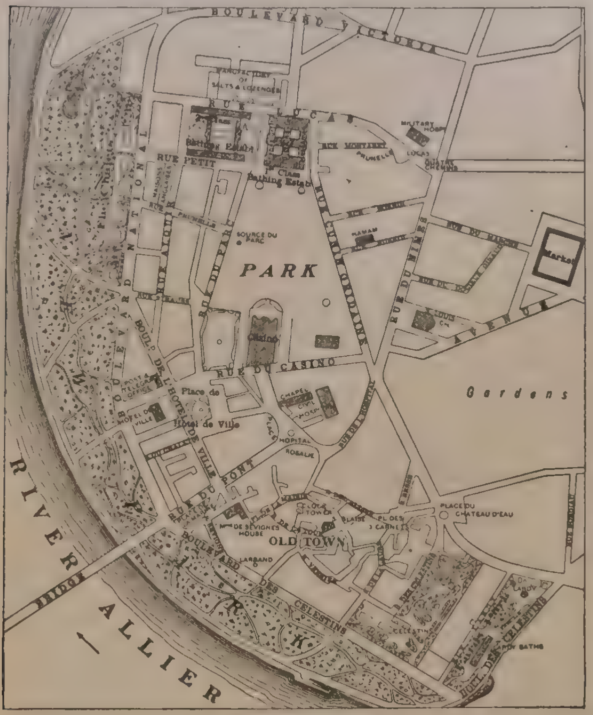
Vicenza is the *Vicentia* or *Vicetia* of the Romans, noticed by Strabo as one of the minor towns of Venetia. It continued to be a municipal town of some importance till the fall of the Western empire, and suffered severely in the invasion of Attila, by whom it was laid waste. It was for some time during the Middle Ages an independent republic, but was subdued by the Venetians in 1405. Towards the end of the 15th century it became the seat of a school of painting, of which the principal representatives were, besides Bartolomeo Montagna, its founder, Giovanni Speranza and Benedetto Montagna. Palladio (1518–80) was a native of Vicenza.

VICH, a town of Spain, in the province of Barcelona, 38 miles by rail to the north of that town, lies in a small side valley of the Ter, about 1500 feet above sea-level. It is irregularly built on a hill slope, and has narrow ill-paved streets; there are some quaint old houses in the Plaza Mayor. The cathedral, begun about 1040, belongs chiefly to the first half of the 14th century, but with some mischievous alterations of the 18th. The interior, with three naves and a transept, is elegant, and the Gothic cloisters (1340) are particularly fine. The industries include tanning and the weaving of linen and woollen fabrics; and sausages are a speciality of the place. There are mines of copper and coal in the neighborhood. The population within the municipal boundaries in 1877 was 12.478.

Vich, the *Ausa* of the ancient geographers, was the chief town of the Ausetani; in the Middle Ages it was called Ausona and Vicus Ausonensis, hence Vic de Osona, and simply Vich.

VICHY, a town of France, in the department of Allier, is situated on the right bank of the Allier, 227 miles by rail south-southeast from Paris and 6 south of St. Germaines-de-Fossés, where the railway lines to Lyons and Nîmes separate. The population in 1881 was 8322, and in 1886 10,072.

Vichy owes its importance to its mineral waters, which were celebrated in the time of the Romans. Within the town or in its immediate vicinity there are 21 springs, 12 of which are state property (4 of these obtained by boring). The waters of those which are outside the town are brought in by means of aqueducts. The most celebrated and frequented are the Grande Grille, L'Hopital, the Célestins, and Lardy. The most copious of all, the Puits Carré, is reserved for the baths. All these, whether cold or hot (maximum temperature, 113° Fahr.), are largely charged with bicarbonate of soda (see MINERAL WATERS, vol. xvi. p. 452); some also are chalybeate and tonic. The waters, which are limpid, have an alkaline taste and emit a slight odor of sulphuretted hydrogen. They are recommended in cases of stomachic and liver complaint, also for diabetes, gravel, and gout. The thermal establishment, begun in 1787, is capable of supplying 3500 baths a day. The company by which the state baths are farmed also manufactures pastilles, barley-sugar, and digestive chocolate, as well as salts for artificial baths. A considerable trade is carried on in the natural waters. In addition to the principal establishment, Vichy has a hospital bath, the hydropathic establishments of Lardy and Larbaud, and a large military hospital, founded in 1843. Cusset (5356 inhabitants in 1886), chef-lieu of the canton, about 1 mile distant, has similar mineral waters and a bathing establishment. Vichy possesses a casino and two public parks. The promenade commands a splendid view of the mountains of Auvergne. At Vichy, Cusset, and in the neighborhood there are cotton cloth manufactures (*toiles de Vichy*).



Plan of Vichy.

VICKSBURG, a city of the United States and the county seat of Warren county, Mississippi, the largest and most important city in the State, stands on the bluffs, on the east bank of the Mississippi, nearly midway between Memphis and New Orleans. It is situated in the midst of the most fertile cotton region of the country, and is one of the principal inland shipping ports of that staple. Its means of communication, besides the river, embrace three important railroad systems. The city has some manufacturing industries, particularly of lumber and cotton-seed oil and cake. The population in 1880 was 11,814, showing a slight decrease since 1870; and in 1888 it was estimated at 18,000. Nearly one-half of the population were colored.

Prior to the Civil War, Vicksburg was an important river port, having in 1860 a population of 4591. Its growth had, however, been slow. During the war, it became a very strong strategic point, as it controlled the navigation of the Mississippi, and a contest for its possession was waged for several months with heavy loss of life. Finally, General Grant captured it in 1863, and with it the Confederate army of General Pemberton, numbering 27,000 men. For a few years after the war, the city gained rapidly in population and importance.

VICO, Giovan Battista (1668–1744), Italian jurist and philosopher, was the son of Antonio Vico, a small bookseller, and was born at Naples on 23d June, 1668. At the age of seven he had a serious fall and severely injured his head, which produced in him "the melancholy and sour temper suited to men of talent." Afterwards he applied himself to the study of scholastic philosophy. At an early age, he entered the university, and made such rapid progress, especially in jurisprudence, that he is said to have won a suit for his father at the age of sixteen. Nevertheless, he preferred the study of history, literature, juridical science, and philosophy. Being appointed teacher of jurisprudence to the nephews of the bishop of Ischia, G. B. Rocca, he accompanied them to the castle of Vatolla, near Cilento, in the province of Salerno. There he passed nine studious years, chiefly devoted to classical reading, Plato and Tacitus being his favorite authors, because "the former described the ideal man and the latter man as he really is." On his return to Naples he found Cartesianism in the ascendant, and this he disliked. Belonging to no particular school or literary sect, he languished in neglect and obscurity, until in 1697 he gained the professorship of rhetoric at the university, with a scanty stipend of 100 ducats [gold $144.17?]. On this he supported not only himself but his rapidly increasing family; for he had married a poor and illiterate girl, who was only able to put her mark to the nuptial contract. Meanwhile, his own studies were pursued with untiring zeal, and he began to write and publish his works. Two modern authors exercised a weighty influence on his mind—Francis Bacon and Grotius. He was no follower of their ideas, indeed often opposed to them; but he derived from Bacon an increasing stimulus towards the investigation of certain great problems of history and philosophy, while Grotius proved valuable in his study of philosophic jurisprudence. In 1708 he published his *De ratione studiorum*, in 1710 *De antiquissima Italorum sapientia*, in 1720 *De universi juris uno principio et fine uno*, and in 1721 *De constantia jurisprudentis.* On the strength of these works he offered himself as a candidate for the university chair of jurisprudence then vacant, with a yearly stipend of 600 ducats [gold $865.02?]. But he was rejected by the examiners, although all his competitors have remained unknown to fame. Without any sense of discouragement, he returned to his favorite studies, and in 1725 published the first edition of the work that forms the basis of his renown, *Principii d'una Scienza Nuova.* In 1730 he produced a second edition of the *Scienza Nuova*, so much altered in style and with so many substantial additions that it was practically a new work. In 1735 Charles III., of Naples marked his recognition of Vico's merits by appointing him historiographer-royal, with a yearly stipend of 100 ducats [$144.17?]. But the philosopher derived little enjoyment from his new post. Attacked by a cruel malady, mind and memory failed. But during frequent intervals of lucidity he resumed his pen and made new corrections in his great work, of which a third edition appeared in 1744, prefaced by a letter of dedication to Cardinal Trojano Acquaviva. Vico expired on 20th January of the same year. Fate seemed bent on persecuting him to the last. A fierce quarrel arose over his burial between the brotherhood of St. Stephen, to which he had belonged, and the university professors, who desired to escort his corpse to the grave. Finally, the canons of the cathedral, together with the professors, buried the body in the church of the Gerolimini.

Vico has been generally described as a solitary soul, out of harmony with the spirit of his time and often directly opposed to it. In fact, though living during the later years of the 17th and the early part of the 18th century, when Locke had already given to the world the germs of the ideas afterwards developed in the philosophy of the Encyclopædists, he followed an entirely opposite line of thought. The writer who was the first to declare that great men are the representatives and personifications of their times would thus seem to have been the living contradiction of his own theory. Nevertheless a closer inquiry into the social conditions of Vico's time, and of the studies then flourishing, shows him to have been thoroughly in touch with them.

Owing to the historical past of Naples, and its social and economic condition at the end of the 17th century, the only study that really flourished there was that of law; and this soon penetrated from the courts to the university, and was raised to the level of a science. A great school of jurisprudence was thus formed, including many men of vast learning and great ability, although little known to fame. This school stood apart, as it were, from the rest of the world; the works of its representatives were inelegant, and often indeed exaggeratedly legal and scholastic in style. Accordingly, they attracted little notice in upper Italy and were totally ignored beyond the Alps. But, while outside Naples scarcely anything was known of Marcello Marciano the younger, Domenico Aulisio, Duke Gaetano Argento, Niccolò Capasso, and many others, there were three men who rose to great eminence and attained to an honorable rank in general literature both in Italy and abroad. By an exposition of the political history of the kingdom, based on a study of its laws and institutions and of the legal conflicts between the state and the court of Rome, Pietro Giannone was the first initiator of what has been since known as civil history. Giovan Vincenzo Gravina, the patron and preceptor of Metastasio, and also noted as a literary critic, wrote a history of Roman law, specially distinguished for its accuracy and elegance. While Gravina studied the successive and varying forms of Roman law and sought to give them an historical explanation, Vico raised the problem to a higher plane, by tracing the origin of law in the human mind and explaining the historical changes of the one by those of the other. Thus he made the original discovery of certain ideas which constitute the modern historic method, or rather the psychologico-historic method. This problem he proceeded to develop in various works, until in his *Scienza Nuova* he arrived at a more complete solution, which may be formulated as follows. If the principle of justice and law be one, eternal, and immutable, why should there be so many different codes of legislation? These differences are not caused by difference of nationality only, but are to be noted in the history of the same people. The clearest, most precise, and most constant conception of law was undoubtedly that of the Romans; nevertheless, Roman jurisprudence underwent so many transformations as apparently to constitute almost different codes. How was so strange a fact to be explained? This question is touched upon in his *Orations or Inaugural Addresses* (*Orazioni o Prolusioni*) and in his *Minor Works* (*Scritti Minori*). Finally he applied himself to its solution in his *Universal Law* (*Diritto Universale*), which is divided into two books. The first of these, *De uno et universi juris principio et fine uno*, was subdivided into two parts; so likewise was the second, with the respective titles of *De constantia philologiæ* and *De constantia jurisprudentis*.

The following is the general idea derived from these researches. Vico held God to be the ruler of the world of nations, but ruling, not as the providence of the Middle Ages by means of continued miracles, but as He rules nature, by means of natural laws. If, therefore, the physicist seeks to discover the laws of nature by study of natural phenomena, so the philosopher must seek the laws of historical change by the investigation of human events and of the human mind. According to Vico, law emanates from the conscience of mankind, in whom God has infused a sentiment of justice, and is therefore in close and continual relation with the human mind, and participates in its changes. This sentiment of justice is at first confused, uncertain, and almost instinctive, is, as it were, a divine and religious inspiration instilled by heaven into the primitive tribes of the earth. It is an unconscious, universal sentiment, not the personal, conscious, and rational sentiment of the superior few. Hence the law to which it gives birth is enwrapped in religious forms which are likewise visible and palpable inasmuch as primitive man is incapable of abstract, philosophical ideas. This law is not the individual work of any philosophical legislator, for no man was, or could be, a philosopher at that time. It is first displayed in the shape of natural and necessary usages consecrated by religion. The names of leading legislators, which we so often find recorded in the history of primitive peoples, are symbols and myths, merely serving to mark an historic period or epoch by some definite and personal denomination. For nations, or rather tribes, were then distinguished by personal names only. The first obscure and confused conception of law gradually becomes clearer and better defined. Its visible and religious forms then give way to abstract *formulæ*, which in their turn are slowly replaced by the rational manifestation of the philosophic principles of law that gains the victory in the final stage of development, designated by Vico as that of civil and human law. This is the period of individual and philosophic legislators. Thus Roman law has passed through three great periods,—the divine, the heroic, and the human,—which are likewise the three chief periods of the history of Rome, with which it is intimately and intrinsically connected. Nevertheless, on careful examination of these three successive stages, it will easily be seen that, in spite of the apparent difference between them, all have a common foundation, source, and purpose. The human and civil philosophic law of the third period is assuredly very different in form from the primitive law; but in substance it is merely the abstract, scientific, and philosophic manifestation of the same sentiment of justice and the same principles which were vaguely felt in primitive times. Hence one development of law may be easily translated into another. Thus in the varied manifestations of law Vico was able to discover a single and enduring principle (*De universi juris uno principio et fine uno*). On these grounds it has been sought to establish a close relation between Vico and Grotius. The latter clearly distinguished between a positive law differing in different nations and a natural law based on a general and unchanging principle of human nature, and therefore obligatory upon all. But Vico was opposed to Grotius, especially as regards his conception of the origin of society, and therefore of law. Grotius holds that its origin was not divine, but human, and neither collective, spontaneous, nor unconscious, but personal, rational, and conscious. He believed moreover that natural law and positive law moved on almost constant and immutable parallel lines. But Vico maintained that the one was continually progressing towards the other, positive law showing an increasing tendency to draw nearer to natural and rational law. Hence the conception that law is of necessity a spontaneous birth, not the creation of any individual legislator; and hence the idea that it necessarily proceeds by a natural and logical process of evolution constituting its history. Vico may have derived from Grotius the idea of natural law; but his discovery of the historic evolution of law was first suggested to him by his study of Roman law. He saw that the history of Roman jurisprudence was a continuous progress of the narrow, rigorous, primitive, and almost iron law of the XII. Tables towards the wider, more general, and more humane *jus gentium*. Having once derived this conception from Roman history, he was easily and indeed necessarily carried on to the next,—that the positive law of all nations, throughout history, is a continual advance, keeping pace with the progress of civilization, towards the philosophic and natural law founded on the principles of human nature and human reason.

As already stated, the *Scienza Nuova* appeared in three different editions. The divergences between the second and third are of too little moment to be recorded here. But the first and second editions are almost distinct works. In the former the author sets forth the analytical process by which the laws he discovered were deduced from facts. In the second he not only enlarges his matter and gives multiplied applications of his ideas, but also follows the synthetic method, first expounding the laws he had discovered and then proving them by the facts to which they are applied. In this edition the fragmentary and jerky arrangement, the intricate style, and a peculiar and often purely conventional terminology seriously checked the diffusion of the work, which accordingly was little studied in Italy and remained almost unknown to the rest of Europe. Its fundamental idea consists in that which Vico, in his peculiar terminology, styles "poetical wisdom" (*sapienza poetica*) and "occult wisdom" (*sapienza riposta*), and in the historical process by which the one is merged in the other. He frequently declares that this discovery was the result of the literary labors of his whole life.

Vico was the first thinker who asked, Why have we a science of nature, but no science of history? Because our glance can easily be turned outwards and survey the exterior world; but it is far harder to turn the mind's eye inwards and contemplate the world of the spirit. All our errors in explaining the origin of human society arise from our obstinacy in believing that primitive man was entirely similar to ourselves, who are civilized, *i.e.*, developed by the results of a lengthy process of anterior historic evolution. We must learn to issue from ourselves, transport ourselves back to other times, and become children again in order to comprehend the infancy of the human race. As in children, imagination and the senses prevailed in those men of the past. They had no abstract ideas; in their minds all was concrete, visible, and tangible. All the phenomena, forces, and laws of nature, together with mental conceptions, were alike personified. To suppose that all mythical stories are fables invented by the philosophers is to write history backwards and confound the instinctive, impersonal, poetic wisdom of the earliest times with the civilized, rational, and abstract occult wisdom of our own day. But how can we explain the formation of this poetic wisdom, which, albeit the work of ignorant men, has so deep and intrinsic a philosophic value? The only possible reply is that already given when treating of the origin of law. Providence has instilled into the heart of man a sentiment of justice and goodness, of beauty, and of truth, that is manifested differently at different times. The ideal truth within us, constituting the inner life that is studied by philosophers, becomes transmuted by the facts of history into assured reality. For Vico physiology and history were the two poles of the new world he discovered. After having extolled the work of God and proclaimed Him the source of all knowledge, he adds that a great truth is continually flashed on us and proved to us by history, namely, "that this world of nations is the work of man, and its explanation therefore only to be found in the mind of man." Thus poetical wisdom, appearing as a spontaneous emanation of the human conscience, is almost the product of divine inspiration. From this, by the aid of civilization, reason, and philosophy, there is gradually developed the civil, occult wisdom. The continual, slow, and laborious progress from the one to the other is that which really constitutes history, and man becomes civilized by rendering himself the conscious and independent possessor of all that in poetical wisdom remained impersonal, unconscious, came as it were from without by divine *afflatus*.

Vico gives many applications of this fundamental idea. The religion of primitive peoples is no less mythical than their history, since they could only conceive of it by means of myths. On these lines he interprets the whole history of primitive Rome. One book of the second edition of the *Scienza Nuova* is devoted to "The Discovery of the True Homer." Why all the cities of Greece dispute the honor of being his birthplace is because the *Iliad* and the *Odyssey* are not the work of one, but of many popular poets, and a true creation of the Greek people which is in every city of Greece. And because the primitive peoples are unconscious and self-ignorant Homer is represented as being blind. In all parts of history in which he was best versed Vico persues a stricter and more scientific method, and arrives at safer conclusions. This is the case in Roman history, especially in such portions as related to the history of law. Here he sometimes attains, even in details, to divinations of the truth afterwards confirmed by new documents and later research. The aristocratic origin of Rome, the struggle between the patricians and the plebeians, the laws of the XII. Tables, not, as tradition would have it, imported from Greece (but the natural and spontaneous product of ancient Roman customs), and many other similar theories were discovered by Vico, and expounded with his usual originality, though not always without his usual blunders and exaggerations.

Vico may be said to base his considerations on the history of two nations. The greater part of his ideas on poetical wisdom were derived from Greece. Nearly all the rest, more especially the transition from poetical to occult wisdom, was derived from Rome. Having once formulated his idea, he made it more general in order to apply it to the history of all nations. From the savage state, through the terror that gives birth to religions, through the creation of families by marriage, through burial rites and piety towards the dead, men approach civilization with the aid of poetic wisdom, and pass through three periods,—the divine, heroic, and human,— in which they have three forms of government, language, literature, jurisprudence, and civilization. The primary government is aristocratic. Patrician tyranny rouses the populace to revolt, and then democratic equality is established under a republic. Democratic excesses cause the rise of an empire, which, becoming corrupt, declines into barbarism, and, again emerging from it, retraces the same course. This is the *law of cycles*, constituting that which is designated by Vico as the "eternal ideal history, or rather course of humanity, invariably followed by all nations." It must not be held to imply that one nation imitates the course pursued by another, nor that the points of resemblance between them are transmitted by tradition from one to the other, but merely that all are subject to one law, inasmuch as this is based on the human nature common to all alike. Thus, while on the one hand the various cycles traced and retraced by all nations are similar and yet independent, on the other hand, being actually derived from Roman history, they become converted in the *Scienza Nuova* into a bed of Procrustes, to which the history of all nations has to be fitted by force. And wherever Vico's historical knowledge failed he was led into increased error by this artificial and arbitrary effort.

It has been justly observed by many that this continuous cyclical movement entirely excludes the progress of humanity towards a better future. It has been replied that these cycles are similar without being identical, and that, if one might differ from another, the idea of progress was not necessarily excluded by the law of cycles. Vico undoubtedly considered the poetic wisdom of the Middle Ages to be different from that of the Greeks and Romans, and Christianity to be very superior to the pagan religion. But he never investigated the question whether, since there is a law of progressive evolution in the history of different nations, separately examined, there may not likewise be another law ruling the general history of these nations, every one of which must have represented a new period, as it were, in the history of humanity at large. Therefore, although the *Scienza Nuova* cannot be said absolutely to deny the law of progress, it must be allowed that Vico not only failed to solve the problem but even shrank from attacking it.

He had no followers or admirers even in Naples, where the ideas of Tanucci, Filangieri, Genovesi, and Galiani prevailed, men who sometimes appear to be more French than Italian. When at last, with the German reaction initiated by Kant against the sense philosophy of the French, an entirely new philosophy arose, and many ideas started by Vico were revived on a more rigorous method, supported by more accurate research and with a wider and firmer grasp of knowledge, the name of the Neapolitan philosopher was forgotten, and no one recognized how much was owed to him. Nevertheless it may be asserted that between the close of the 17th and the early part of the 18th century, when the thought of the world was bent in a totally different direction, Vico was the first to discern and proclaim the course by which, in the present age, historical, moral, and political science was destined to make such great and assured progress.

See Cantoni, *G. B. Vico, Studii Critici e Comparativi* (Turin, 1867); Flint. *Vico* (Edinburgh and London, 1884). For editions of Vico's own works, see *Opere*, ed. Giuseppe Ferrari (Milan, 1834-35, 6 vols.), and Michelet, *Œuvres Choisies de Vico* (Paris, 1835, 2 vols.). Mamiani, Rosmini, Gioberti, and many other Italian philosophers have treated at length of Vico in their works. The most detailed account of him is Ferrari's essay, "La Mente de Vico," prefacing his edition of the *Opere*. (P. V.)

VICTOR I., St., bishop of Rome from about 190 to 202, succeeded Eleutherus and was followed by Zephyrinus. His name is chiefly associated with a display of intolerance towards the bishops of Asia Minor for the view they took in the Quartodeciman controversy (see EASTER; also POPEDOM, vol. xix. p. 504); he also excommunicated Theodotus of Byzantium on account of his doctrine as to the Person of Christ (see MONARCHIANISM).

VICTOR II., one of the series of German popes and the successor of Leo IX., was consecrated in St. Peter's, Rome, on 13th April, 1055. His father was a Swabian baron, Count Hartwig von Calw, and his own baptismal name was Gebhard. At the instance of Gebhard, bishop of Ratisbon, uncle of the emperor Henry III., he had been appointed while still a young man to the see of Eichstädt; in this position his great talents soon enabled him to render important services to Henry, whose chief adviser he ultimately became. His nomination to the papacy by Henry at Mainz, in September, 1054, was made at the instance of a Roman deputation headed by Hildebrand, whose policy doubtless was to detach from the imperial interest one of its ablest supporters. In June, 1055, Victor met the emperor at Florence, and held a council, which anew condemned clerical marriages, simony, and the alienation of the estates of the church. In the following year he was summoned to Germany to the side of the emperor, and was with him when he died at Botfeld in the Harz on 5th October, 1056. As guardian of Henry's infant son, and adviser of the empress Agnes, Victor now wielded enormous power, which he began to use with much tact for the maintenance of peace throughout the empire and for strengthening the papacy against the aggressions of the barons. He died shortly after his return to Italy, at Arezzo, on 28th July, 1057. His successor was Stephen IX. (Frederick of Lorraine).

VICTOR III., pope from 24th May, 1086, to 16th September, 1087, was the successor of Pope Gregory VII. Son of Landolfo V., prince of Benevento, he was born in 1027; in his thirtieth year he entered the cloister at Monte Cassino, changing his name of

Dauferius into Desiderius. He soon became abbot of the monastery, and in 1059 Nicolas II. raised him to the cardinalate. He rendered many important services to Gregory VII., who accordingly on his deathbed indicated him to the cardinals of south Italy as his worthiest successor. He was elected on 24th May, 1086, but showed genuine reluctance to accept the embarrassing honor thus thrust upon him, and after his tardy consecration, which did not take place till 9th May, 1087, he withdrew at once to Monte Cassino. The countess Matilda soon afterwards induced him to return to Rome; but owing to the presence of the antipope Clement III. (Guibert of Ravenna), who had powerful partisans, his stay there was short. In August he held at Benevento a synod of some importance, at which Clement III. was excommunicated, lay-investiture forbidden, and a kind of crusade proclaimed against the Saracens in Africa. During the synod Victor fell ill, and betook himself to Monte Cassino, where he died on 16th September, 1087. His successor was Urban II.

VICTOR IV. Two antipopes have claimed this name; (1) Cardinal Gregorio Conti, who was chosen by a party in succession to the antipope Anacletus II. in 1138, but through the influence of Bernard of Clairvaux was induced two months afterwards to make his submission to Innocent II.; and (2) Cardinal Octavianus, the Ghibelline antipope, elected in 1159, and countenanced by the emperor Frederick Barbarossa. He died at Lucca on 20th April, 1164.

VICTOR, CLAUDE PERRIN (1764–1841), duke of Belluno, marshal of France, was born at La Marche (Vosges) on 7th December, 1764. In 1781 he entered the army as a common soldier, and after ten years' service he received his discharge and settled at Valence. Soon afterwards he joined the local volunteers and in less than a year had risen to the command of a battalion. He greatly distinguished himself on the Italian frontier, and for his bravery at the siege of Toulon in 1793 he was raised to the rank of brigadier-general. He afterwards served for some time with the army of the eastern Pyrenees, and in the Italian campaign of 1795–97 he so acquitted himself at Mondovi, Roveredo, Porto Legnago, and many other places that he was promoted to be general of a division. After the peace of Campo Formio he for some time commanded the forces in the department of La Vendée; but in 1798 he was again in Italy and in the battle of Marengo especially took a very important part. In 1803 he became commander-in-chief of the Bavarian army, and after the peace of Amiens he acted for eighteen months as French plenipotentiary at Copenhagen. On the outbreak of hostilities with Prussia he joined the fifth army corps as chief of the general staff; at the battle of Friedland he commanded the first corps in such a manner that Napoleon made him marshal of the empire on the field. After the peace of Tilsit he became governor of Prussia, and in 1808 he was created duke of Belluno. In the same year he was sent to Spain, where he took a prominent part in military affairs, until his appointment in 1812 to command the ninth army corps destined to operate in Russia. Here his most important service was in protecting the retreating army at the crossing of the Berezina. He took an active part in the wars of 1813–14, till in February of the latter year he had the misfortune to arrive too late at Montereau-sur-Yonne. The result was a scene of violent recrimination and his deprivation by the emperor who transferred his command to Gérard. Thus wounded in his amour propre, Victor now transferred his allegiance to the Bourbon dynasty, and in December, 1814, received from Louis XVIII. the command of the second military division. In 1815 he accompanied the king to Ghent, and on the second restoration he was made a peer of France and major-general of the royal guard. In 1821 he was appointed war minister and held this office for two years. After the revolution of 1830 he retired altogether into private life. His death took place at Paris on 3d March, 1841.

VICTOR, SEXTUS AURELIUS. A person of this name was made prefect of Pannonia by Julian about 360 (Amm. Marc., xxi. 10), and may be identical with the man who was consul along with Valentinian in 373 and with the prefect of the city of the same name who is mentioned in an inscription of the time of Theodosius. Four small historical works have been ascribed to him on more or less doubtful grounds—(1) *Origo Gentis Romani*, (2) *De Viribus Illustribus Romæ*, (3) *De Cæsaribus*, (4) *De Vita et Moribus Imperatorum Romanorum excerpta ex Libris Sex. Aur. Victoris.* The four have generally been published together under the name *Historia Romana*, but the fourth piece is a *réchauffé* of the third; and, though all are late, there is no sufficient reason to think that they are by one hand. The second was first printed at Naples about 1472, in 4to, under the name of Pliny (the younger) and the fourth at Strasburg in 1505. The first edition of all four was that of A. Schottus (8vo, Antwerp, 1579). The *De Cæsaribus*, which goes from Augustus to Constantius, and claims to be by a man of mean origin who rose to distinction through letters, may be the work of the Sextus Aurelius Victor known to history.

VICTOR AMADEUS, the name of three dukes of Savoy. See SAVOY.

VICTOR EMMANUEL (1820–1878), king of Italy, born at Turin on 14th March, 1820, was the son of Charles Albert, prince of Carignano, who in 1831 became king of Sardinia. He was brought up with some severity and as a strict Catholic; but it was not found possible to interest him in study or intellectual pursuits. In 1842 he was married to Adelaide, daughter of the Austrian grand-duke Rainer, his father at that time desiring to improve his relations with Austria. The young man took no part in politics, but showed from the first the characteristics of an energetic soldier. After the Austrian occupation of Ferrara in 1847 he was among those who pressed for an immediate declaration of war; and, when a year later hostilities broke out, he threw himself into the struggle heart and soul. At Goito, where he was wounded, his reckless bravery turned the tide of battle; and in every encounter he was to be seen in the thickest of the fight. During the armistice that followed the defeat of Custozza (25th July), he was engaged in the reorganization of the Sardinian army. The abdication of his father on the evening of the battle of Novara (23d March, 1849) made him king of a ruined state. From Radetzky he obtained some mitigation of the hard terms at first demanded by the conqueror, especially in the withdrawal of the Austrian claim that the Sardinian constitution should be abolished. It was the maintenance of this constitution, at a time when reaction swept away every other vestige of representative government in Italy, that gained for Victor Emmanuel the title of the honest king (*re galantuomo*) and won for him the confidence of the Italian nation, and ultimately the Italian crown. In the bitter days that followed Novara, the king, calumniated, misunderstood, and charged like his father with treachery, showed a noble forbearance and a self-mastery that could hardly have been expected from his passionate uncultured nature. Though in D'Azeglio and Balbo he had excellent friends and advisers, it was not till 1852 that the accession of CAVOUR (*q.v.*) to power gave him a man of great political genius for his guide. From that time the career of Victor Emmanuel became what Cavour made it. While ecclesiastical reforms, which brought upon the king and minister the execration of the church, laid the foundation for all future social and economical advance, the alliance of Sardinia with England and France in the Crimean War secured for Italy the interest of the Western powers, which Austria by its inaction and its half-measures had forfeited. Meanwhile his mother, his wife, and his brother died within four weeks of each other; and the clericals exulted in this manifestation of an offended Providence. At the end of 1855, while the allied troops were still in the East, Victor Emmanuel visited Paris and London. In 1859 Cavour's object was attained and France united with Sardinia against Austria, the king, sorely against his will, giving his daughter Clotilda in marriage to Jerome Napoleon. Victor Emmanuel met Napoleon III. at Genoa on 13th May, and on the 30th fought at the head of a body of Sardinians and Zouaves at the battle of Palestro. After the victory of Magenta (4th June) the allied monarchs entered Milan, where Victor Emmanuel for the first time saw Garibaldi. In the crowning victory of 24th June, while the French were engaged at Solferino, the king with his Italians carried the village of San Martino. The peace of Villafranca left Venetia and the Quadrilateral to Austria. The extraordinary events of the next year united all Italy, with the exception of Rome and of what still remained to Austria, under the patriotic king, who was now excommunicated by the pope (see ITALY, vol. xiii. p. 500). A scene of great violence had passed between the king and Cavour when the peace of Villafranca was accepted by the former; but their old friendship was soon restored, and the death of Cavour in 1861 plunged Victor Emmanuel in the deepest grief. The Prussian alliance of 1866 incorporated Venetia with Italy. The personal desire of the king to assist Napoleon III. in the war of 1870 gave way before the wiser counsels of his ministers; and the entry of his troops into Rome after the disasters of the French army and the withdrawal of the French garrison completed Victor Emmanuel's task and the union of Italy. He lived for eight years more, reigning always as a constitutional king, and preserving amidst the splendors of a great court the simple tastes of his early life. He died at Rome of a fever on 9th January, 1878, and lies entombed in the Pantheon.

Plate VI.

VICTORIA, a British colony occupying the southeastern corner of Australia; its western boundary is the 141st meridian; on the east it runs out to a point at Cape Howe, in 150° E. long., being thus rudely triangular in shape; the river Murray constitutes nearly the whole of the northern boundary, its most northerly point being in 34° S. lat.; the southern boundary is the coast-line of the Southern Ocean and of Bass Strait; the most southerly point is Wilson's Promontory in 39° S. lat. The greatest length east and west is about 480 miles; the greatest width, in the west, is about 250 miles. The area is officially stated to be 87,884 square miles.

Coasts.

The coast-line may be estimated at about 800 miles. It begins at the 141st meridian with bold but not lofty sandstone cliffs, worn into deep caves and capped by grassy undulations, which extend inland to pleasant park-like lands. Capes Bridgewater and Nelson form a peninsula of forest lands, broken by patches of meadow. To the east of Cape Nelson lies the moderately sheltered inlet of Portland Bay, consisting of a sweep of sandy beach flanked by bold granite rocks. Then comes a long unbroken stretch of high cliffs, which owing to insetting currents have been the scene of many calamitous wrecks. Cape Otway is the termination of a wild mountain range that here abuts on the coast. Its brown cliffs rise vertically from the water; and the steep slopes above are covered with dense forests of exceedingly tall timber and tree ferns. Eastwards from this cape the line of cliffs gradually diminishes in height to about twenty to forty feet at the entrance to Port Phillip. Next comes Port Phillip Bay, a plan of which is given under MELBOURNE, vol. xv. p. 844. When the tide recedes from this bay through the narrow entrance it often encounters a strong current just outside; the broken and somewhat dangerous sea thus caused is called "the Rip." East of Port Phillip Bay the shores consist for fifteen miles of a line of sandbanks; but at Cape Schanck they suddenly become high and bold. East of this comes Western Port, a deep inlet more than half occupied by French Island and Phillip Island. Its shores are flat and uninteresting, in some parts swampy; but all the land is owned and most of it occupied. The bay is shallow and of little use for navigation. The coast continues rocky round Cape Liptrap. Wilson's Promontory is a great rounded mass of granite hills, with wild and striking scenery, tree-fern gullies, and gigantic gum-trees, connected with the mainland by a narrow sandy isthmus. At its extremity lie a multitude of rocky islets, with steep granite edges. North of this cape, and opening to the east, lies Corner Inlet, which is dry at low water. The coast now continues low to the extremity of the colony. The slight bend northward forms a sort of bight called the Ninety Mile Beach, but it really exceeds that length. It is an unbroken line of sandy shore, backed by low sand hills, on which grows a sparse dwarf vegetation. Behind these hills come a succession of lakes, surrounded by excellent land, and beyond these rise the soft blue outlines of the mountain masses of the interior. The shores on the extreme east are somewhat higher, and occasionally rise in bold points. They terminate in Cape Howe, off which lies Gabo Island, of small extent but containing an important lighthouse and signalling station.

Surface.

The western half of Victoria is level or slightly undulating, and as a rule tame in its scenery, exhibiting only thinly timbered grassy lands, with all the appearance of open parks. It is here that the merino sheep are depastured whose wool secures the highest price in the markets of Europe. The northwest corner of the colony, equally flat, is dry and sometimes sandy, and frequently bare of vegetation, though in one part some seven or eight millions of acres are covered with the dense brushwood known as "mallee scrub." This wide western plain is slightly broken in two places. In the south the wild ranges of Cape Otway are covered over a considerable area with richly luxurious but almost impassable forests. This district has been reserved as a state forest and its coast forms a favorite holiday resort, the scenery being very attractive. The middle of the plain is crossed by a thin line of mountains, known as the Australian Pyrenees, at the western extremity of which there are several irregularly placed transverse ranges, the chief being the Grampians, the Victoria Range, and the Sierra Range. Their highest point is Mount Williams (3600 feet). The eastern half of the colony is wholly different. Though there is plenty of level land, it occurs in small patches, and chiefly in the south, in Gippsland, which extends from Corner Inlet to Cape Howe. But a great part of this eastern half is occupied with the complicated mass of ranges known collectively as the Australian Alps. The whole forms a plateau averaging from 1000 to 2000 feet high, with many smaller tablelands ranging from 3000 to 5000 feet in height. The highest peak, Bogong, is 6508 feet in altitude. The ranges are so densely covered with vegetation that it is extremely difficult to penetrate them; only two tracks, impassable for vehicles, intersect them from north to south. But several thousand square miles of this country are still unexplored. About fifteen peaks over 5000 feet in height have been measured, but there are probably many more. Along the ranges grow the giant trees for which Victoria is famous. The narrow valleys and gullies contain exquisite scenery, the rocky streams being overshadowed by groves of graceful tree-ferns, from amid whose waving fronds rise the tall smooth stems of the white gums. Over ten millions of acres are thus covered with forest-clad mountains too wild for settlement. The Australian Alps are connected with the Pyrenees by a long ridge called the Dividing Range (1500 to 3000 feet high).

Victoria is fairly well watered, but its streams are

Rivers.

generally too small to admit of navigation. This, however, is not the case with the MURRAY RIVER (*q.v.*). Echuca is the chief port of the river traffic, and about 250 vessels enter it every year, bringing down from 80,000 to 120,000 bales of wool from the interior. In the lower portion of its course the stream occupies only a narrow winding channel in the midst of its old bed, which now seems like a fertile valley hemmed in on either hand by high cliffs of clay or red earth, or sometimes of beds of oyster shells of vast extent. The navigation of the Murray is greatly impeded by "snags," or trees that have stuck fast in the bed of the river and project a little above or below the surface. But the removal of these obstacles is constantly going on, and consequently the navigation is becoming easier. Of the total length of the Murray 670 miles flow conterminous with Victoria. The Murray receives a number of tributaries from the Victorian side. The Mitta Mitta, which rises in the heart of the Australian Alps, is 150 miles long. The Ovens, rising among the same mountains, is slightly shorter. The Goulburn (340 miles) flows almost entirely through well-settled agricultural country, and is deep enough to be used in its lower part for navigation. The valley of this river is a fertile grain-producing district. The Campaspe (150 miles) has too little volume of water to be of use for navigation; its valley is also agricultural, and along its banks there lie a close succession of thriving townships. The Loddon (over 200 miles) rises in the Pyrenees. The upper part flows through a plain, to the right agricultural and to the left auriferous, containing nearly forty thriving towns, including Sandhurst and Castlemaine. In the lower part of the valley the rainfall is small and droughts are frequent, but farmers are steadily pushing out into it, as the land is very fertile. Recent legislation has provided for the formation of irrigation trusts in these districts of rich soil but small rainfall. To the west of the Loddon is the Avoca river (140 miles). It is of slight volume, and though it flows towards the Murray it loses itself in marshes and salt lagoons before reaching that river.

The rivers which flow southwards into the ocean are numerous. The Snowy river rises in New South Wales and in Victoria flows entirely through wild and almost wholly unoccupied territory. The Tambo (120 miles long), which rises in the heart of the Australian Alps, crosses the Gippsland plains where the land is good, but only a small portion is occupied. The Mitchell river, rising also among the Australian Alps, is navigable to a limited extent. Its lower valley is being rapidly occupied by thriving hop plantations. The Latrobe is a deep clear stream flowing through level country. The Yarra rises in the "Black Spur" of the Australian Alps. Emerging in a deep valley from the ranges, it follows a sinuous course through the undulating plains called the "Yarra Flats," which are wholly enclosed by hills, on whose slopes are some of the best vineyards of Australia; it finds its way out of the Flats between high and precipitous but well-wooded banks, and finally reaches Port Phillip Bay below Melbourne. Owing to its numerous windings its course through that city and its suburbs is at least thirty miles. Nearer to the sea its waterway, formerly available for vessels drawing 16 feet, has now been deepened so as to be available for vessels drawing 20 feet. The Barwon, farther west, is a river of considerable length but little volume, flowing chiefly through pastoral lands. The Hopkins and Glenelg (280 miles) both water the splendid pastoral lands of the west, the lower course of the former passing through the fertile district of Warrnambool, well known throughout Australia as a potato-growing region.

Lakes.

In the west there are Lakes Corangamite and Colac, due north of Cape Otway. The former is intensely salt; the latter is fresh, having an outlet for its waters. Lakes Tyrrel and Hindmarsh lie in the plains of the northwest. In summer they are dried up, and in winter are again formed by the waters of rivers that have no outlet. In the east are the Gippsland lakes, formed by the waters of the Latrobe, Mitchell, and Tambo being dammed back by the sandhills of the Ninety Mile Beach. They are connected with Bass Strait by a narrow and shifting channel through a shallow bar; the Government of Victoria has done a great deal of late years to deepen the entrance and make it safer. The upper lake is called Lake Wellington; a narrow passage leads into Lake Victoria, which is joined to a wider expanse called Lake King. These are all fresh-water lakes, and are visited by tourists for the sake of their scenery, which, though monotonous, has a certain impressiveness. The surrounding country is being rapidly settled and utilized.

Climate.

Victoria enjoys an exceptionally fine climate. Roughly speaking, about one-half of the days in the year present a bright cloudless sky, with a bracing and dry atmosphere, pleasantly warm but not relaxing. These days are mainly in the autumn and spring. During the last twenty years there have been on an average 131 days annually on which rain has fallen more or less (chiefly in winter), but rainy days do not exceed thirty in the year. The average yearly rainfall is about 26 inches. The disagreeable feature of the Victorian climate is the occurrence of north winds, which blow on an average about sixty days in the year. In winter they are cold and dry, and have a slightly depressing effect. But in summer they are hot and dry, and generally bring with them disagreeable clouds of dust. The winds themselves blow for periods of two or three days at a time, and if the summer has six or eight such periods it becomes relaxing and produces languor. These winds cease with extraordinary suddenness, being replaced in a minute or two by a cool and bracing breeze from the south. The temperature often falls 40° or 50° Fahr. in an hour. The maximum temperature occurs in February, averaging 105.6° Fahr. in the shade. The minimum is in July, when the thermometer registers as low as 30°. The mean for the whole year is 57.3.° The temperature never falls below freezing-point, except for an hour or two before sunrise in the coldest month. Snow has twice been known to fall in Melbourne for a few minutes, in 1849 and 1882. It is common enough, however, on the plateau: Ballarat, which is over 1000 feet high, always has a few snow storms, and the roads to Omeo among the Australian Alps lie under several feet of snow in the winter. The general healthiness of the climate is shown by the fact that the average death-rate for the last five years has been only 14.37 per thousand of the population. The rainfall of the colony varies considerably. On the table-land it averages about 40 inches, at Melbourne 25.44 inches, along the Murray basin 20 inches, and in the "Wimmera" or northwest corner not more than 15 inches.

Geology.

Victoria rests throughout on a bed of coarse granite, which is exposed in many parts by the denudation of the overlying strata. Above this lies a bed of Silurian rocks, which seems to have at one time extended over the whole area, and still forms the surface of a great portion of the colony, especially in the northeast. Other Palæozoic strata are represented by only one small patch of Devonian at Mount Tambo in the Australian Alps, and by small isolated beds of Carboniferous strata along the valley of the Mitchell river. The Mesozoic strata overlie the Silurian along the coast, being represented by beds of Upper New Red Sandstone of considerable thickness. These extend from Cape Otway as far east as Corner Inlet, and sections of them are prominent features where the coasts are rocky. The other Mesozoic strata are absent. Miocene beds occur in patches near Ballarat, near Warrnambool, and in some parts of Gippsland. These are unimportant, however, compared with the Pliocene formations, which cover a very large part of the colony, notably the great plains of the Wimmera and the Murray valley. They also occur in smaller areas over the Silurian rock, either as cappings of prominences, that were left as islands when the waves of Post-Tertiary seas washed away the rest of the beds or else as "leads," *i.e.*, the beds carved out of Silurian strata by rivers of Mesozoic periods, but filled in during Pliocene times by deposits of debris from the mountains. These have been protected by their sunken position when the great bulk of the Pliocene beds were washed away. It is from these old river beds that the alluvial gold of Victoria is got. This gold was evidently at one time contained in veins of auriferous quartz which were worn down and carried into the streams. There the heavy particles of gold gathered in the hollows, forming those collections known to miners as pockets. In some parts of Victoria vast sheets of lava overlie the Pliocene beds. These are most prominent in the southwestern corner. The district round Warrnambool possesses eighty-three extinct volcanoes, and there were probably many more whose craters have been completely denuded. The volcanoes were of no great height, but from them issued sheets of glowing lava, covering the plains for hundreds of square miles. At Ballarat the mining shafts descend through four beds of basalt divided from one another by deposits of clay. These represent four distinct outflows of lava in comparatively recent geologic times.

Minerals. During 1886, 665,196 oz. of gold were obtained, of the value of £2,660,780 [$12,931,390.80]. The total yield from 1851 to 1886 was 54,393,182 oz. of the value of about £217,570,000 [$1,057,390,200]. The number of miners is about 26,000 of whom nearly 5000 are Chinese. These devote themselves in nearly equal proportions to alluvial mining and quartz mining. But little is now done in the way of merely surface alluvial digging. The shafts are carried down to the beds of ancient rivers, where the layers of what are called "wash dirt" vary in thickness from 1 to 12 feet, yielding from ½ to 3 oz. per cubic yard. Quartz mining is rapidly increasing in extent, though the total quantity of gold obtained is steadily decreasing and the expense of getting it is increasing, for the shafts are becoming of excessive depth. One at Stawell penetrates 2409 feet below the surface; two others exceed 2000; and there are in all 17 shafts each over 1000 feet in depth. The average yield of this quartz has been of late about 10 dwts. to the ton. About one-third of the area of Victoria is supposed to be auriferous, but only 1300 square miles have as yet been worked. Besides gold, Victoria produces a little tin, copper, and antimony, and, in still smaller quantities, zinc, lead, cobalt, bismuth, and manganese. Iron ore is being smelted, but the industry has not yet reached a paying condition. Great efforts are being made to discover coal-fields or to open up those that are known to exist. The total value of the coal raised in the colony up to date (1888) is only £17,000 [$82,600]. A promising 5-foot seam is, however, now being worked in Gippsland.

Flora. The native trees belong chiefly to the *Myrtaceæ*, being largely composed of *Eucalypti* or gum trees. There are several hundred species, the most notable being *Eucalyptus amygdalina*, a tree with tall white stem, smooth as a marble column, and without branches for 60 or 70 feet from the ground. It is singularly beautiful when seen in groves, for these have all the appearance of lofty pillared cathedrals. These trees are among the tallest in the world, averaging in some districts about 300 feet. The longest ever measured was found prostrate on the Black Spur; it measured 470 feet in length; it was 81 feet in girth near the root. *Eucalyptus globulus* or blue gum has broad green leaves, which yield the eucalyptus oil of the pharmacopœia. *Eucalyptus rostrata* is extensively used in the colony as a timber, being popularly known as red gum or hard wood. It is quite unaffected by weather, and almost indestructible when used as piles for piers or wharves. Smaller species of eucalyptus form the common "bush." Melaleucas, also of *Myrtacea* kind, are prominent objects along all the coasts, where they grow densely on the sandhills, forming "ti-tree" scrub. *Eucalyptus dumosa* is a species which grows only 6 to 12 feet high, but with a straight stem; the trees grow so close together that it is difficult to penetrate the scrub formed by them. Eleven and a half million acres of the Wimmera district are covered with this "mallee scrub," as it is called. Recent legislation has made this land easy of acquisition, and the whole of it has been taken up on pastoral leases. Five hundred thousand acres have recently been taken up as an irrigation colony on Californian principles and laid out in 40-acre farms and orchards. The *Leguminosæ* are chiefly represented by acacias, of which the wattle is the commonest. The black wattle is of considerable value, its gum being marketable and its bark worth from £5 [$24.30] to £10 [$48.60] a ton for tanning purposes. The golden wattle is a beautiful tree, whose rich yellow blossoms fill the river-valleys in early spring with delicious scent. The *Casuarinæ* or she-oaks are gloomy trees, of little use, but of frequent occurrence. Heaths, grass-trees, and magnificent ferns and fern-trees are also notable features in Victorian forests. But European and subtropical vegetation has been introduced into the colony to such an extent as to have largely altered the characters of the flora in many districts.

Fauna. The indigenous animals belong almost wholly to the *Marsupialia*. Kangaroos are tolerably abundant on the grassy plains, but the process of settlement is causing their extermination. A smaller species of almost identical appearance called the wallaby is still numerous in the forest lands. Kangaroo rats, opossums, wombats, native bears, bandicoots, and native cats all belong to the same class. The wombat forms extensive burrows in some districts. The native bear[1] is a frugivorous little animal, and very harmless. Bats are numerous, the largest species being the flying fox, very abundant in some districts. Eagles, hawks, turkeys, pigeons, ducks, quail, snipe and plover are common; but the characteristic denizens of the forest are vast flocks of parrots, parakeets, and cockatoos, with sulphur-colored or crimson crests. The laughing jackass (giant kingfisher) is heard in all the country parts, and magpies are numerous everywhere. Snakes are numerous; but less than one-fourth of the species are venomous, and they are all very shy. The deaths from snake-bite do not average 2 per annum. A great change is rapidly taking place in the fauna of the country owing to cultivation and acclimatization. Dingoes have nearly disappeared, and rabbits, which were introduced only a few years ago, now abound in such numbers as to be a positive nuisance. Deer are also rapidly becoming numerous. Sparrows and swallows are as common as in England. The trout, which has also been acclimatized, is taking full possession of some of the streams.

Live stock. In 1878 Victoria possessed nearly eleven millions of sheep, Victorian sheep give an exceptionally large yield of wool, and their fleeces obtain a higher price (on the average 6s. 2d.) [$1.50] than any other grown in Australia. The colony has one and a quarter millions of cattle, three hundred and eight thousand horses, and about a quarter of a million of pigs.

Agriculture. There were in 1887 about 38,000 farms in the colony, containing over 2,417.157 acres of land actually cultivated; in almost all farms there is much land that is not actually tilled. Every year, however, a larger and larger proportion is brought under the plough. In the year ending March, 1887, the crops were as follows: wheat, 12,100,036 bushels; oats, 4,256,079 bushels; barley, 827,852 bushels; potatoes, 170,661 tons; and hay, 483,049 tons. The average produce per acre of wheat crop was 11½ bushels; the average per acre of oats, 23 bushels; of barley, 22 bushels; of potatoes, 3½ tons. There are 10,300 acres of vineyards, producing 986,041 gallons of wine, and this industry is fast increasing. The hop plantations in 1887 yielded 5023 cwts. of hops. The following crops are being more or less experimented with: arrowroot, beetroot, flax, mangel wurzel, mustard, olives, poppies, oranges and some other fruits. In the same year there were produced 12,008 cwts. of tobacco. Almost every fruit is grown more or less, but the banana and orange cannot be considered commercially successful. Apples, pears, peaches, grapes, loquats, mulberries, plums, gooseberries, strawberries, melons, apricots, raspberries, cherries, currants, quinces, almonds, figs, walnuts, all grow well and are in common use. Bananas, pine-apples, oranges, and passion fruit are cheap, but they come from the northern colonies. Tomatoes are plentiful and cheap, being easily grown in all parts of the colony.

Communication. The central half of Victoria is well supplied with a close network of railways, whilst several long lines branch out into the less settled districts east and west. A line parallel to the coast, joining Melbourne to Bairnsdale, is sufficient for the Gippsland traffic. From Sale a number of short lines are being constructed for the convenience of the surrounding district. To the west there is a line 270 miles long joining Melbourne to Portland, giving off short branches on both sides. Three lines are being steadily pushed forward to the northwest into the Wimmera district. In 1887 there was a total length of 1880 miles open for traffic. The average cost of the lines now in operation has been £11,748 [$57,095.28] per mile, but all the more recently constructed lines have not exceeded £5000 [$24,300.00] per mile. The receipts for the year 1886–1887 were £2,453,078 [$11,921,959.08], and the working expenses £1,427,116 [$6,935,783.76]. All the lines are on a uniform gauge of 5 feet 3 inches, and they all belong to the state, being managed by a special board of three commissioners. Communication with Sydney, 573 miles distant, is effected by rail in 19 to 25 hours, and with Adelaide in about 20 hours.

The well-settled parts of the colony are excellently supplied with macadamized roads, which are constructed and repaired by shire councils, whose chief function it is to raise revenues, each from its own district, to support the roads in that district. The less settled districts have tracks on which riding or driving is excellent after fine weather, but not after much rain.

Victoria has 420 telegraph stations, connected by 4096 miles of line. Melbourne is connected with every town or borough in Australia, Tasmania, and New Zealand. It is also joined with London, the length of line being 13,695 miles. The shortest recorded time for the transmission of a message along this line is 32 minutes; the average time is about three hours. There are about 1300 telephone wires in use in the colony, chiefly in Melbourne.

---

[1] [This is the Koala, and is not a bear. See MAMMALIA, vol. xv. p. 385.—AM. ED.]

In 1886 the colony had 1429 post-offices, through which there passed 38,392,414 letters and post-cards, 17,482,490 newspapers, and 6,926,525 packets.

Trade. Victoria is fully committed to the system of "protection to native industry." In 1886 the value of its manufactures was £13,370,000 [$64,978,200.00], of which over £2,250,000 [$10,935,000.00] worth was exported. The number of establishments was 2770, and the number of hands employed 45,770. The total value of the exports for 1886 was £11,795,321 [$57,324,774.06], the chief items of which were wool, £5,028,061 [$24,436,376.46]; gold, £4,309,535 [$20,944,340.10]; live stock, £898,000 [$4,364,280.00]; wheat, £408,000 [$1,982,880.00]; flour, £318,000 [$1,545,480.00]; sugar (brought to Victoria to be refined), £266,779 [$1,296,545.94]; tea, (brought to Melbourne to be re-exported), £395,000 [$1,919,700.00]; machinery, £184,135 [$896,601.96]. The imports in 1886 amounted to £18,530,575 [$90,058,599.36] in value, of which £8,741,275 [$43,482,596.50] were from the United Kingdom, £6,567,403 [$31,917,578.58] from other British colonies, and £3,221,897 [$15,658,419.42] from foreign countries, the United States heading the list with over half a million, chiefly manufactured goods.

Shipping. In 1886 2307 vessels entered at Victorian ports (chiefly Melbourne) and 2324 cleared, the tonnages being 1,848,058 and 1,887,329 respectively. Of the vessels that entered 1684 and of those that cleared 1721 were colonial, their respective tonnages being 958,833 and 983,295. Of British vessels there entered 407 (648,026 tons) and cleared 382 (661,833 tons). There is no shipbuilding of importance carried on in Victoria, only 4 small vessels having been built in 1886, with a total tonnage of 420. But there is a brisk trade in repairs, there being several good yards, and the Government possesses at Williamstown a graving dock which admits vessels 500 feet long, the depth of water being 27 feet.

Banks. Eleven banks of issue in Victoria had in 1886 notes to the extent of £1,399,208 [$6,800,150.00] in circulation; their deposits bearing interest amounted to £23,999,791 [$116,638,984.26], not bearing interest (current accounts), £7,239,681 [$35,184,849.66]. The total liabilities amounted to £33,085,989 [$160,797,906.54], the assets to £41,170,989 [$200,091,006.54]. The average rate of annual dividends is 12¼. There are besides six banking companies which do not issue notes, and two distinct systems of savings banks. The ordinary savings banks had in 1886 15 branches with 111,031 depositors, who owned £2,322,959 [$11,289,580.74] of deposits. There were 264 branches of the post-office savings banks, with 78,328 depositors, owning £1,266,957 [$6,157,411.02]. But perhaps the most popular institution for the investment of money among persons of moderate means is the building societies, of which 60 were returned in 1886, with 19,907 members, holding £2,910,792 [$14,147,323.92] as deposits. These societies act as banks, and members have their current accounts with them. The total sums deposited in banks and building societies in 1888 amounted to forty millions [$194,400,000.00].
